FARM, SCHOOL AND CHURCH BELLS.

THE STEEL COMPOSITION BELLS made by Blymyer, Norton & Co., of Cincinnati, rival the Copper and Tin Bells in purity, richness, and volume of tone; are equally durable; and cost less than one-third as much. Hundreds are now in use in various parts of the United States and Canada. None have failed to give satisfaction. They are made of the best quality of metal; and the mountings are of the best material and finish.

PRICE LIST:

They are delivered on board Cars or Boat at Chicago, for the following prices in American money:—

Diameter.	Weight.	Price.
14 inches.	50 lbs.	$ 8 00
16 "	90 "	12 00
18 "	100 "	14 00
20 "	130 "	18 00
24 "	200 "	25 00
28 "	400 "	60 00
36 "	800 "	120 00
40 "	1,000 "	175 00

Orders, enclosing the money, may be addressed to

A. T. BATES & CO.,
195 Washington Street, Chicago.
Or,

MILLER'S
INFALLIBLE

TICK DESTROYER FOR SHEEP!

DESTROYS the TICKS; cleanses the skin; strengthens and promotes the growth of the wool, and improves the condition of the animal.

It is put up in boxes at 35c., 70c., and $1, with full directions on each package. A 35c. box will clean twenty sheep.

HUGH MILLER & Co.,
167 King Street East. Medical Hall, Toronto.

Paxton, Tate & Co., Port Perry, Ont.,

MANUFACTURERS OF THE

MARSH HARVESTER!
AGRICULTURAL IMPLEMENTS
OF ALL KINDS,

STAVE & SHINGLE MACHINERY,
OSCILLATING MULLEY SAWS,
TURBINE WATER WHEELS,
MILL CASTINGS, etc., etc.,

MADE TO ORDER.

☞ *Repairing of all kinds promptly attended to.* ☜

WARRANTY.

We warrant the Marsh Harvester to be well made, of good material, and when properly used, not liable to get out of repair; to be a good grain-cutting machine upon which two experienced binders can bind in average grain, on suitable ground, from eight to twelve acres in twelve hours; and that it will work on as rough ground as any other Reaper.

PAXTON TATE & CO.

Port Perry, March 28, 1868. v5-7-tf

Markets.

Toronto Markets.

"CANADA FARMER" Office, April 29th, 1868.

The produce market since our last review has been dull and uninteresting. Although navigation is now open there has been little or nothing doing.

Wheat—The market remains unchanged. Holders are firm at $1 66 for cargo lots of spring, with buyers at $1 64 and $1 65. One small cargo lot of spring sold early in the week at $1 64, but the sample was not choice; and a few car loads sold at $1 65. In fall wheat there was nothing doing. Street prices are: spring $1 64 and $1 65, midge proof $1 66. No fall wheat coming in.

Oats—There has been nothing doing during the past week in this grain. Quotations are nominal.

Barley—The receipts of this grain are very small, and stocks being exhausted there is nothing doing. The nominal quotations are $1 40 to $1 45 for choice barley.

Peas—The market is quiet but firm. Lots are held at 92c, with a sale at 90c for a lot of 1,000 bushels.

Seeds—The market is quiet but firm. We quote clover firm at $4, timothy, $1 50 to $2 25, flax seed, $1 25 to $1 60.

Flour—The market remains dull and unchanged. During the past week there has been very little doing—hardly enough to establish quotations. For No. 1 superfine holders are asking $7 15. A sale took place yesterday at that figure. In extra and superior there was nothing doing.

Oat Meal—The market remains nominally unchanged.

Pork—The market is quiet. A slight dullness has taken place. We, however, do not change our quotations. Mess, $20 to $21; Prime Mess nominal at $16 to $17.

Cut Meats—In fair demand. Smoked hams and rolls 12 to 12½c city cured. Smoked shoulders, 9 to 10c.

Butter—New in good local demand. No good old in market. We quote for sweet yellow in large rolls or tubs 21c to 25c; old, if poor quality, offering at 14 to 15c.

Cheese—Unchanged, 10½c to 11c.

Bacon—Steady at the advance; 9½c offered for city Cumberland.

Eggs—Scarce and wanted at 14c.

Hides, Skins and Wool.—The following are the prices paid for skins:—Green Butchers' 5½c; Farmers', 6c; Calfskins, 10c; Sheepskins, $1 to $1 30.

The following are the selling prices of hides:—No. 1 inspected, 7¾ to 8c; Calves Skins, 12c.

Wool is dull. Pulled sells at 23c. Fleece, none in the market.

THE CATTLE MARKET.

There has been an average trade done in cattle during the past week. Prices remain unchanged. 1st class, $3 per cwt. 2nd class, $2. 3rd class, $6.

Sheep—Have been in demand and sold as follows:—1st class, $7 each. 2nd class, $6. 3rd class, $5.

Lambs—Are beginning to arrive freely. Prices are:—1st class, $3. 2nd class, $2 to $2 50. 3rd class, $1 50 to $2 00.

Calves—Of the better class have been scarce and in demand. We quote:—1st class, $8 each. 2nd class, $6. 3rd class, $2 00 to $3 50 each.

Montreal Markets.—*Flour*—Superior extra, $8 to $8 25; extra, $8 to $8 10; fancy, $7 85; Welland Canal, superfine, $7 61; to $7 00; superfine No. 1 Canada wheat, $7 55 to $7 65; superfine No. 1 Western wheat, $7 55 to $7 75; superfine No. 2 Western wheat, $7 30 to $7 35; bag flour per 100 lbs. $3 60 to $3 70.—*Wheat.*—Canada fall, none; spring $1 72 to $1 73; Western, $1 65 to $1 70.—*Oats.*—Per 32 lbs., 49c to 50c.—*Barley.*—Per 48 lbs $1 15 to $1 20.—*Butter.*—Dairy, 18c to 21c; store packed, 18c to 22c.—*Ashes.*—Pots, $5 75 to $5 80; pearl, $6. *Pork.*—Mess $21,50 to $22 00; prime mess, $16 50 to $16 75; primo $15 75 to $16.—*Dressed Hogs:*—none.—*Peas.*—47c to 98c.—*Rye Flour.*—$6 00 to $6 10.

New York Produce Market.—*Flour*—Dull, receipts 5,200 barrels and 5,900 bags; sales, 6,800 bbls, at $9 to $9 65 for super State and Western; $10 10 to $10 60 for common to choice extra State; $10 10 to $11 25 for common to choice extra Western.—*Wheat*—More active; receipts, 16,200 bushels; sales, 51,000 bushels at $2 45 to $2 46; No. 2 spring, $2 55 to $2 60; No. 1 spring at $3 15; white Michigan, $3 10; white Canada at $2 50, No. 1 and 2 spring mixed.—*Rye*—Quiet.—*Corn*—Dull; receipts, 109,693 bushels; sales, 63,000 bushels at $1 12 to $1 16 for new mixed Western afloat; $1 16 to $1 17 old afloat.—*Barley*—Quiet; receipts $18,100 bushels.—*Oats*—Quiet; receipts, 26,075 bushels; sales, 28,000 bushels at 64½c. for Western in store; 65c afloat.—*Provisions*—Pork firmer and in fair demand at $29 15 to $29 37 for new mess; $27 50 to $28 50 for old ditto.—*Lard*—Firmer, and quiet at 18¾ to 18¾c.

Milwaukee Markets, April 29.—Wm. Young and Co.'s report.—*Wheat*—Receipts, 48,000 bushels; shipments, 3,000 bush. No. 1 lower, but active and firm at $2 14; No. 2 lower, but active and firm at $2 04.—*Flour* firm at $9 50.—*Pork* firm at $28.—*Freights* firm at 12c.

Chicago Markets, April 29.—Wm. Young & Co.'s report.—*Wheat*—Receipts, 43,000 bushels; shipments, 9,000 bushels; No. 2 firm at $2 12.—*Corn* active at 86½c.; receipts, 92,000 bushels; shipments, 111,000.—*Pork* firm at $28 50.

THE CANADA FARMER is printed and published on the 1st and 15th of every month, by the GLOBE PRINTING COMPANY, at their Printing House, 26 and 28 King Street East, Toronto, Ontario, where all communications for the paper must be addressed.

☞ Subscription Price $1 per annum, (POSTAGE FREE,) payable in advance. Bound volumes for 1864, 1865, 1866 and 1867, may be had for $1 20 each. Subscribers may either begin with No. 1 of the present Volume, or with the first No. of any preceding volume. No subscriptions received for less than a year, and all commence with the first number for the respective years.

CLUBS will be furnished at the following rates:—

TEN COPIES for..... NINE DOLLARS.
TWENTY COPIES for..... SIXTEEN DOLLARS.
FORTY COPIES for..... THIRTY DOLLARS.
ONE HUNDRED COPIES for..... SEVENTY DOLLARS

To Agricultural Societies ordering more than 125 copies, THE FARMER will be sent at SIXTY CENTS.

THE CANADA FARMER presents a first-class medium for agricultural advertisements. Terms of advertising, 20 cents per line space. Twelve lines' space equals one inch. No advertisement taken for less than ten lines' space.

Communications on Agricultural subjects are invited, addressed to "*The Editor of the Canada Farmer,*" and all orders for the paper are to be sent to GEORGE BROWN,
Managing Director.

THE CANADA FARMER.

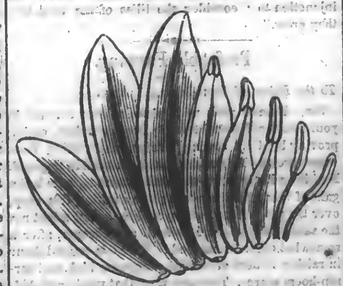
The Field.

The Reproductive Organs of Plants.

In former articles we have given a brief outline of the leading principles of vegetable structure and growth, under the heads of the Seeds of Plants, Germination, the Root, the Stem, and Leaves. To complete the summary, it now only remains to notice the Flower, or reproductive system of Plants. There is the closest analogy between a flower and an ordinary branch. Both spring from a bud, on similar situations of the stem; both follow the same order of arrangement, and in irregular or redundant growths one is frequently transformed into the other. The proofs and illustrations of the analogy of the two structures are numerous and extremely interesting, but cannot be more than merely alluded to in a notice of this brief and elementary character. It will be sufficient here to state that the flower is a branch, shortened and modified in a particular manner for the purpose of producing not buds for the growth of the individual, as in the case of ordinary branches, but seeds capable of independent growth, and destined for the perpetuation of the species.

As the whole flower is a modified branch, so are the separate parts of a flower modifications of leaves. The transition, indeed, is often very beautifully manifest, and the frequent substitution of one for the other, affords striking evidence of the truth of the theory. The parts of a complete flower are as follows:—An outer circle of small leaves, usually green, forming the flower-cup or *calyx*. The separate leaflets of the calyx are called *sepals*. Within this is another circle of generally larger leaflets, usually of some bright colour, and of very delicate texture. The whole forms the *corrolla*, and the separate members are termed *petals*. Every one at all familiar with these beautiful formations knows that there is an endless diversity in both these parts of a flower. Sometimes the calyx is absent or deciduous. In other instances it is persistent after the corrolla has perished, and forms either a covering or a conspicuous appendage of the fruit. Again, this outer circle may assume the bright hues and the general appearance of the corolla, as in the fuschia and other familiar examples; or it may indeed take the place of the corrolla altogether, the latter being absent, or only rudimentary in the form of minute and inconspicuous scales.

These, though commonly the most showy portions of the flower, are nevertheless but the outer covering of the more important parts. They are merely the floral envelopes. The essential parts are yet to be noticed. Springing usually from the base of the petals, but sometimes adherent to them more or less, is a circle of delicate organs called stamens, consisting of a slender stalk or *filament*, supporting a slightly enlarged head called the *anther*, usually two-lobed, and filled with a powdery substance, called *pollen*, which, when the flower is fully developed, is discharged through a fissure or opening of the anther,



and serves to fertilize the innermost organ of the flower containing the ovule or infant seed. This centre portion is the seed-vessel or pistil, and consists, where all the parts are fully developed, of the

ovary at the base, enclosing the seed, and bearing a single or divided prolongation from the summit, called the *style*, capped by a slightly dilated head, the *stigma*, which is moist, and destitute of the usual covering or cuticle that envelopes nearly every other part of a plant. As might be expected, the filament of the anther and the style of the pistil are not always present, neither being essential to the organ. Where the flower is comparatively erect, the stamens usually surmount the pistil, and the pollen from the anther drops on to the adhesive surface of the stigma below. But in pendulous or drooping flowers, where the relative position of the parts is reversed, a corresponding modification is seen in the development of these organs. The style is then much lengthened, and carries its head beyond the stamens, so that, as the flower hangs downwards, the latter will still be above the stigma, in such a position as to shed their contents on the stigma below them. A beautiful instance, one among myriads, of the perfect and marvellous adaptation in even the most minute details of the handiwork of the great Creator. There are no oversights or mistakes in His creations.

It is easy to trace the analogy of the first of the floral envelopes, the calyx, to a circle of leaves, the transition and resemblance being often very manifest; and again, it is not difficult to see the close analogy of the next circle of petals to the sepals of the calyx, and consequently also to leaves. The transformation of structures essentially similar into stamens, and even into pistils, is equally evident in nature; and one of the best examples of this analogy is found in the white water lily (*nymphæa odorata*), where the gradual transition can be very distinctly seen, as shown in the accompanying illustration, which represents a single member of the different circles of the flower. In this and similar flowers the circles are multiplied, and the gradation becomes more evident than in ordinary flowers where the parts are fewer and distinct. Any one can verify this statement by examining a flower of this beautiful plant, which is not uncommon in still and shallow Canadian waters. In our orchards, gardens, and fields, we also frequently meet with monstrous growths, in which the very central parts of the flower revert to their original type, and expand into green leaves, or even slender leaf-bearing branches. One of the nearest approximations to the leaf type of the pistil, is seen in the pod of the pea and other leguminous plants, in which the resemblance to a leaf folded towards and bearing buds on its edges is very apparent.

The accompanying illustration of the Spring Beauty (*Claylonia Caroliniana*), almost the only common blossom to be met with at the present time, though not a flower of the most regular type, may nevertheless serve to show clearly the several parts which have been enumerated.

The members of both calyx and corrolla are frequently coherent, forming cups or tubes of various forms with a lobed and expanded border. The

anther, and the pistil, are the only essential organs of the flower, and are sometimes the only parts present. In the flower of grasses the coverings of these essential structures are mere scales. Usually the stamens and pistil coexist in the same flower; but sometimes they are separated, one kind of flower bearing only stamens, and another only pistils. We see an example of this in maize, in some strawberries, in the hop, and other well-known plants. In some instances the two kinds of flowers are found on the same plant, and in others they grow on separate plants. In the latter case it is necessary that both kinds of plants grow near each other, or the seeds, even though the fruit may ripen, will prove infertile. Insects, hovering from plant to plant, and carrying with them the pollen of the pertilizing flowers to the stigma of the seed-bearing flowers, become the unconscious agents in impregnating the latter and rendering their seeds productive. In artificial cultivation, man sometimes controls this reproductive process in plants, and by applying the pollen of one variety to the stigma of another, obtains from the seed thus fertilized a cross or hybrid, partaking in a mixed degree of the qualities of both parents. This is called hybridization, and has been turned, both in flower and fruit culture, to very useful account. Important results have also been gained, and may yet be still further extended by its application to the cultivation of field products, and new and hardy varieties of grain may thus be obtained. Of course there is a limit to the extent to which this crossing of varieties and species can be carried. Mules, even in the vegetable kingdom, are apt to become infertile, a provision made by nature for the obvious purpose of preventing the confusion, and indeed the extinction of specific characters among plants as well as animals.

As soon as the ovule has been fertilized, the function of the flower ceases; the fertilizing agents and the floral coverings commonly perish, and the resources of the plant are concentrated in maturing the fruit, that is, in preparing the seed for its independent life. At the time of flowering the vegetation of the plant is in fullest vigour; the subsequent processes are exhausting, and the plant either dies or needs a season of rest. We should draw from this consideration one practical lesson at least, in the case of grasses, clovers, and other crops which are employed as fodder. If we wish to secure these in their very best condition, when they are most fully charged with nutritive juices, we should select for cutting, the time when they are in flower, before the blooms have begun to fade, and the seed-maturing processes, which exhaust the sap of the plant so materially, have commenced.

The endless varieties presented by the perfect fruit throughout the vegetable world, from the minute and almost naked seed, to the gigantic bread fruit, the manner in which the seed is shed, the numberless and curious contrivances for distributing and dispersing these germs of new life, the rich wealth of food thus stored up for the future plant, and ministering at the same time in nature's bountiful profusion to the wants of a higher order of beings, these and a hundred other topics must be passed by without comment, except to indicate the extent and interesting character of the boundless field of enquiry which this department of knowledge opens up to the student of nature. Nor can we allow ourselves in this place to expatiate on the wonderful beauty in form and hue of these perfect gems of the field; but we may, before concluding, just allude to a prosaic view of the subject which may suggest a new idea to some of our readers. Admitting that the lovely colours and shapes of flowers served no other purpose than mere ornament, we should not think the end attained a trivial one, or that the profusion of beauty scattered over the earth was any waste of creative power. But, we believe, there is another and a more directly practical object secured—that these very shapes and hues serve an important purpose in the economy of vegetation. We know that the agency of the sun's rays in many chemical and organic processes is a compound agency, that the different coloured rays possess different properties, and it is natural to infer that the multiform and many-hued cups and chalices into which God's hand has moulded the flowers may be exactly adapted to separate by their peculiar tints, and concentrate by their reflecting surfaces, the special rays of light and heat which the fertilizing process needs in each plant,—that the curve of the corolla, and the blue or the gold of the petals, may be essential elements of a tiny yet perfect laboratory, where light and life are working out their marvellous operations, no less than the artistic finish of a beautiful creation designed to delight the beholder and satisfy the Maker's sense of what is fair and good. This view of the subject may induce the utilitarian to regard with more complacency the beautiful flowers of the earth, while it will detract nothing from the enjoyment of the poet or artist; and like every fresh contemplation of the theme, will invest with a new interest the lesson of the great Teacher, who best knew of what he was speaking when he uttered the injunction to "consider the lilies of the field how they grow."

Profitable Farming.

To the Editor of THE CANADA FARMER:

SIR,—I have read with pleasure two articles in your issues of November and December last, on improving land by sowing turnips, and rotting them where grown. This method has been tried in England. Nesbit, in his lectures, states that some farmers had a gain of thirty shillings an acre, by rotting this crop, over the profit from feeding to sheep. But might not the same thing be done as well, and cheaper, after a somewhat different method? There is much labour in raising an acre of turnips, wages are high, and turnip-hoers scarce. The same work that would cost 10d. in England, will cost a dollar in Canada. After the roots are raised, the operations of pulling, topping, and tailing, storing them in cellars, and lastly, cutting and carrying them to the cattle, are labourious; and after all, nearly nine-tenths of the bulk are water. It is understood by sheep-feeders that 2,240 lbs. Swedish turnips make 14 lbs. of mutton. Then it is said that vegetable manure raises a crop with only half the nitrogen in it that many other manures will give. (See Johnstone's Lectures.) I have raised turnips here for about forty years, and began feeding about 100 lbs. daily, but have gradually reduced the feed to 30 lbs. daily. I believe my fields are in better condition now than they were when I first began with them. The farm was wild, broken with gullies, and swampy, when I began to chop on it. With your permission I will tell how it is now farmed. It is in eleven fields, two of these (22 acres) are in permanent pasture, the other nine fields, averaging 18 acres each, are used thus:—First field in oats, second divided as follows: two acres of potatoes, four of turnips, three of corn, sown thick for soiling, (after the corn is taken off I get a small crop of turnips,) and nine acres of peas or corn. The third field is in barley, or wheat, or both, the fourth in clover, the fifth clover, the sixth clover, the seventh and eighth pasture, and the ninth, clover, finishes the rotation. Most of this land is drained with tiles or wood, some portions of it with stones, in parallel drains at twenty-seven feet apart. The wood is sawn hemlock or cedar, the cost being about the same as that of tiles, say, 1s. 10d. the rod.

Such is my general plan. The details are as follows. To begin with the eighteen acres of oats. This field is ploughed in the fall, sown early with two-and-a-half bushels of oats, harrowed diagonally twice, with a heavy harrow, then dressed with two bushels of ashes, 75 lbs. of salt, one peck of water lime, 50 lbs. of burnt bones, and 40lbs. of sulphate of ammonia. The total cost of top-dressing is £1 2s. 0d. Afterwards harrow twice lengthwise with a common harrow. Fifty or a hundred pounds of sulphate of ammonia may be used. Under this treatment 100 or more bushels of oats may be raised to the acre. I expect seventy bushels. It is presumed there is plenty of lime in the land. If I fallow, when stumping or draining, I lay on 70 bushels of quick-lime on each acre. After that it wants 30 lbs. yearly. I keep the lime clear of yard dung and ammonia. The land should be well ploughed and subsoiled.

The second field is chiefly a hoed crop. Two acres are planted with potatoes. This portion of the land should be ploughed in the fall, twice grubbed and harrowed in the spring, then drilled. Sow the following dressing:—8 bushels of ashes, 1 barrel superphosphate of lime, 100 lbs. of salt, 100 lbs. of plaster, 50 lbs. of burnt bones, and half a bushel of water-lime. Take a round light log and drive spikes in it, and draw it twice along the drill to mix the dressing with the earth. Plant the potatoes in the proportion of about 15 bushels to the acre; cover with the double mould plough. Before they are through the ground, I harrow with light harrows, then sow 50 lbs of sulphate of ammonia, and 100 lbs. of plaster, and afterwards scuffle. They will not want much hoeing. Scuffle again and set up slightly. Two hundred or two hundred and fifty bushels will probably be the return. Four acres are devoted to turnips, which should be wrought in the same way, only the manure is spread before the drills are made. The same manure and dressing are used as for potatoes. The crop with me is not below 800 bushels, nor over 1000 bushels per acre, and at 3d. the bushel leaves but little balance. Of the remaining land, nine acres are in peas. The land is ploughed and harrowed, and two bushels of peas are sown to the acre. The ploughing is four or five inches deep, with a gang plough. Top-dress with 48 lbs. of burnt bones, 200 lbs. of salt, and 300 lbs of plaster. Harrow lightly and roll lightly. The crop may be from 30 to 50 bushels to the acre, 36 bushels being about the average. The rest of this field, amounting to three acres, is planted with corn, sown thick for soiling. This is wrought in the same manner, and dressed as for potatoes. The corn grows very thick, and eight or nine feet high. The crop is worth at least $40 an acre. My cows are fed twice daily, as much as they will eat. It is cut into lengths of five-eighths of an inch. Some turnips are given after the corn is cut.

The third crop is barley or wheat, ploughed in the fall, grubbed in the spring once or twice, and harrowed. Two bushels of barley are sown to the acre, put down with the gang plough or drill, top-dressed with two bushels ashes, 150 pounds salt, forty-eight pounds burnt bones, and one peck of water-lime. Harrow once, roll, and sow grass seeds, consisting of nine pounds red clover, three or four pounds Alsike Clover, five or six quarts of Timothy. Harrow lightly, mix 150 pounds of plaster with fifty pounds sulphate of ammonia, and sow it on the barley when two or three inches high. Cut before it is dead ripe. The crop is about fifty bushels or more per acre. The cost of plaster and sulphate of ammonia is about 16s 6d. In the fall let no beast feed on the young clover. Dress it with sixteen good loads of yard dung, and sow on the dung, after it is spread, 150 pounds plaster. The yard dung will be worth 3s 6d per load, besides spreading and carrying to the field. In spring sow two bushels ashes, forty-eight pounds of bones, 100 pounds salt, fifty pounds plaster, the cost, in all, being 13s 6d. There will be four tons (8000lb) of hay or more, as the fourth crop. After the second cutting do not let the after grass be eaten down. I cut as soon as the grass is in bloom, before seed is formed—last year I began on the 17th June. The cutting, curing, and drawing to the barn costs about 6s per ton.

The fifth crop is hay, top-dressed in spring with four bushels of ashes, eighty-four pounds, or more, burnt bones, 150 pounds salt, 300 pounds plaster, forty pounds sulphate of ammonia; 100 pounds sulphate ammonia would be better. The total cost will be £1 13s 6d per acre. The amount of hay will be about the same as last year.

The sixth crop, hay, dressed the same way; the crop will be the same. The seventh crop is pasture, dressed in spring with two bushels ashes, 100 pounds plaster, 100 pounds salt, 48 pounds burnt bones, in all amounting to 11s 9d. The eighth crop, pasture, dressed the same. There will be little gain, the rent being £1 2s, top dressing, 11s 9d, making £1 13s 9d. The improvement on a beast will not exceed £2 10s, which would be a balance of 17s 6d left, for interest, profit, and risk. Would it not be better to cut all the grass, and feed the cattle in sheds?

The ninth crop is hay, dressed in the fall or spring with eighteen loads yard manure, top-dressing with three bushels ashes, 150 pounds salt, eighty-four pounds bones, 300 pounds plaster, the total cost of top-dressing being £1 3s. The crop will be four tons, at least. Do not let the after grass be eaten off in the fall, but plough it down for oats. Top dress as before, and subsoil after the oat crop in the fall; it does not do so well in spring. The ground is full of every substance that a crop requires, and it pays its way, and leaves a balance every year. The clover will leave about four tons of roots and about a ton of leaves and stalks, besides the greater part of the manure given to the last crop of clover. I have no doubt that the enriching with clover is as good as improving with turnips, and cheaper.

Here follows an elaborate account of cost and profit, which we should have been very glad to have inserted, as it contains much valuable information, but after patient study we have not been able to reduce it into proper shape for publication. There are inaccuracies, and discrepancies, and ambiguities which pass our skill to rectify without the assistance of the writer. If he will furnish the information in a clearer manner we shall be glad to publish it. The chief feature in the report, as will be gathered from the preceding portion of the letter, is the large amount of manure which he applies, and the quantity of stock which he keeps, comprising, besides the working horses, 60 cows for dairy purposes, 7 stall-fed, 33 pigs, 75 sheep, 1 bull, and 18 young cattle. The sum of all the produce, consisting of surplus grain and hay, the sale or product, of sheep and pigs, and the cheese sold, amounted to £1611 2s 0d, or to resume the writers own account:—

Value of Produce after being manufactured	£1611	2s	0d
The improvement on 18 cattle and 620 loads manure	130	0s	0d
Total value of incomes	£1741	2s	0d
Cost of working the farm	1239	16s	0d
The balance will be	£501	6s	0d

There are many unforeseen losses, such as cattle dying, frosts and sickness, and the farmer's remuneration for his labours and risks must also be taken into account. I began this method of manuring four years ago. I have used ashes, bones and plaster, about twenty years, with recently some guano. I try to give, as near as possible, the substances contained in the ashes of the plants, less potash and more soda. My intention with so much plaster is to fix ammonia and supply lime and sulphuric acid. The hay and grain sold would feed over forty cattle, but I have not houses sufficient, although there are as many as would make a little village. As soon as cows calve, they are fed with good clover hay, cut into half-inch lengths, made damp with water, and grain broken fine strewed on the hay, with about twenty-five pounds of beets. In summer they have clover or cornstalks cut, twice daily, and when pastures are bad they are fed three times daily. I get from eight to ten tons of bones, burn them and grind them fine. The sulphate of ammonia is brought from England. I dissolved the bones for two years, but sulphuric acid got very high; in Montreal seven cents was wanted for it. I have used Snow's superphosphate, twenty barrels last year, and I have twenty barrels for this year. Vitriol can be got in England at 9s 6d per 112 pounds. For an acre of turnips or potatoes, 100 pounds burnt bones is taken, 50 pounds vitriol, 50 pounds water, and 50 pounds salt. The water is put in a pine tub with wooden hoops, add the vitriol, mix the bones, add the salt, stir; let it remain some hours. No ammonia is used except for top dressing. This is sufficient to raise twenty-five tons of turnips. The yard manure is put on the young grass, and great crops are the consequence.

JOHN ROBERTSON,
Bell's Corners, Ont.

March 18th, 1868.

War Against the Thistle.

To the Editor of THE CANADA FARMER:

SIR,—A short article, over my name, published in the first of the November numbers of 1867, seems to have given material for sharp criticism from "Publicola," on my practical way of exterminating that much dreaded enemy, the Canada Thistle. But that is what we desire; the more of it the better. The practice or theory that cannot stand the scrutiny should go down. Too many false systems and humbugs have been imposed upon the farmer already, who, in many instances, have squandered time and money to no purpose; such as cutting in the moon, and sundry other trash, which my friend has quite ably exploded.

But, has he succeeded so admirably in undermining my position? We shall see. He has not, in all his long letter, ventured to deny that frequent ploughing and cultivating, at the proper times, will destroy the existing thistle; but, on the contrary, most positively affirms it. I need but refer you to his own experience in his cultivation of the Mangold-Wurtzel patch, which he says was as perfect a bed of thistles as Canada can produce, which he exterminated in a single season; and the instance of the young farmer's potato patch, which he gives, are arguments most conclusive, and ought to convince the most sceptical of the success attending the method set forth in my letter.

He begins by counting the cost attending my method, which sums up, according to his rendering, to $8 per acre; and in the very next breath, rules me out of existence, on account, as he says, of fallowing being the most successful means of propagating the evil, by preparing the soil for the most favourable reception of the flying seed.

Perhaps he forgets, or does not know, that every farmer in this part of the country, at least, makes it a point to have a summer fallow every year, which he ploughs at least twice, and often three and four times, besides the cultivating and harrowing—not one or no thistles. Then, as "Publicola" would say, why not "strain a point," and plough and cultivate at the proper times to kill the thistle? So you may see, sir, that his objection, financially, just amounts to nothing.

And the point he labours to make on the adaptation of the fallow to receiving the floating seed, I shall neither affirm nor deny. It is enough to know that the fallow, worked as I have directed, is no better adapted for its reception than *any* ordinary fallow ground. Neither was I arguing a system of warfare upon an imaginary foe, but against one really existing. Our Legislature has introduced a system of prevention, which I think both practicable and sensible. Would that it were better observed. So, with this at my back, I think myself safe at this point.

The circumstance which he mentions of the slip planted in the spring, producing five and a half lbs. roots in the fall, with enough still remaining in the ground to send forth sixty plants in the spring, is quite sufficient to show that the increase from the root is much more to be dreaded than that from the seed; and it is reasonable to presume that not one of a million of seeds ever produces a plant. Those who have taken any notice of the spreading of the Canada Thistle, must know that it is effected principally by patches, extending their borders yearly, and also by careless cultivation, changing bits of roots to places previously free from the thistle. And thus, in a single year, hundreds of plants will mark another centre of action; to send forth its invading army, subduing the country to itself.

I have kept fields in meadow for a length of time, and have mowed twice in a season, though perhaps not sufficiently "straining a point," and in some instances thought the thistle subdued, but when ploughing the field some would make their appearance again. By following the plan which I recommended in my letter of November last, I have destroyed every thistle in three twelve acre fields, taken in rotation, in three successive years, my friend's "seed bed" to the contrary notwithstanding. I have tried a sod field since, but did not wholly succeed, as the cultivation was necessarily imperfect. I gave it, however, a double portion of clover seed, hoping to keep it at bay until I can give it another trial.

I have no doubt but the gentleman's system may be a successful one; and my own experience, as well as the many honorable testimonials which I could produce, must settle the fact in my mind at least, that the method I have set forth is both practicable and successful. I can only hope that every farmer who is infested with this common enemy may adopt some true system, and that a universal and unceasing war may be waged until this scourge shall be banished from our soil.

PETER SHISLER.

Sandy Land.

To the Editor of THE CANADA FARMER:

SIR,—Although farming is not my calling, I have been a subscriber to your journal since its first issue, and always have taken a deep interest in agricultural matters. It therefore affords me much pleasure to observe the improved system of agriculture pursued here, as well as the increasing intelligence of the farmers generally, and for these your valuable paper may justly claim some credit, for I find it constantly read by the leading farmers.

There has been a large influx of new blood to this county in the case of persons (generally of an intelligent and respectable class) who were compelled to leave their homesteads in older and wealthy townships, in consequence of the wheat failure, and seek a new home in our colder but more productive region. This influx indicates that the locality of Barrie and its back country has lost its ill repute for everything that was poor and miserable—a character, I dare say, you are aware it had about ten years ago, when it also had an unenviable notoriety for "sand." Yet it concerning a piece of this self-same sand that I particularly to consult you. I have a piece (four acres) of land or "sand" which I would prove for pasture, and do something to it if possible.

I thought of doing so about three months ago, I could have procured a good quantity of stable manure. This I would have top-dressed it with, and perhaps have ploughed down some of it, and sown clover. However, it is too late to collect manure now, and I have been advised to sow plaster (gypsum) over it on the sod. Do you think it would be of much use, and what is its *modus operandi*? I see Professor Liebig's theory is, that it fixes the ammonia of the atmosphere. If so, it would act equally on sand or clay soils.

There was a gentleman in this town some years ago, from a part of France where agriculture is made more of a science than it is here, and he held a theory and had a receipt principally composed of phosphate or super-phosphate of lime, ammonia, &c., and by which he said wheat or any kind of crops could be profitably grown on sand which had been deprived of every particle of organic matter by burning.

A CONSTANT READER.

Barrie.

NOTE BY ED. C. F.—We would recommend you to apply as much manure as you can possibly get to the land, and plant it with potatoes. Next spring plough in more manure, and sow clover thickly. After taking off a crop or two of this, plough it under. Raise a crop of grain, if you wish, and lay it down to pasture. Such land as yours requires the addition of materials for plant food, and this is best done by barn-yard manure, and especially by ploughing under green crops, such as clover. By repeatedly following this plan, the land may be made rich and productive. We believe the plaster will do more to stimulate the growth of a growing crop than permanently add to the productive resources of the soil. The Frenchman's experiment on a small scale has repeatedly been tried, and only proves that if you supply to sand or burnt clay, or any other pulverized medium, the materials of plant food, vegetation will take place in such soil.

Stock Department.

"Young Conqueror."

BEST DRAUGHT STALLION, OF ANY AGE, AT THE LAST PROVINCIAL EXHIBITION.

THE accompanying illustration is taken from a photograph of "Young Conqueror," the imported stallion owned by Mr. Simon Beattie, which obtained the diploma as the best draught stallion of any age, at the Provincial Exhibition of 1867, at Kingston. "Young Conqueror" was purchased from Alex. Gilrath, Croy, near Glasgow, and imported to Canada last fall by Mr. Simon Beattie, the present owner. He is a dark bay horse, five years old this spring. From his pedigree and performance, it will be seen he stands unrivalled or unsurpassed by any other draught horse in Canada, and was pronounced by good judges one of the best horses in either Scotland or England, last summer. Farmers should avail themselves of this valuable opportunity, and encourage such animals, and the enterprise of the proprietors in introducing them amongst us. This horse gained prizes—first at the show of the Royal Agricultural Society of England, at Plymouth, as a two year old in 1865; first prize at Peterboro'; first prize at Huntingdon; first prize at Ely, £30; prize from the Society of Strathendusk and Killearn, near Glasgow, last spring; the second prize at the show of the Highland and Agricultural Society, at Glasgow, last summer, where twenty first-prize horses showed in his class, the best in Scotland and England. Since his arrival in this country, he has gained, besides the diploma at Kingston, the first prize at the fall show at Markham, and the first prize this spring at Markham. "Young Conqueror" is no relation to any of the draught horses lately imported into Canada. This valuable horse is now standing, we are informed, in Markham. It is almost superfluous to add that we believe him to be a most important addition to our Canadian stock.

"YOUNG CONQUEROR," THE PROPERTY OF MR. SIMON BEATTIE.

Animal Life.

IN a series of articles just completed, the CANADA FARMER has briefly laid before its readers the leading facts and principles, so far as they are known, in regard to plant life, or vegetable physiology. It is now proposed to offer a similar sketch of the various vital processes exhibited in the animal kingdom. Nothing but the merest outline of these deeply interesting and important subjects can, of course, be given in a periodical of this description; and it may be objected that such an elementary form of instruction will only encumber these pages with commonplace truisms, and statements of facts with which every one now-a-days is acquainted. But although to you, intelligent and well-informed Reader, these facts and principles may be as familiar as household words, are they so among the larger class of working men and farmers? If you think so, put some elementary question in physiology to your neighbour, or ask the man who takes care of your horses what effect bleeding will be likely to produce on the system, or how the air becomes vitiated by breathing, and see what answer you will get. To those engaged in the care of stock, some little knowledge of the laws which regulate animal life can scarcely fail to be of service; and yet, with few exceptions, their ignorance on these points is as general as it is profound. A sort of "rule of Thumb" serves their purpose in ordinary cases, but it often leads them into grave error, and in any unusual emergency leaves them helpless. We hope that the proposed series of articles may, in some measure at least, rectify this blind, unreasoning practice.

Let us notice, in the outset, what are the elementary constituents of animal bodies. In plants we found that the essential elements were *carbon*, *oxygen*, and *hydrogen*. In addition to these a fourth element, *nitrogen*, enters into the composition of animal tissues. This element, it is true, occurs in many vegetable compounds, (necessarily so to render an exclusively vegetable diet fit nutriment for animals;) but it is always in those which approach the most nearly to animal products. These are the principal constituents; but as in plants, so in different animal substances, other elements are also found in anbordinate proportion, as, for instance, iron in the blood. These four, however, are present in nearly all, and constitute the largest part of all animal tissues.

The organized material from which all the rest of the animal fabric is derived, which perpetually builds it up and repairs its waste, is the blood, emphatically called "the life." It will be convenient, then, to begin with some account of this fluid.

If we examine a drop of fresh blood beneath the microscope, we shall find that it consists of a colourless fluid, in which are floating a number of bodies of a circular shape, known as "blood corpuscles." These are of two kinds, white and red, the latter being by far the most numerous. The colourless liquid is called the "*liquor sanguinis*," or fluid of the blood, and consists of a yellowish viscid liquid, named *serum*, holding in solution a substance known by the name of *fibrin*. It is composed principally of water, and about eight per cent. of *albumen*, a substance with which we are all familiar in the white of an egg. One of its most characteristic properties is that of being coagulated or rendered solid by heat, or by the action of an acid. It is this property which causes the "setting" of the white of an egg on boiling. It is this also which renders the serum of blood a useful clarifier in certain circumstances.

Fibrin cannot be distinguished chemically from albumen; but it possesses the property of spontaneous coagulation under certain conditions. Its congealing or forming a clot when it escapes from its ordinary channels, and especially when exposed to the air, is one most important natural means of stopping the effusion of blood. It is readily organized, and exuding from inflamed or wounded surfaces, is the prime agent in the processes of growth and healing.

When fresh blood is allowed to stand in any vessel for about ten minutes, a yellowish liquid is observed to separate, and the red matter gradually loses its fluidity and shrinks in volume, forming a "clot." The reason of this is, that the fibrin, on being taken from the body and exposed to the air, coagulates, and entangles, as it were, the blood corpuscles with it, and shrinking after becoming solid, diminishes the volume of the clot, and separates from the serum. If coagulation is delayed by cold or other causes, the red corpuscles, being heaviest, slowly sink; and when the fibrin begins to solidify a colourless layer is formed at the top. This, which is known as the *buffy coat*, is formed when the blood of persons sufferieg from inflammatory disease is allowed to coagulate, and is seen in the blood of horses even in a healthy condition.

The red corpuscles of the blood are flattened disks of a circular form in most mammalia, but in birds, reptiles, and fishes, oval. They are smallest in mammals, measuring in man $\frac{1}{3200}$ of an inch in diameter, and in the ox $\frac{1}{3200}$ of an inch. They are largest in reptiles, being $\frac{1}{1200}$ by $\frac{1}{2800}$ of an inch in the frog, $\frac{1}{250}$ of an inch in the Proteus. In the oval corpuscles of reptiles there is a central nucleus, but this does not appear to exist in the fully developed red corpuscles of mammalia, though their bioconcave shape gives to them in certain lights the appearance of possessing such a central opaque body. They are composed of two substances, of which one, *globulin*, contains sulphur, and the other, *hæmatin*, contains iron. It is the hæmatin that gives to blood its peculiar red colour.

The white corpuscles, before mentioned, are much less numerous than the red, and are less regular in shape. They appear to be in an imperfect state, a state of transition, and indeed may be regarded as immature red corpuscles.

In vertebrata the colour of the blood which flows from an artery is bright red; of that which flows from a vein, dark red. But in invertebrate animals it is almost always colourless, and in those exceptions in which the blood is red, as in some worms, the colour is in the liquor sanguinis, and not in the corpuscles. We almost unavoidably use terms, as for example, artery and vein, which perhaps the beginner does not understand, but we shall come to the explanation of them a little further on, in describing the circulation of the blood.

The following tables of the composition of the blood are given by Dr. Kirkes:

Average proportions of the principal constituents of the blood in 1000 parts.

Water	784
Red corpuscles	131
Albumen or Serum	70
Saline matters	6.03
Fatty and other matters	6.77
Fibrin	2.2

Elementary composition of the dried blood of the Ox:—

Carbon	57.9 per cent.
Hydrogen	7.1 "
Nitrogen	17.4 "
Oxygen	19.2 "
Ashes	4.4 "

And this is so nearly the composition of flesh, that we may express it by the same chemical formula. The chief office of the blood is to repair the waste of the tissues. Among its subordinate uses may be mentioned that of carrying oxygen, derived from the air, to all parts of the body, and of removing effete matter from the various tissues to situations where it can be thrown off.

Classification of Stallions.

To the Editor of the CANADA FARMER.

SIR,—Will you allow me a little space in your valuable paper for a few suggestions on the classification of stallions at the Provincial Exhibition, and also at the County and Township Shows.

Under the present plan, Stallions are divided into four classes, viz.:—Thorough-bred, Road or Carriage, General Purpose, and Heavy Draught. As regards Thorough-bred and Heavy Draught, I would make no alteration, but I would divide the Road or Carriage class into two, making firstly Road Stallions showing speed (though not to the exclusion of other points), suitable for getting general light driving horses. Secondly,—Carriage or Coach Stallions, horses of good size, bone, appearance and action, suitable for getting horses such as ought to be used in gentlemen's carriages and other purposes where a certain amount of weight is required, with action. I would make it compulsory that these two classes should be shown in harness, so that the public can really see for themselves, and not be imposed upon by all sorts of circus performances that should count for nothing. These four classes would then include every kind of horse wanted either for business or pleasure.

What is called "the General Purpose Stallion," I would drive out of Canada, root and branch; he is doing more harm to our breed of horses than can be estimated, and the reason is plain. Of all kinds of mongrels there is none greater than "the General Purpose Stallion;" he is a combination of all known breeds; and you see shown in this class mongrel Clydes, mongrel Coach Horses, and a mixture of everything. Consequently the Judges get confused, and take refuge in the biggest of the lot, and give him first prize.

Unfortunately, these horses are more numerous than any other class, and their services are to be had cheap, which is balm to the pocket of many Canadian farmers. But in this, as in many other cases, cheapness is poor economy.

SPECTATOR.

☞ HARDWOOD ASHES, rubbed in dry on the back of sheep or cattle, is an excellent exterminator of lice and vermin. Mix the same with oats or feed, and it is an excellent remedy for worms in colts or horses.

The *Farmer* (Scottish) says that a sow of the Essex breed, belonging to W. J. Beadel, Esq., who occupies Springfield Hall Farm, Chelmsford, had the extraordinary number of twenty-three young ones at a litter, twenty-one of which were born alive.

FASTENINGS FOR OX-BOWS.—Every one who has yoked a pair of oxen has experienced the difficulty of holding upone end of a heavy yoke while inserting the bow and keying it in. The labor is much lessened by attaching a spring snap or catch to the bow,

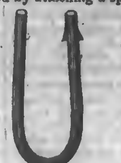


FIG. 1.

FIG. 2.

so that when simply thrust through the hole in the yoke (fig. 1) it fastens itself without any other attention. This is effected by inserting a large unannealed wire, so that it shall act on each side in a manner similar to the catch of an umbrella. A small iron plate with a hole in it as large as the bow, should be secured to the top of the yoke for these springs to rest upon.

Another mode of fastening the bow without employing a spring, is shown in fig. 2. A common butt or small door hinge is used for this purpose, and is screwed on to the top of the yoke, so that its movable part may cover about one-fourth or one-fifth of the hole. A notch is cut into the bow to correspond with this projecting edge of the hinge. On inserting the bow, this half of the hinge is thrust upwards, but drops and secures it as soon as it reaches the notch.

DISEASE AMONG DAIRY COWS.—The old disease, known as the "lung complaint" (*pleuro pneumonia*), which destroyed a large number of milch cows in the metropolis and suburbs, about ten or twelve years ago, has re-appeared in many of the cowsheds on the southern side of the Thames, and the dairymen have sustained very considerale loss by this epidemic.—*Pall Mall Gazette.*

Rural Architecture.

Useful Contrivances in Rural Economy.

WE have collected together, from various quarters, but chiefly from the *Illustrated Annual Register of Rural Affairs*, a number of useful hints on various matters, which, though not strictly pertaining to rural architecture, are yet closely allied to it, and will come better under that head than in any other department. Where not otherwise specified, it is to be understood that the useful little manual already named is credited for the following articles and illustrations:

FRAMING TO SECURE WIDE FLOORS IN BARNS.

WIDE floors, unobstructed by posts, are often a great convenience in barns, and as it is desirable to know a good way to frame a bent so as to dispense with posts and make it a self-supporting truss through

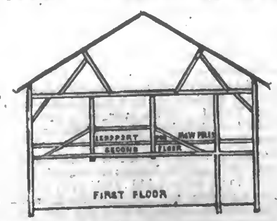

FIG. 1.

a part of its length, we have had the accompanying fig. 1, engraved. It represents a truss-bent in the barn of Rev. David R. Waller, of Bloomsbury, Pa., which supports the second floor of the barn, on one side, and a hay mow upon the other. The barn has two stories and a basement, and all the hay and grain is drawn in upon the second floor, over a bridge, from an approach walled and banked up. This truss is of simple construction, philosophically braced and entirely secure. The size of the timbers would vary with the width of the barn and the extent to which it is self-supporting, as well as with the weight it is expected to sustain.—*Country Gentleman.*

IRON GATE LATCH.—A correspondent in Talbot county, Md., sends the following description of an iron gate latch (fig. 2), which he has found cannot be opened by mischievous mules or horses. The straight portion is made by bending a rod double and welding the ends to a sharp point, which is driven into the gate post D. The latch C is of iron, and plays in the space between the sides of this straight piece. The cross-pin at B prevents the

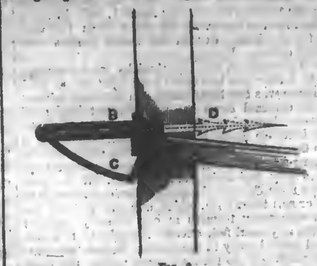

FIG. 2.

latch from flying entirely out, when the gate is shut forcibly. The gate is held shut by the pressure of the latch against cross-bar A, which may be a projection of the horizontal part of the gate, or a bar of oak, nailed or screwed to the stile.

SELF-SHUTTING GATE.—Various contrivances have been resorted to for causing gates to shut of their own accord. For small or light gates we have never found anything equal to the spring represented in the accompanying figure. One, which has been in use over ten years, appears to be as good as on the day it was put on. The different parts are shown more distinctly in fig. 4, where *a* represents a spring which is screwed on to the gate in a horizontal position as is shown in fig. 3, having a small wheel at its outer end, in which the bent lever *b* moves in opening and shutting. In the outer end of this lever a small chain is hooked, connecting with the gate. When opened, the spring is bent as shown by the dotted line. In constructing this contrivance, the great point is to form the curve in the lever, in such a manner that there shall be a continued and uniform pressure upon the spring, at whatever distance the gate is opened. The form represented will nearly accomplish this purpose, its length being about equal to the distance between the post and small wheel on the end of the spring. This contrivance was patented many years ago and retailed at $1.50, the spring and lever being simply made of steel red. The patent has probably long since expired.

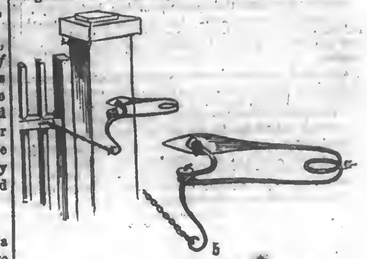

FIG. 3. FIG. 4.

The Dairy.

Dairy Farm, in Chester County, Pennsylvania.

ROBERT began farming four years ago, having about 100 acres of cleared land, for which he purchased twelve cows and two heifers. He engaged a farmer, who continued in charge two years, and made 1432 lbs. butter the first, and 1500 lbs. the second year.

This was principally from pasture alone, no provision having been made, by growing early rye, corn for fodder, or any other green food, to keep up a plentiful supply, either early or late in the season, when pasture is short, and it is so indispensable, in order to keep up the condition of the cows and their milk.

The third year the proprietor undertook the management himself, and made 2878 lbs. butter, and during the fourth year, ending April 1, 1867, he made 4055 lbs., having increased his stock from fourteen up to twenty head—five of the latter heifers with their first calves. He says:—

Now, I suppose, it will be asked by what management the butter was increased from 1432 lbs. to 4055 lbs. There was but little change in the stock, almost all of the original cows having been retained, and the increase being but three cows and three heifers; but the increase in the butter was from twice and a half to three times the quantity. The difference in the management was this: my original farmer kept the cows only, as I have before stated, on the pasture; the farm then had nothing grown expressly to fodder or soil them with, which was and is now the custom with many farmers in our country; neither was there any meal fed, except it might be to a cow that had calved early in the spring, before the pasture was sufficient to turn out upon; also, the cows were permitted to remain out, exposed to cold, wet storms (when they should have been stabled and kept warm and dry), thus early in the season checking the flow of milk, which is afterwards difficult to restore.

Early in the season the young grass, when cows are first turned out to pasture, is watery, and tends to make the cows scour very much; and although it will in that state increase the flow of milk, and also the quantity of butter, yet it will be at the expense of the condition of the cow, reducing her in flesh, and telling upon her during the whole season. At this time I consider it important that a cow should be fed with ship stuff or bran and cob meal, mixed, night and morning. This not only assists in preventing scouring, but by keeping up the condition of the stock, increases the quantity of the butter to a very considerable extent. My opinion is, that meal fed at this time pays better, certainly as well as at any other time during the season, not excepting midwinter.

I am well satisfied that the condition of the cow, in order to obtain from her a full yield, or one that will be profitable, must at all times be well looked to. She must be well wintered and fed, so that when she comes out of the barn-yard in the spring, after having calved, she is in good flesh, showing her keep and the care taken of her, and not like what is too much the custom of the country, viz., dry cows, wintered on straw, no shelter except the lee side of a barn-yard until the calf is dropped, when it is too late for the poor-in-flesh cow to yield her full capacity.

A cow should at all times, when milking, be fully supplied with meal; not stimulated to excess, however, for that would certainly produce reaction afterwards; but she must have a full and plentiful supply at all times of good food and water. For that purpose I have grown early rye to begin with in the early season, before the grass is sufficient to turn out on; then after harvest, during the dry weather, when the pasturage becomes short, Hungarian grass, to be followed with corn sowed in drills for fodder, which cut morning and evening, and fed to the stock whilst milking, fills them twice a day, and, with the pasture, makes up all that is required. During the last season, whilst it was necessary to soil with Hungarian grass and corn for fodder, we have also fed two quarts of ship stuff each night and morning, as we feel satisfied that, although the Hungarian grass and green corn will keep up the yield of milk, yet they will not alone make as much butter as a full supply of pasture or the natural grasses.

I look upon a cow as similar to a steam boiler; no matter how good they may be, unless the boiler is well supplied with water and good fuel, also well attended to, the supply of steam will be short, or it will be in proportion to the fuel and attention. So also with the cow; no matter how good she may be, if she is not well and plentifully fed and cared for, her product will be shortened.

Another very important matter with cows is that they should be protected from storms and bad weather. They should be fed and kept under shelter when the nights are wet and inclement; this more particularly in the early season, when the cow is fresh and in full milk; one exposure to a cold, wet night, has frequently reduced milk one-half. Also in the fall, when the nights become frosty, never let them remain out; be particular to stable them; and in the morning never turn them out on the pasture until the frost is melted off by the sun, as nothing, perhaps, dries a cow or reduces her milk more than eating grass with the frost on it. To many of these requirements the generality of farmers pay no attention whatever. In the early season, as soon as there is any pasture whatever, the cow is turned out of the barn-yard, to eat what she may find, and to remain day and night until the winter comes; there is also nothing grown or fed to eke out the scanty supply of pasturage that almost invariably occurs at some time in each season.—*Practical Farmer.*

How to Mak Gude Buter.

To the Editur of THE KANADY FARMER:

MAISTER EDITUR,—Havin been readin in your invaluable paper (from all sektions of the Kontry but this) how tha mak buter an greese, I wad jist gio u a bit inklin o tha way tha mak buter in our parts, an then you can gess abot the greese. In the fust place, tha don't stabel their kows, but feed em all winter on straw, an u ma expekt in tho spring like this, tha com out sae pur, that unles the sun is sinin vera brite, it will tak too of em to cast a shadoo. Tha are also covered with so long an shaggy hares, that when u are mylkin the pale is half full of hares. Aftr mylkin a boy an a dorg is sent wi em to the sumrfolor to pastr till evnin, when the boy an tho dorg is cent aftr em agin, an u ma xpekt tha com hom kanterin. Tha ar non so restles tha will not stand to be mylkd, for which tha git a gude hamrin. Tha are now klosd in the yard till mornin. Mean whyle, the mylk is removd to the darey, where it is sltrd thre a kulndr strainr, to tak out som of the hares. The dary is sumtims a gudo one, but in ten kases out of one it is a pur konstructd bildin, with shelf abov shelf, an plenty of holes for vntilaton—the upr story bein genraly occpyd by the poltry. Imeditly B.hind is the syne stye, in ordr to be konvenent for the sour milk; or it may be a log bildin, chinkd an plastrd, with a hole 5 feet deep inside. On this groun floor, tho mylk dishes is plasd; as thore is no vntilaton here, the mylk molds B-4 it sours. Aftr remainin in this state a konsidrabel tim, the kream is skimd in-2 a pork barrl, or othr vesel big onuf to hold it till a rany dae coms, when all the men is in. This tim havin arivd, the kream is put in-2 a churn, an worked for abot an our, without synes of buter. Hot water is now added in konsidrabel quantitys, when tho buter is on hand ito awa. It is now removd in-2 a tub or other vesel for the purpos, in ordr to get some of the butermylk out, after which it is saltd an mad in-2 roles for markt. A boy is now sent aftr the old mare, to tak it 2 the store, and bein redy 1 or 2 rols is put in eithr end of a grain bag, an put on the hoss, an the boy dispatchd with the instruktions to get hiest markt price, as it is new. Previous to the boy's takin it, I was requested to taste it, and give my opinion on it. This I done after some reluktanc, an said it was vera white and dry-lokin, but it was new. This was not near as great a eulogym as was expektet. Howsomever tha said it was mposible to mak yaller buter this tim o the yere. I axed em if tha ever red in the KANADY FARMUR how to mak buter. Tha said tha never took it, but Sam Miser says that Joe Novel says it is not xactly the thing, as it rekomends a nice ary dary with clean dishes, and tho kows well atendid-2. Bside the kows are to be well stabld, an kept in gude pastre. This a puer man can't allways afford, besids we allways get the hiest price for our buter here. My attension was arested by a nok at the doro, which provd to be a halker wanting to sell some mylk dishes. I now took my leave satisfyed with this style of kontry buter.

THERESA HUBB.

Veterinary Department.

Curb in Horses

THE affection known as curb is one of almost every-day occurrence, and it appears as an enlargement situated upon the lower and back part of the hock joint. This enlargement is the result of a sprain of a ligament that extends from near the point of the hock to the outer side of the small splint bone. The name applied to this ligament is the *calcaneo-cuboid*, or superior straight ligament of the hock. From the position of this ligament, and also from the strain put upon it, especially in hocks of a curby formation, it is very liable to be injured. Curb appears in many instances so very suddenly, that the common expression used regarding its appearance is, that the horse has "sprung a curb." When it first appears it is usually somewhat soft, and very hot and tender; the least pressure of the finger at once makes the horse jerk his leg upwards. It is very easily detected, especially if a side view of the leg is taken. In that position, a very slight curb can be readily noticed, and frequently there is lameness present, which in many cases is very severe, whilst in others it is only slight. A curb is a great eyesore, but it is rare that lameness from it proves of a permanent character, though frequently a callous enlargement will remain through life.

The causes of curb are various, as violent and sudden strains in galloping or leaping, or in being forcibly backed when attached to a heavily-laden waggon. It is also frequently produced by travelling in deep snow. This is a common cause in young unshod horses of three and four years old, who are often driven considerable distances without shoes; the hoof is worn down, and the horse slips at every step, thus throwing great stress upon that particular part. There are certain forms of limbs very liable to curb, as narrow hocks, and those in which the point of the hock (*os calcis*) is not well developed. Where this conformation is decided, the least violent exertion is very apt to produce a curb. This affection generally appears in young horses; it is rare that a horse of seven or eight years throws out a curb, without having shown signs of it in younger years.

The treatment of curb is generally attended with success. The horse should have rest, and a shoe applied with a high heel. By so doing the strain is taken off the hock to a great extent. Either cold or hot applications may be used with advantage, according to the state and extent of the injury. When the parts are much swollen and tender we prefer hot applications, as fomentations of hot water, afterwards applying flannel bandages, and a mild camphorated liniment. When the heat and swelling are removed, blisters are sometimes useful, and either the biniodide of mercury or cantharides have very good effect. At one time the firing iron was very often resorted to in the treatment of curb; but we are of opinion that it is only in exceptional cases where such a severe remedy is required. In slight cases, cold water and refrigerant applications will often succeed in allaying the tenderness, even without laying the horse off his usual work.

Veterinary Queries.

To the Editor of THE CANADA FARMER:

SIR,—I wish you, or some of your numerous correspondents, would answer the question, "What is the reason we have so many ringboned, spavined, and unshapely horses in this country?" If there is any remedy for the prevention of this evil, it is high time that farmers and others were made acquainted with it, that our stock of horses, instead of becoming poorer, may be improved.

Also, answer "What is the best method of shoeing a horse who is turned out in the front feet, to prevent it from interfering?"

Also, answer "What breed of horses is best adapted for agricultural purposes in Canada?" We have various breeds, as Clydes, Bloods, &c., all possessing different qualities. Would you recommend crossing the breeds, or keeping every kind distinct by themselves?

AN OLD CARTER.

Ringbone and other diseases of the osseous system, in many instances, can be traced to some hereditary predisposition. Diseased and worthless animals, when unfit for ordinary work, are frequently kept for breeding purposes, and the progeny commonly inherit those diseases which may have existed either in the sire or dam. We are of opinion that if greater care were bestowed in the selection of good, sound and vigorous animals for breeding, there would be fewer ringboned and spaviced animals to be seen.

To prevent interfering in a horse who is turned out in the front feet, the shoe should be applied to fit closely on the inside, and the nails applied around the toe and to the outside. In some instances a small piece of leather placed betwixt the sole and the shoe, and allowed to project outwards, has a very good effect in preventing interfering.

The last question is open to considerable discussion amongst practical and experienced men. At present we decline offering any opinion. Let our correspondents speak for themselves.

LOSS OF MANE AND TAIL.—The following is very useful in cases where there is a falling out of the hair of the mane and tail, viz.:—Glycerine, two ozs., sulphur, one oz., acetate of lead, two drachms, water, eight ounces. To be well mixed, and applied by means of a sponge.

SWOLLEN ABDOMEN.—A subscriber writes:—"I have a valuable mare now in foal to a blood horse, and about three weeks from foaling time she has become very much swollen all under her abdomen, and forward as far as her fore legs. I would not feel uneasy about her, only she had a foal three years ago, had the same swelling, and lost one teat in consequence. Can anything be done for her?"

Swelling under the abdomen is a common occurrence in mares previous to foaling, and is seldom productive of any harm. It is generally advisable, however, to give the mare gentle walking exercise daily, and every second night a teaspoonful of nitrate of potash, which may either be dissolved in water or given in a bran mash. This should be continued until four or five doses are given. She should also be sparingly fed for eight or ten days before foaling.

Poultry Yard.

Characteristics of various Breeds of Poultry.

A PAPER READ BEFORE THE ONTARIO POULTRY ASSOCIATION, BY THE PRESIDENT, A. M'CLEAN HOWARD, ESQ.

As President of the Poultry Association, I have often been asked the question, which are the best varieties of fowls to keep? My answer has been, it depends altogether upon what you more particularly want them for, and this must always be kept in mind in making a selection.

I will now give briefly the leading characteristics of the various kinds, for the information of intending breeders, leaving them to select accordingly. My remarks will be, as nearly as possible, the result of my own experience.

I will begin with the Cochins, as they generally head the list. They certainly are the largest, if not the best. I have not found them, under all circumstances, a profitable kind to keep for general purposes. They are not the best layers, nor do they lay an egg at all in proportion to their size. They are large feeders, poor foragers, inveterate sitters, but careless and clumsy with their eggs or chickens. They are very hardy, and when young, good for winter layers. The hens should not be kept over two years, as they then become lazy and good for nothing, and I pity the person who has to eat them at that age. In fact, I do not consider them first-rate for the table at any age, from their small proportion of breast meat. They are extremely docile, and from their kind and amiable disposition, are great favourites with some. They are very patient under confinement, and to parties having a small run or wishing to keep them out of their gardens, I consider them invaluable. I may say that I have found their chickens very easy to raise, and if hatched early attain a large size. I recollect hatching a brood of thirteen buff Cochins on St. Valentine's Day, a number of years ago, and raised nearly all of them. I kept them in a vacant horse-stall in my stable. I think, as a general rule, the coloured varieties are larger than the white, though Col. Hassard had some at the fall show which I think quite equalled their buff relatives.

I shall now proceed to the Brahma Pootra, and I think if I were keeping a large fowl, I should prefer them to the Cochins, as they are better foragers, not so indolent, lay well in winter, if kept in a tolerably warm place, are quite equal in size, and the chickens are very easy to raise. They are not the best summer layers, often wanting to sit all the time, and subject to the same drawback in that respect as the Cochins. They are not quite so patient in confinement as the Cochins. The light Brahmas especially, from their extreme depth of colour, their rich creamy white, and light pencilled hackle, are a particularly handsome bird.

The Dorkings next claim our attention. I cannot speak with so much positiveness in regard to them, never having had any. They are considered, *par excellence*, the English table fowl, though I believe it is questionable how far some of the French breeds have usurped their place in that respect. I think, in point of profit, the coloured Dorkings surpass their white cousins, being larger and more vigorous birds, though, to my taste, not to be compared with the white in beauty. I have always considered the distinctive features between Dorking and Barndoor fowls not sufficiently defined for them ever to become a fancy breed. I believe their chickens are rather difficult to raise. They are fair mothers, and tolerably good layers.

I will now proceed to the Spanish, a breed which, to judge from the large numbers of entries at our Poultry Shows, appear to be rather popular. There is no doubt that, as layers, they may be considered first-rate, laying large white-shelled eggs. I have found their chickens very easy to raise, the young cocks being exceedingly precocious. They are non-incubators, requiring other hens to hatch their eggs. They have, however, one very serious drawback; they are very apt to get frost-bitten, from the great size of their comb and wattles. The cold soon checks their laying. They also moult badly. Upon the whole, I think them better suited to a climate where the mercury does not get below zero. I am sure the owners of Spanish must feel the truth of my remarks, from the result of their experience, after the severe frost we had during the past winter. In fact, several have complained to me of the effect it had on their birds. There is a breed of White Spanish, having the same characteristics as the black, though I do not think they are as beautiful, as the contrast of the white face is not obtained in the white variety. It may not be out of place, as showing the length of time eggs will hatch, after the removal of the cock bird, to state that, a number of years ago, I had a very superior pair of Black Spanish; the cock bird having unfortunately died, I was desirous of saving all the eggs I could, and set eleven that were laid after the cock died. The first five hatched, the remainder were bad, but none of the chickens were strong.

The Games come next on our list, and I think that, take them all in all, nothing can surpass them. They are good layers of rich eggs, very hardy, which I think is a most important advantage, and from their great variety and extreme beauty, are general favorites. They are small feeders, and are, when in good health, always fit for the table, without extra feeding. The hens cannot be surpassed as sitters and mothers. Many think that, from their extreme pugnacity, they would be difficult to rear; but with ordinary care all that may be avoided; in fact, it is astonishing what order a good Game cock will keep in his yard. All the young stags are in dread of him, and in his presence are on their good behaviour.

I now come to the Polands. A great deal may be said in their favor; they are extremely hardy, and from the absence of comb are not so likely to be affected by the frost. They are good layers, but better in summer than winter, and are non-incubators. They are an extremely fancy bird, and like all the Spangled varieties, require great care in the breeding. I do not consider them so good for the farm as some other varieties, as they are more liable to be carried off by hawks, as well as to get their top-knots draggled and spoiled in the manure heaps of the barn-yard.

The different varieties of Hamburghs are special favorites of mine, as I consider that, in point of beauty and when well bred, they cannot be excelled. As layers they cannot be surpassed by any other variety. They do not lay quite so large an egg as the Spanish or Dorking, though I think the Spangled and Black are an exception; but they are more continuous layers of most delicious eggs. They are non-incubators, and persons keeping them will not be troubled with chickens unless they get other hens to hatch their eggs. They are rather impatient of confinement, the pencilled ones particularly. But to persons having a good-sized grass run, they are invaluable, as they nearly keep themselves. They are an extremely noisy bird, either singing or cackling all the time.

I am not aware that the Malays require any very particular description. I do not consider them at all a desirable breed to have in the poultry yard, as from their cruel and vindictive disposition, with their great size and strength, they are very apt to prove fatal in their encounters with smaller birds. I should recommend them chiefly as a cross, to get size and weight, not from any merit of their own.

The different varieties of French fowls, which have come into favor lately, require some notice. The principal varieties are the La Flèche, Houdan, and Crève Cœur, specimens of which were exhibited at the last fall show. Of the three kinds, the Houdan seems to find most favor in England, though I think I would prefer the La Flèche, as I think the damp climate of the Old Country, which is so much against them there, would not affect them here. My friend, Mr. Wood, a member of the Association, imported some from Paris a year or two ago, and I believe was very much pleased with them, having found them to be most excellent layers.

There are some few rules that are applicable to all varieties of fowls, without the observance of which it would be unfair to expect any useful results. If many eggs are expected, no hens should be kept, as a rule, after the second year, as after that the fecundity of the hen diminishes considerably. Hens require a certain amount of warmth in the winter, but not stove heat, which is bad.

I have erected a glass shed or house on the south point of my fowl-house, out of some old sashes, where the hens can come out and enjoy the fresh earth without getting in the snow. They have as much buckwheat and screenings as they can eat, plenty of warm straw, green food in the shape of cabbage, an occasional liver, cool ashes to bask and dust in, with a good supply of fresh water. Attention to these particulars has insured me a plentiful supply of fresh eggs during all the past winter.

Correspondence.

Township Societies.

To the Editor of THE CANADA FARMER:

SIR,—Having felt somewhat interested in the war of words that has been going on for some time past between the advocates of Township and County Societies, and some ideas occurring to my mind in connection therewith that appear to have been overlooked by our zealous friends, I venture to trespass on your valuable space for the purpose of making a few remarks on the subject. No reasonable person will for a moment pretend to deny that the country has been greatly benefited by our Agricultural Societies. That they have greatly contributed to our present prosperity as an agricultural country, must be evident to every one. They have awakened a spirit of enquiry and emulation in the breast of thousands, whose minds have become more enlightened as to the nature of their calling, and who have thus been stirred up to greater diligence in the prosecution of their business. They have done very much to elevate the calling of the farming community, not only in their own estimation, but also in the estimation of others, who were wont to look on the life of the farmer as one of constant toil and drudgery. They too have seen what wonders may be accomplished even in farming operations by the application of a limited amount of skill and capital, combined with industry and perseverance. Our agricultural exhibitions have enkindled in the hearts of many a feeling of honest pride and heartfelt satisfaction with their position in life, which should be felt by all who thus see gathered together the fruits of their luxurious fields, their richly laden orchards and their growing flocks and herds, while they have the happy assurance that with every returning season their substance is increasing, and that, with the blessing of Providence, they are above want and free from the fear of the fluctuations of merchandize or the embarrassments of trade. Doubtless but few will be inclined to dispute the fact of our having derived very great benefits from the existence of many of our Agricultural Societies, both Township and County. But while we admit all this, we may at the same time very properly enquire if all the good has been accomplished that might have been done. The above are, no doubt, very good reasons for keeping up our exhibitions to a certain extent. But is there not a possibility of carrying the thing too far? It is evident that a spirit of jealousy exists between the County and Township Societies; in some localities they are in direct opposition to each other. Now what is the cause of this, and where is the remedy for the evil? The cause of this opposition, it is clearly evident, arises from the holding of so many exhibitions; it is admitted by all that there are far too many. And if so, much valuable time and means are yearly expended that could be put to other purposes. It is doubtless a great mistake to suppose that all the good has been done that could be accomplished, when the annual revenue is given away by awarding prizes at shows. Much good might still be accomplished by introducing new kinds of seed, and thorough-bred stock, and encouraging a better system of farming; and here is a vast field of usefulness open to the Township Societies, which they can enter and work without coming in contact with the County Societies. In many parts of the country one show in a County would be quite sufficient. Especially is this the case in many of the newer sections of the country, where many small and weak societies have frittered away their means in the getting up of a few small paltry shows, where, perhaps, little or nothing could be shown worth the looking at; and after a few years the novelty of the thing has passed away, the people have become dissatisfied, and cease to take any interest in the affairs of the Society. To remedy this evil, our County friends proposed to swallow up a number of their weaker neighbours, or starve them gradually to death by curtailing the Government grant. This I believe to be a wrong policy. Would it not be better to assist and encourage the formation of Township Societies, and induce them to occupy a different field of operations from the County Societies? Let them expend their means in introducing new varieties of seeds and improved stock. The introduction of improved stock is evidently the proper work for a Township Agricultural Society, as it is not every neighbourhood that can boast of a private individual of sufficient means and liberality to engage in this expensive business. And again, many are willing to incur the first cost of purchasing a good animal, but they think it useless to commence improving unless they see their way clear to keep up their standard of excellence, and they are aware that to do so requires frequent renewals at a great expense. But when an Agricultural Society engages in this business, and purchases a number of animals, they have a great advantage over a private individual in their not being under the necessity of sacrificing an expensive animal after two or three years' service; by moving them from place to place as often as required, their services are retained by the Society for a number of years. We see among merchants, manufacturers, and in almost every other kind of business, the great advantage of combining the skill and capital of numbers in order to carry on more successfully the business in which they may be engaged. And why should farmers be indifferent to the advantage of acting on the same principle in the carrying on of their operations? In our Township Societies we have the machinery all complete, and in no possible way could it be used to better advantage than in improving the live stock in a township. In conclusion allow me to add, that much as the wealth and prosperity of any country may depend on its commerce and manufactures, still we must look to agriculture as the true source and foundation of all national progress.

JAMES LOVELL.

Brooke, Lambton Co.

Queries concerning the Agricultural Bill.

To the Editor of THE CANADA FARMER:

SIR,—May I ask to have a few questions answered through your columns? They refer to "An Act for the Encouragement of Agriculture, Horticulture, Arts, and Manufactures," passed by the Legislative Assembly of Ontario, with the name of the Hon. John Carling attached to it.

As a rule, I think that Acts of Parliament are worded very carefully, so that it is next to impossible for any one, with average intelligence, to mistake the meaning intended to be conveyed; but, in the Act referred to, I fear there is room at least for a doubt as to its intention, so far as regards Township Societies. For instance, Sec. 42 says that "A Township Agricultural Society may be organized in each Township in Ontario, in which there was not one already organized at the date of the passing of this Act, or in any two or more such Townships together, wherever a sufficient number of persons, not less than fifty, become members by signing a declaration," &c., &c. Now, I do not think it is clearly expressed by the above quotation, whether this section has any reference to Township Societies which were organized before the date of the passing of this Act; for the words "in which there was not one already organized at the date of the passing of this Act," may be intended to prevent a Society being organized at the same time, or in opposition to such existing Society.

I also wish to know if it is necessary in future that *all* Societies, whether old or new, shall have at least fifty members?

Section 46, Proviso No. 1, says:—"But no grant shall be made unless One Hundred Dollars be first subscribed and paid to the Treasurer of the County Society, and to the Treasurers of the Township Societies within its limits."

I should like to know if the Commissioner of Agriculture means that each Treasurer of the Township Societies must receive one hundred dollars, to entitle the County Society to receive the Government Grant, or does he mean that all the Treasurers of the Township Societies must receive, at least, one hundred dollars in the aggregate?

From Section 48, sub-section 3, it would appear that only new Members, having paid the Membership Subscription before the 1st of January, shall have the right of voting at the election of the office-bearers, and upon business applying solely to such year, as "all persons whose names are recorded on the books of any such Society, as legal members thereof, under this Act, shall have the right of voting on all *other questions* submitted to such annual meetings."

The above, in part recited section, does not tell me what I desire to know, which is—if it is necessary that any person, to be entitled to a vote at the annual meeting, must pay his subscription before the 1st of January, and if all members must so pay their subscriptions, or only new ones.

You will very much oblige me by answering these questions, for in a legal matter of this kind there should be no guess-work. I doubt not but there are some other backwoods Secretaries who will be glad to get a comprehensible version of this part of the Act.

A SECRETARY.

NOTE BY ED. C. F.—By the date of a private note accompanying the above communication, it would appear as though it had been sent some time since, but it has only now come into our hands.

In reference to the first enquiry, it is quite evident, and indeed is clearly expressed in sub-section 1, "That there shall not be more than one such Society in any Township." The section plainly declares that, if no Society already exists, one may be organized, under certain conditions. If such Society has already been established, it is recognized, and while it remains, another is inadmissible. With regard to the number of members mentioned in the conditions, it is meant, that *at the first organization* there must be at least fifty members. The provision does not affect the number of members of existing Societies, or of newly-formed ones subsequent to their organization.

In reference to Section 46, the meaning is—that the aggregate amount subscribed to the County and Township Societies must be at least $100, and not that any one Society must have that amount.

The interpretation of sub-section 3, in Section 48, seems also perfectly plain—namely, that to entitle any person, whether new member or old, to vote in the election of office-bearers, for the year next ensuing—that is to vote prospectively—he must pay his subscription in advance; but on all other matters, affecting the business of the past year, any member, legally recorded on the books, is entitled to a vote. No distinction is made in regard to old or new members.

We trust we have been sufficiently explicit to enable our correspondent, and others in like difficulties, to comprehend the scope of the provisions in question.

While on this subject, we take the opportunity of rectifying the number of the chapter which appears on the title page of most copies of the Act. This is set down as chapter twenty-three, but in consequence of a different arrangement having being made since the Act was printed, it now stands as chapter twenty-nine.

A Dilemma

To the Editor of THE CANADA FARMER:

SIR,—I am very much interested in the question of killing the Canada thistle. A recent writer on the subject, in your journal, has gone fully into the question; yet I think it is very hard for any man to come to a definite conclusion, when there is such flat contradiction. He says that summer fallowing is the best mode of propagating the Canada thistle. Now, if we turn to the CANADA FARMER of November 1st, 1866, page 322, we find an article, taken from the *Western Rural*, in which the writer says he had purchased twenty-seven acres of land, and twenty acres of it was in wheat, and nine loads of it was nearly all thistles. He summer fallowed it next year, and sowed it in wheat, and when he harvested it, you could bind all the thistles from the twenty acres in one bundle. Now, I should like to know what "Publicola" would make of that. The fact is, I have a farm of fifty acres rented, and it is entirely polluted with thistles and wild oats. I intended to summer fallow ten acres of it this summer; but since reading "Publicola's" letter, I have been puzzled what to do with it. I should be glad if he or any other correspondent would tell me what is the best thing I can do with it.

I would just remark that the people of Elma are getting more alarmed about these wild oats than they are about the thistles, and if any of your readers could give me, through the CANADA FARMER, any practicable way of killing these oats, they would be conferring a great favor on the people of Elma.

I would also state that I got one bushel of Mr. Membery's wheat, last spring, and I sowed it on about three-quarters of an acre of new land, where there had been potatoes twice. I ploughed and harrowed it as carefully as I could. It grew well, but did not produce an extra heavy crop. I had one hundred and fifty-one sheaves, and it turned out thirteen bushels of wheat. This is certainly the best wheat I have ever seen. I do not know where it came from, but a storekeeper in Listowel got a barrel of wheat two years ago, and sold it for ten cents a pound. They call it California wheat, but I could see no difference in the wheat.

EDWARD HAMMOND.

NOTE BY ED. C. F.—The best method of exterminating the thistle and other weeds is a question respecting which thoroughly practical men have given certainly very opposite opinions, probably in part from experimenting under different circumstances. We cannot presume to speak authoritatively on the subject, but as a general rule we believe that *clean seed* and *deep* and *thorough cultivation* will supplant any weed with a more useful crop. We have in our own experience succeeded in nearly eradicating the Canada thistle by summer fallowing, in a field so over-grown with the pest that much of the previous crop had not been harvested. In another year, had we remained on the farm, we believe the field would have been perfectly free. We, however, commenced the plan of smothering out the thistle with clover, thickly sown, as recommended by "Publicola."

Oil-Cake—Hedges—Winter Wheat.

To the Editor of THE CANADA FARMER:

SIR,—In a recent number of the CANADA FARMER you stated that you believed oil-cake is manufactured only in Montreal. I wish to inform you that T. J. Cottle, Esq., has been running his oil mill in Woodstock all winter, manufacturing a fine quality of raw and boiled oil, and, of course, oil-cake as well, which he sells at $30 per ton. Mr. Cottle has a very neat establishment—which includes a scutching mill. The press is a powerful hydraulic, and all the apparatus very complete.

I have been informed that there is a similar establishment at Berlin, I think, where the cake is sold at $25 per ton. This surely must be cheaper feed than either oats or peas at present prices.

Your Dunville correspondent, writing in the No. for April 1st, in reference to hedges, evidently is unacquainted with the true buckthorn, when he speaks of it resembling the hawthorn in blossom, only the berry being much larger. It must be the thorn that is common all over the country, and which has been tried as a hedge plant by a great many, and in some instances done well. The buckthorn is hardy and free from enemies—either insects or animals—but it lacks the prickles spoken of by your correspondent, and must rely principally on the strength of its branches for resistance, hence it requires longer time to make a fence than more prickly plants. I have hedges six or seven years old, and which will resist sheep only. Two years more, I think, will make it a tolerable fence. It inclines to thicken on the top, and all the pruning I can give it will not force the under shoots to strengthen. I planted thirty rods of the "hedge locust" last spring, but can only say of it that the foliage is beautiful in the summer season, and that it is as prickly as the osage orange. It is said that it will make an excellent fence in four years. So it was said of the white willow, but plenty of my neighbors have it three years old, and it is not yet strong enough to stand alone. It would not pay an agent to solicit orders for white willow cuttings here just now.

Any one wishing an ornamental as well as useful hedge, should plant the berberry. It has no faults that I am aware of, unless it is that it causes a blight to rest on grain crops in its immediate vicinity.

The hawthorn does not thrive well here. Mice are particularly fond of it. It is usually black with the bark louse, and does not thicken at the bottom as it does in England.

I have not seen, for many years at least, the winter wheat look as healthy and as little winter-killed as it is this spring. This has been a hard week for it, and may injure it yet.

R.W.S.

Woodstock, April 10th, 1868.

WHITE MELILOT.—Mr. John Manning enquires whether the seed of *Melilotus Alba*, recommended by Mr. Kirkwood, can be procured in Canada, &c. We do not suppose it is kept by Canadian Seedsmen, but they could, no doubt, procure it for Mr. Manning from England, with instructions as to the quantity of seed required per acre.

TARPAULIN FOR STACKS.—Can any of our readers reply to the following enquiry by a "Subscriber" from Goderich? "Will you inform me, through the medium of your paper, as to where tarpaulin stack cloths are manufactured, and also the name and address of the manufacturers. In the part of England where I lived, the covering used for large haystacks, during the building, was universally the large sail of a vessel. Would, therefore, thick sail-cloth be as advantageous as regards cost and durability?"

The Canada Farmer.

TORONTO, CANADA, MAY 15, 1868.

The Season.

WE are glad to be able to put it on record, that the favourable indications referred to in our article on "The Month," in last issue, still continue, and that, so far, the prospects of the Canadian farmer for the present year are such as to render all grumbling and misgiving utterly inexcusable. Rarely has there been in this country so unvarying and protracted a term of fine weather. Hence spring work has been pushed along with unusual celerity, and a large breadth of land put into crop. The weather has verged somewhat to the extreme of dryness, yet on the whole the seed has been well got in, and the fields that are up, have a very healthy look. Fall wheat never promised better; indeed we hear of very few cases of winter killing, and the only matter of regret is that the experience of the past few years has dictated caution and moderation in reference to this crop until it has come to be grown but sparingly. With so auspicious a season, it is a pity the area of land thus occupied is not multiplied a hundred-fold. Meadows look well, but would be no worse of more rain. With pleasant weather for work, the air has continued somewhat chilly, so as to retard the fruit buds. This, however, is no misfortune, as late blossoms are more likely to ripen than early ones.

Book Notices.

THE CANADA SHORT HORN HERD BOOK.—This goodly volume of 507 pages will supply a want long felt by Canadian stock-breeders. In 1854 a manuscript register of Shorn Horn Cattle was established by the Board of Agriculture, which has been of much service. Something more permanent and more generally accessible was needed, however, and is now furnished in the work under notice, which has been arranged and compiled after the model of the English and American Short Horn Herd Books, and is, we hope, only the first of a long series of similar publications, in which the *noblesse* of Canadian cattle will have their origin and histories perpetuated.

The rule on which pedigrees have been admitted into the volume, is the same as that adopted in connection with the English Herd Book, viz.: four crosses by Herd Book bulls. Every rule is liable to exception, and there are a few duly noticed, in the Canada as in the English Herd Book. It may be of service to some of our readers, if we quote from the preface the following table giving the amount of pure blood shown by any certain number of crosses.

"Suppose the original dam to be an animal without any Short Horn blood, and that she and her female descendants are bred to thorough-bred Short Horn bulls, the result of the successive crosses in the amount of pure blood obtained, will then be as follows:

1st cross gives	50	per cent	pure blood.
2nd "	75	"	"
3rd "	87.50	"	"
4th "	93.75	"	"
5th "	96.87	"	"
6th "	98.43	"	"
7th "	99.21	"	"
8th "	99.60	"	"
9th "	99.80	"	"
10th "	99.90	"	"
11th "	99.95	"	"
12th "	99.97½	"	"

"The result of the fourth cross thus shows 6.25 per cent., or 1-16th of the old blood of the original dam remaining, while the seventh cross exhibits about 1-100th, and the tenth about 1-1000th of the old blood."

Considering how easy it now is for farmers to get hold of females with a dash of Short Horn blood in them to begin with, it will be seen, from the above table, that there is very little excuse for breeding native cattle, and nothing but want of the spirit of improvement to prevent every farm-yard from having superior animals and a constantly advancing herd in it.

The Canada Herd Book is embellished with a number of lithographic portraits of distinguished Short Horn cattle, "the Duke of Northumberland," perhaps the best bull of the breed, take him for all in all, leading the way, and eighteen other noted bulls and cows following,—among them, of course, the Hon. D. Christie's justly celebrated Athelstane-ford females.

Of course it cannot be expected that we should go into a critical examination of such a volume. It would require a large amount of research to do that. We need only say of it further, that it bears marks of careful labour, and must have cost the compiler, Mr. Hugh Thomson, a large amount of painstaking and wearisome attention; that the typographical execution is very creditable to the firm (W. C. Chewett & Co.) by whom it was printed, and that our copy at least is well bound and lettered, so as to be quite ornamental on the book-shelf. We notice that the list of subscribers at the close of the volume is not very numerous, but we doubt not, that now the volume is out, it will command a wide sale. Every intelligent, progressive farmer in the land should have a copy.

AMERICAN CATTLE: THEIR HISTORY, BREEDING AND MANAGEMENT.—This is a book of some 500 pages, from the pen of Lewis F. Allen, of Black Rock, near Buffalo, N.Y., late President of the New York Agri-

cultural Society, Editor American Short Horn Herd Book, and author of some useful hand-books of rural industry. The object of the work, as stated by the author in his preface, "is not only to give a historical account of the Bovine race, to suggest to our farmers and cattle-breeders the best methods of their production and management, but to exalt and ennoble its pursuit to the dignity to which it is entitled in the various departments of American agriculture." From the little examination we have been able to give it, we cannot recommend it too highly. Every farmer should have a library, and this book well deserves a place in it. It appears to be rich in practical information about the breeding and care of cattle, and at the close gives the pith of "Lowson's Modern Farmer," one of the best works ever published on the diseases of cattle, and the best remedies for them.

TRANSACTIONS OF THE ILLINOIS STATE HORTICULTURAL SOCIETY, FOR 1867, pp. 283.

FIRST ANNUAL REPORT ON THE NOXIOUS INSECTS OF THE STATE OF ILLINOIS, pp. 103.

The two publications above named came to hand just as we were going to press with this number of the CANADA FARMER. We must therefore content ourselves with acknowledging the receipt of them, and postpone further notice until our next issue.

Act Respecting Cruelty to Animals.

WE have received a copy of a Bill introduced into the House of Commons by the Premier, Sir J. A. Macdonald, the humane object of which is to prevent cruelty to animals, which passed its second reading on the 17th ult., and will, we presume, shortly become law. It is needless to argue the necessity for such a Bill, while there are in the world so many brutes in human form, who have no flesh in their obdurate hearts. Generally it is of no use to reason with such persons, as they are impervious to everything but legal suasion. Perhaps the penalties of the Act in question lean to the side of mercy. A fine of not less than one, nor more than ten dollars, with costs, is lenient enough surely. The Act also gives considerable scope for cruelty in permitting sheep, lambs, calves or pigs, to be bound for conveyance to market a distance not exceeding fifteen miles from the owner's house or premises, such animals not to remain so bound longer than half an hour after their arrival at market. We are unable to see any necessity for binding at all. It is harsh treatment, that may easily be rendered unnecessary by having a crate, small frame, or light wiring upon the vehicle used for transportation. Fifteen miles with a heavy load and slow team implies four hours of painful endurance for the poor dumb creatures so bound. When a butcher goes out to collect animals for the slaughter, the time may be much longer, and the distance actually travelled much farther, because of the circuitous route taken in order to call here and there, though by the direct road it may not be more than fifteen miles from the owner's premises to market. We throughly approve of the principle and aim of the Bill, though we incline to think a little more stringency would improve it. While making a law on such a subject, it is desirable that there should be no wide meshes or large loop-holes through which barbarians may make their escape from the rod of justice.

PROTECTION OF SMALL BIRDS.—The Legislature of Quebec have passed a law for the protection of insectivorous birds, making it unlawful to destroy or capture any wild birds except birds of prey, wild pigeons, rice birds, kingfishers, crows and ravens, between the 1st of March and the 1st of August. For the true interest of agriculture, some similar provision should have been incorporated with the Game Law recently enacted in this province.

The New Patent Bill.

THE new Bill for granting patents is now issued, and provides, among other new features, that the Commissioner of Patents is to have a seal, and that he may mark out such rules and regulations and forms as are necessary. He is to report annually to Parliament.

The chief features of the Bill are as follows:—It provides that any person having been a resident of Canada for at least one year before his application, and having discovered what was not known or used by others before his invention thereof, and not being at the time of his application in public use or on sale in Canada, with his consent or allowance as the discoverer thereof, may, on application, obtain letters patent therefor. The patent may be granted to any person to whom the inventor has assigned or bequeathed. The petitioner for a patent is required to select his domicile at some known and specified place in Canada. Instead of the period of fourteen years in the present law, patents are to issue for five years, and be renewable twice, making the whole period fifteen years. The Government may use the patentee's invention for a reasonable compensation. Patents are to be null within three years, unless the manufacture of the invention shall have been commenced by the patentee in Canada. Patents in all the Provinces shall remain in force, as if this Act had not been passed. The fees are greatly increased under the Bill. At present they are $20 for fourteen years. By this Bill they are proposed to be $20 for each period of five years, or $60 in all. There is also an increase in the other fees charged. Intending applicant may file a caveat in order to cover an application for an invention which he has not yet perfected, which will be kept secret. The Commissioner has the power to repress a patent in certain cases. The applicant must be fully informed of the reasons therefor, and he may appeal to the Governor in Council. All documents are to be open to inspection by the public in the Patent Office. These are in the main the new features of the Bill. It is certainly an improvement on the present. Formerly, only British subjects resident in Canada could obtain a patent. Now, any inventor resident a year in Canada may do so. There is no clause extending patents in Nova Scotia or New Brunswick to the other Provinces, or the Dominion generally.

Dogs

SOCIETY is forbearing to a fault in reference to some of the burdens it carries, and endures without sign of complaint pretty severe exactions. We referred lately to the cost of the dog luxury (?) in a single Canadian township, which strikingly illustrated the truth of this observation, though it bore chiefly upon the amount of loss arising from sheep worrying. But the board of the creatures themselves, when they lead a harmless, innocent life, is no small item of national expenditure.

The March report of the United States Commissioner of Agriculture brings out some facts bearing on both these points. In 1866 *five hundred thousand sheep*, so far as reports were received, were killed by dogs in the United States, and their value was *two millions of dollars*. The number injured, so far as learned, was three hundred thousand, and the loss is estimated at six hundred thousand dollars. On the other point the Commissioner says:

"The cost of keeping dogs, most of them utterly worthless, when calculated for the whole country, assumes startling proportions. The estimate made in the report of 1863, of ten dollars per annum, or less than one cent per meal, cannot be considered extravagant, in view of prices paid for boarding dogs, the cost of keeping large numbers of them in cities, and their almost exclusive consumption of meat. As to their numbers, it is believed by many that they will nearly average one to each family, or about seven millions in the United States. In cities and towns that average would not be reached, while many a pack of hounds and assemblage of curs of low degree might be found in the ownership of single families. Ohio, with a half million of families, is supposed by many to have a half million of dogs; there are, however, little more than one-third of that number found on the assessor's books. It may be asserted, in view of all the data obtained, as a low estimate, that there are five millions of dogs in the United States, and that their subsistence involves an expenditure of fifty millions of dollars."

SALE OF PRIZE DURHAM BULL.—We learn that Mr. John Snell, of Edmonton, has sold to Mr. Wm. Collam, of Wilmot, the two-year old Short Horn Bull, "Loudon Duke," by Duke of Marlborough, 3866; dam, Mayflower 3rd by Airdrie, 2748. Loudon Duke was bred by Abraham Renick, Clark Co., Kentucky, and was winner of the first prize as a Yearling Bull at the last Provincial Fair.

Agricultural Intelligence.

Deep Cultivation at Yester

A FEW weeks ago the Marquis of Tweeddale, being Chairman of the Committee on Steam Cultivation, wrote a letter to the Directors of the Highland Society, offering to place a field at their disposal for the purpose of exhibiting the comparative merits of steam and horse-power in breaking up land which had hitherto not been ploughed above seven or eight inches deep. The Directors communicated with the various owners of steam ploughs; but these gentlemen, without exception, declined to send their machines. It then occurred to Lord Tweeddale that he might have in the same field a comparative trial of his ploughs, drawn by two, three, or four horses, with a view of testing the best way of applying horse-power, and also of the expense. The trial came off upon the 5th instant, when sixteen pairs of horses were divided as follows—one four-horse plough six ploughs with three horses, and five with two horses. The horses, as every one knows who has seen Lord Tweeddale's stock, are uncommonly well selected. The ploughs are well adapted for deep ploughing, and the men employed thoroughly acquainted with the work to be done. It would, therefore, be impossible to find horse-power more intelligently applied than at Yester. The field referred to is about a mile to the south-west of the village of Gifford, and is well adapted for a trial of ploughs, being comparatively free from stones, and there can be no doubt that the powerful steam apparatus of Mr. Fowler or others] would have broken it up effectively. It would, however, be very difficult to surpass the work made by the Tweeddale ploughs. The well-known Tweeddale four-horse plough, which has so long been worked at Yester, was at work nearest the road, turning a furrow fully fourteen inches deep, by fourteen inches wide, and the horses working easily.

The three horses yoked abreast were also working easily, turning a furrow of thirteen inches; while in the two-horse ploughs the horses seemed rather heavily strained. They turned a furrow twelve inches deep by twelve inches wide.

The field was visited during the day by several landlords and a number of practical farmers, who generally agreed that the three-horse yoke was the most economical of the three modes of applying the power.

Lord Tweeddale visited the field during the day, and all present were delighted to see the highly esteemed landlord and veteran agriculturist in such excellent health and spirits. A committee of farmers, having been asked by his lordship to inspect the field and the work done, drew up a report of a very satisfactory nature, in which they say:—

"An exact account of the time occupied in ploughing the field of twenty-five Imperial acres has been kept by Lord Tweeddale's overseer, and it is equivalent to fifty-four days of a pair of horses working eight hours a day. The Marquis of Tweeddale calculated that the actual cost of a pair of horses, including the ploughman's wages, is one shilling per hour. The expense of ploughing an imperial acre—thirteen inches deep—is therefore 17s 3d. We have to record our entire satisfaction with the work done, and of the great improvement effected by this deep stirring of the soil. The ploughs are exceedingly well adapted for the purpose, their peculiar construction allowing a deep furrow to be turned without bringing too great a quantity of the subsoil to the surface."—*Bell's Weekly Messenger.*

Preserved Meat from Australia.

WE are glad to draw attention to a new process which has been brought under our notice, and which we believe is about to be tried in South Australia. This process is the one which has been patented in New South Wales by Mr. Mort, who appears to be acting for the inventor, Mr. A. Morris. This gentleman, we find, issued a circular about twelve months ago, in which he stated that an experiment was about to be made for the preservation of meat by freezing without the use of ice, and without the meat being touched by any substance except the iron tank containing it. "Should this experiment," said the circular, "be successful, an economical plan will have been devised, by which the superabundant meat of the Australian Colonies can be introduced into the European and Asiatic markets in the same condition, both in regard to freshness and quality, as it is daily supplied in our own local markets." Ships can be fitted with the apparatus, by which, without injury to their capacity for carrying any other cargo, they can convey all over the world fresh meat for sale, or for the use of their crews and passengers during the voyages from and back to our ports, and without any risk of the meat spoiling." In order to show how this great advantage was to be gained, the circular proceeded to state that a model of the apparatus would be exhibited, containing a large quantity of fresh animal food,—meat, fish, poultry, &c., &c.,—and that the experiment would be submitted to the severest possible test. The investigation took place, and the result now is that we have a process in full operation by which meat—many hundred tons in one apparatus—can be easily frozen and kept in a state of refrigeration without losing its flavour and without becoming putrescent when thawed, as meat does when kept in ice, or frozen in the open air. In fact, meat preserved by this process, after having been kept for months, has been eaten at the table of the Governor of New South Wales, as well as in many private houses, without any one being able to distinguish it from similar food just obtained from the butcher's shop. This invention appears to be an application of Faraday's discovery of the liquefaction of certain gases by pressure, and the capacity of such gases for the absorption of heat on their release from liquefaction." The inventor, at all events, is convinced of the practicability of supplying the English market with fresh meat at a price far below the present rate, and with a view to this he has already left Sydney for the mother-country by the mail steamer. Mr. Mort has already patented the new process in the Australian Colonies, and additional protection is about to be obtained in France and England.—*Adelaide Observer.*

Ploughing Match.

A PLOUGHING match, under the auspices of the Township of Hamilton Agricultural Society, came off on the Farm of Mr. Jos. Hore, Camborne, on Wednesday, the 15th of April. The weather was very favourable, and a large number of spectators were present. There were twenty-two ploughs entered, all of which ploughed. The Judges were Messrs. W. Underwood, J. Mitchell, and — Russell. The following was their award.

CLASS NO. I.

1st prize,	Wm. Robinson	$10 00
2nd "	James Crawford	8 00
3rd "	James Raby	6 00
4th "	M. Smith	4 00
5th "	R. Defoe	2 00

CLASS NO. II.

1st prize,	William Mulholland, from Haldimand Township, a Spring Pump, presented by Jno. Lawless, of Baltimore, valued at	10 00
2nd "	Nicholas Doidge	8 00
3rd "	A. Ferguson	6 00
4th "	Thos. Aitchison	4 00

CLASS NO. III.

Boys under Eighteen Years of Age.

1st prize,	William Wright	8 00
2nd "	William Isaac	6 00
3rd "	James Davidson, a pair of Whippletrees and a Neck Yoke, presented by Geo. Hoog, Esq., of Baltimore, valued at	5 00
4th "	Samuel Berry, a pair of Bridles, presented by Mr. Thomas Haigh, of Baltimore, valued at	4 00

Agricultural Societies.

ADDINGTON.—In accordance with the new Agricultural Act, a public meeting, called by E. J. Hooper, M.P.P., was held at Harrowsmith on the 27th April, inst., to organize an Electoral Division Agricultural Society for Addington. The attendance was good, for the busy season of the year; about eighty persons were present.

It was Resolved, to adopt the By-Laws and Rules of the late Addington County Society.

The following gentlemen were elected as the office bearers for the present year, namely:—J. D. Ham, of Newburgh, President; Schuylor Shibley, of Portland, first vice do.; Wm. Laurence, of Loborough, second vice do.; J. B. Aylsworth, of Newburgh, Secretary-Treasurer. Directors for Portland, Samuel Stuart and Geo. Denison; for Loborough, Wm. Colwell and James Lahey; for Newburgh, R. F. Hope; for Camden, Miles Stormes and John Wager; for Sheffield, James Aylsworth and John Stuart. As Auditors, Douglas Hooper, of Newburgh, and Joseph Watson, of Harrowsmith.

Resolved—That a copy of the CANADA FARMER be furnished to each member who pays a subscription of one dollar and twenty-five cents.

NORTH RIDING OF OXFORD.—President, John Craig; vice do., John Dunlop and James Lockhart; Sec.-Treas., R. W. Sawtell. Directors.—Messrs. Parker, Buitch, Pepper, Towars, Ross, Williamson and Watt.

Nova Scotia Agricultural Exhibition

OUR friends in Nova Scotia are making preparations for a great Agricultural and Industrial Exhibition, to be held in the City of Halifax, during the second week in October, from the 5th to the 10th, inclusive. We have received copies of the prize list, which is very complete, and on a liberal scale, including all the departments and classes usually embraced in our own exhibitions. The Horticultural programme is especially full, and we notice again the energy and liberality of the Fruit Growers' Association, who have voted the sum of $200 towards the prize list in this department. Prizes are offered, not for the best winter, fall, cooking, or dessert apples, as with us, but for the best dozen of special varieties. The same classification is adopted with pears and grapes, and is, we think, a commendable feature in the arrangement.

The competition is restricted to Nova Scotia, except in the article of models for vessels, in which they challenge the world. We very cordially wish success to the undertaking, and we trust that the results will be so encouraging as to lead to an annual exhibition, and an extension of the competition in all the departments to the sister Provinces, and the United States.

☞ A Massachusetts farmer has paid $300 for a barrel of the Rose potatoes for seed. D. S. Henron, of Utica, N. Y., has sold a New Jersey farmer 125 bushels for $180 per bushel—or $10,000 for the lot.

☞ Strawberries, blackberries, and almost every kind of garden vegetables have commenced arriving in Chicago, from the Gulf of Mexico regions, *via* the Mobile and Ohio and the Illinois Central Railroads.

PRODUCTION OF BEETROOT SUGAR IN FRANCE.—The last return of the manufacture of beetroot sugar gives the total quantity produced, from the opening of the season on the 1st September down to the end of February, at 206,691 tons, or 2621 tons more than in the corresponding period of the previous year. The stock on hand on the 1st September being included, the quantity disposable was 228,261 tons. Of that total, 184,731 tons were taken for exportation, consumption, or distilleries, and the remainder was in the manufactories, either in a finished or unfinished state. The entrepots received, with the balance of last year's stock, 175,632 tons, and delivered 127,361. There consequently remained on hand over 48,000 tons.

CLIFFORD.—The inhabitants of Clifford have agreed for the construction of a steam grist mill. It is to be in running order by the first of November next. There is some talk of erecting a carding and woollen factory the ensuing summer.

MAPLE SUGAR.—According to the last United States census, about forty million pounds are made in the whole country, and one and a half million gallons of syrup. The New England States, New York, Michigan and Ohio, make the most. Nearly one-half of the whole quantity is made in New York and Vermont. The value of this production at the present market prices is not far from eight millions of dollars. There is no good reason why more system should not be introduced into the industry, and the business be generally extended. Why should not better varieties of the sugar maple be sought out and multiplied by nurserymen, and orchards be planted on a large scale? There is no danger of a glut in the sugar market, and if the product were multiplied ten-fold, the price would be still remunerative. The tree will flourish in elevated positions, and on rocky land quite too rough for tillage, and its cultivation requires very little care.—*American Agriculturist.*

EMIGRANTS FOR CANADA.—The *Pall Mall Gazette*, of the 16th April, says:—"About 150 emigrants from the East-end, including men, women, and children, will sail this morning from the Thames, in the screw steamer 'St. Lawrence,' bound for Quebec. The men, for the most part, are blacksmiths, fitters, sawyers and labourers, in the prime of life, with families of various ages. They go out to Canada at the sole expense of the East-end Emigration Committee; and they have been selected by a committee of gentlemen connected with the locality, including Mr Samuda, M.P.; Mr. Green, shipbuilder; Mr. Carrie, Mr. C. H. Wigram, Mr. Buttevant, and the Rev. J. F. Kitto, incumbent of St. Matthias, Poplar, among others. Towards this object Lord Overstone has handed over £800, the balance of the Herbert Emigration Relief Fund, set on foot for a kindred purpose some years ago, and the Mansion House Relief Committe recently contributed about £200, the balance remaining in their hands on closing their accounts. None of the emigrants who go out by the 'St. Lawrence' have been in the receipt of parochial relief at any time during the prevalent distress. On arriving at Quebec they will be put into communication with Mr. Stafford, the Government emigration agent there, who will make arrangements for sending them to parts of the country were labour is most in request. Each of them is furnished with a plentiful supply of suitable clothing, with provisions and books for the voyage, and, besides the assistance which the Government agent at Quebec is expected to render in forwarding them to their destination, a little allowance in money will be made to each family on arriving there."

FISH CULTURE IN ENGLAND.—The experiments successfully carried out at Huningue of course attracted the attention of every person connected with the great fisheries throughout Europe. The British proprietors and lessees of river fisheries at once began to make their own experiments, the largest and best known of which is that of Stormontfield, on the banks of the Tay. The method adopted is to capture the gravid fish, procure the ova by manipulation, and artificially impregnate by the addition of the milt, as they do in the French establishment. It is scarcely necessary to describe the egg-boxes in which the hatching process is carried on. They may be seen in the shop windows of several of the sporting newspapers—indeed, the artificial process of rearing fish from the ova has become quite a fashionable amusement, and is now familiar to most readers. Upwards of a million fish have already been passed on to the Tay, and a rise in the rental of the fishery of the river of ten per cent. has been the result. All the fish so reared were marked, and at an early period of the experiment it was found that forty fish out of every thousand had been so marked. One tenth of the fish taken in the Tay have been, it is asserted on the best authority, artificially reared at Stormontfield. Mr. Buest ("Peter of the Pools"), who manages the establishment, gives a very clear idea of the gain to the river by the artificial process of raising. He states that of the thirty thousand ova produced by the salmon in a natural state only five fish survive fit for the table. The same number of ova hatched in the establishment, and reared carefully in the pools, turns out eight hundred fish, and this number is a very low estimate.

The Vegetable Garden

To the Editor of THE CANADA FARMER:

SIR,—In making a few brief hints on the selection, preparation and cultivation of a vegetable garden, I would say to the person intending to prepare one, that the great secret of successful gardening is commencing well, and taking care that what is done is done thoroughly.

In choosing a place for a garden, select a gentle slope, towards the south if possible, and sheltered on the north side by bush or hills, but when there are none, it should be protected by a high and tight board fence or wall; when thus sheltered it will be several days earlier. The best soil for a garden is a sandy loam, but in the absence of this kind of soil from any place convenient to the residence, select the most suitable plot, and thoroughly *underdrain* it. Afterwards subsoil, or loosen the soil to the depth of two feet, without bringing any of the subsoil to the surface. Now haul some sandy loam to the garden, so as to cover it to the depth of five or six inches; if there is none on your farm, there is scarcely a place but what has some within a short distance. *Manuring* will be the next thing under consideration. If the soil is very light, ashes, well-rotted manure, and a little clay will effect a change; if heavy, ashes, manure, sand and lime will be beneficial, The *size* of the garden will depend upon the size of the family. It may be from one quarter to one half an acre; better too small than too large; for it is easy to make it larger if required, and there is nothing so unsightly as to see one end of a garden all grown over with grass and weeds. Now build a substantial *fence*, proof against garden thieves and fowls, for both of these classes are detrimental to gardening. All the time and money spent in the proper preparation of the soil is well spent; it is hardly possible to do too much in this way; it is the foundation of all after culture. It is like the foundation of a building; if an error has been made in this, it matters not how fine the superstructure may be, loss and disappointment will generally be the result. It does not cost much to put a small garden in good condition, while every dollar spent on its cultivation, when in bad order, is so much money wasted. But if put in good condition at first, it is both a pleasure and a profit to the owner. The *implements* necessary for garden culture are not very expensive. Only a few principal ones need be got at first, if expense is some consideration. A line will be found necessary, to lay out the garden walks and beds; a spade, a shovel, and a good hoe are indispensable, and these implements nearly every farmer has already. To draw drills, a drill-marker will be required, which every handy person can make; an iron tooth rake will be found necessary to finely pulverize and level the surface of the beds. A garden-trowel for transplanting, and a watering pot, made of good material, with a substantial wheel-barrow, are among the necessary implements for the garden. A necessary appendage for a garden is a *hot-bed*, so as to have vegetables early; for the majority of farmers do not reside near a professional gardener. A very good mode for constructing one will be found in the CANADA FARMER, vol. III, page 44. Also in the same volume, page 76, will be found a good plan for laying out a garden. No provision, however, is made in it for currants or gooseberries, but suitable places will readily suggest themselves to the reader, for these useful fruits. The biennial and perennial plants should have the warmest plots in the garden.

In the next place, the selection of pure and fresh *seed* will be found necessary to give good satisfaction to the cultivator. The *kind* and *quantity* of the different vegetables and fruits should be left to the taste of the families, but it is not best to attempt to raise too many varieties at first. The pleasure and profit in gardening does not consist in having a great variety, but in growing everything well; many in commencing gardens want to grow everything valuable or new. This causes great trouble, expense, and ends in little satisfaction. The best method is to begin with a few good, tried plants, and add to their number as circumstances require and experience increases. By all means keep trees out of the garden; this is one great error which most farmers fall into, so that in a few years the garden looks more like an orchard than what it is intended to be. A *manure-heap* should be kept in one corner of the garden, upon which throw all the weeds and rubbish of the garden, together with the slops of the house, and turn it over two or three times, when an excellent compost will be made. Declare a war of extermination with all *weeds*, and you will have full satisfaction for all your trouble.

CULTIVATEUR.

Ontario.

Transplanting Fruit Trees.

DRY weather the first year kills many thousands of newly transplanted trees. The condition of the weather and season cannot of course be avoided, but the trees can be put in a condition to stand a moderately dry season. Most persons, on receipt of trees, are in too great haste to plant them out; and particularly so if the trees have been received from a great distance. I myself used to think it necessary to put the trees into the ground as soon as received, but have found out by sad experience that this plan will not always work well. If they have been received from a short distance, and are perfectly *fresh*, then it will do to put them in the ground immediately; but if they have been long on the road and are much dried up, then they must be *restored* before planting. To restore trees, bury their roots in the ground with their tops in a leaning position near the ground, so that they can be shaded and watered conveniently. If they had started to grow when received, keep them in the ground until the whole leaves become a dark healthy green; or if they were dry, keep them in the ground until they commence to grow. If the trees have become very dry, it will be necessary to bury them entirely, root and branch, by putting them in a trench and covering them with earth that will touch every part of their roots and branches. They must be watered frequently, and should remain in this condition from a week to ten days. Trees that have become quite dry, may be perfectly restored when treated in this manner, and when transplanted will grow vigorously, while those that were not treated in this way will be very apt to die.

The *tops* of trees need moisture as well as the roots, and when they are exposed to the wind and sun, instead of receiving moisture, they are dried out and killed. When setting out the trees, dig the hole large enough to admit the roots without breaking or bending them. Spade the ground up loose at the bottom and leave the middle considerably higher than any other part. This will induce the roots to grow downward in their natural position, instead of forcing them to grow upward, as is sometimes the case when they have been crammed into a small hole. Place the tree about the same depth in the ground that it stood in the nursery, then fill all spaces underneath and cover the roots with fine earth *with the hands*, leaving no openings for the air, but completely covering and touching the roots firmly on every part. After filling the hole about half full, pour in a pail of water and give it time to settle before filling in any more dirt. When the hole is filled up, press the earth around the tree to support it in an upright position. Cover the fresh dirt around the tree with straw or litter to the depth of four or six inches, which will obviate the necessity of watering, unless the season should be an extremely dry one. The frequent waterings which many people give their newly transplanted trees are oftener an injury than a benefit to them. If the season be an extremely dry one, it will be necessary to water trees once in two or three weeks. This should be done by removing the straw and loose dirt at the top, and pouring on a pailful of water. After the water has settled, replace the dry dirt and straw as before. Do not leave the earth around the tree naked and exposed to the sun, for it will bake and frequently kill the tree. Watering the tops of the tree in the evening may be done as often as is convenient, with great advantage. It softens the bark and buds, and enables the tree to put forth its tender leaves directly. As to the time of planting trees, I will say that I have always had the best success with spring planting; although autumn planting has many advantages when trees are brought from a distance. But even in this case, I do not know but what it would be better to keep the trees over till spring and then plant them. Trees can be safely wintered in almost any climate by burying their roots in deep trenches. They should be placed in a leaning position, with their tops so near the ground that they may be covered with straw, corn stalks or leaves, to shelter them. Be careful and not cover the tops so closely as to smother them, for they require a small quantity of fresh air to keep them in a healthy condition.

If all these observations are heeded, in transplanting trees of any life at all, they will be almost certain to grow and do well.—*Wis. Farmer.*

The Nursery Business.

WE are glad to learn that the nurserymen have been doing a brisk business the present spring. The season has been an extremely favourable one for lifting and planting trees, and it is well that it has been so fully improved. It gives us especial pleasure to learn that a very large proportion of the orders filled have been from farmers, and that the good work of orchard and shrubbery planting is going on most satisfactorily in all parts of the country. When visiting the Toronto Nurseries, the other day, we were surprised and pleased to see what an extensive clearing out had been made by the spring demands. Mr. George Leslie, jun., assured us that had there been on hand three times the stock there was, it could have been readily sold, so thick and fast did the orders come in. This is, no doubt, owing partly to the well-earned reputation of the nurseries in question, but it is also an evidence and result of the growing interest in fruit culture and rural adornment, of which there are so many encouraging indications on every hand.

To make Cuttings Grow

A correspondent of the *Wisconsin Farmer* says:—"I used to have a great deal of trouble to make currant and gooseberry cuttings or slips grow, until I tried the following plan: I boiled some potatoes until they were nearly done, and then stuck one on each slip and put it in the ground. Every slip sprouted and grew very well all summer, with but one or two exceptions. The idea of putting the boiled potatoes to the end of the cuttings was to furnish and keep moisture enough for them to grow, until the roots became large enough to gather this moisture and substance from the soil. I never tried it on grape cuttings, but do not see any reason why it would not do as well with grapes as anything else."

APHIS BRUSH.—This very useful little implement was invented by the Rev. E. Bell of Colchester. It consists of two circular brushes, one inch in diameter, formed of very soft bristles, about three-quarters of an inch long. The handle is made of steel and is

elastic. Each leaf or shoot is brought between the two brushes, which are gently but firmly pressed together and drawn over the surface of the leaf, by which operation the aphides are removed without injury to the plant. It will be found very useful to those who keep plants in living rooms, or possess a small conservatory, but have no convenient means of subjecting their flowers and plants to fumigation with tobacco. The tediousness of the operation will, of course, prevent the use of the Aphis Brush on the large scale.—*Farmer* (Scottish).

Entomology.

Antennæ of Insects.

IN carefully examining the various parts and organs of insects, we are generally able, without much difficulty, to determine their special functions and properties; but there is one set of organs which has always been a puzzle to the student of natural history, viz., the *Antennæ*, or "Horns," as they are commonly termed. What is the real use of these appendages to the head, so universally found in all orders and kinds of insects, we are only able to guess at; what want of the insect they supply, or what sense they are the channels of, has not yet been ascertained with any degree of certainty. The difficulty is, that we and all animals whose functions and faculties resemble our own at all, and with which we are therefore better acquainted, have no organs that can be compared with these antennæ, or that resemble them in the least; we have thus no ground of analogy to go upon, but must base our views entirely upon the results of experiments. It is evident that they are used to a considerable extent as organs of feeling, and they have long been thought by many to be organs of hearing as well; at any rate the insect appears to employ them in deriving some sensations from the air as well as from surrounding objects, and in the case of ants we see them used apparently as organs of communication.

The late Dr. Clemens, in his valuable monograph on North American Sphingidæ (Hawk Moths) gives a detailed account of some experiments he made upon the antennæ of our largest Emperor Moth (*Samia Cecropia*). He states that he had long thought that the well-known habit of moths of spinning with their heads downwards, on any surface they chance to come in contact with, when they have singed their antennæ in a flame, was the mere expression of pain, and not caused by any loss of power of directing their movements; but that his experiments on these organs seemed to point to quite a different reason. He first tried the effect of cutting off the antennæ of a specimen that had just come out of its cocoon. When night approached, the insect having its wings then fully expanded, made no attempt to fly away, but remained quite docile, and permitted itself to be handled, without any desire to escape, or sense of danger. Upon being thrown into the air it seemed to have no control over its wings, but fell helplessly to the ground, and when forced at last to use its wings in flight, it appeared to be utterly unable to guide itself, and had completely lost all its usual power of hovering in the air. On other specimens, he made the experiment of cutting off only a portion of the antennæ at a time, and found that the more he cut off the less power the insect had over its wings, till at last, after finding itself quite unable to guide its flight, it ceased to employ its wings at all, and remained perfectly passive and helpless. From these experiments, he drew the inference that "the antennæ, instead of being the organs of any special sense, are in Lepidoptera instruments of atmospheric palpation, having especial reference to the action and use of the wings during flight." Of course, these experiments afford us no insight as to the uses of the antennæ of ants and other insects that are provided with these organs, even when destitute of wings.

But though we are unable to discover the exact objects and purposes for which insects are provided with these curious appendages, we yet cannot but admire their manifold beauties and wondrous variety of structure. Sometimes they are mere threads or bristles, at others they resemble saws, clubs, feathers, whips, strings of beads, spindles, combs, or even the leaves of a book; sometimes they are very long and composed of many joints, at others they are short and inconspicuous, with as few as only two joints. Some of the wood-boring beetles have antennæ five or six inches in length, with between twenty and thirty joints in each, and a little moth, about a quarter of an inch long, has them five times her own length. This long-horn moth (*Adela*) is thus described by Mr. Wood:—"It sits on a leaf, basking in the glaring sunbeams, while its antennæ, waving about in graceful curves, are only to be traced by the light that sparkles about them. They are as slender as the gossamer threads floating in the air, and, like them, only seen as lines of light. They are too delicate even for Queen Mab's chariot traces. The grey-coated gnat might use one of them as his whip; but it would only be for show, as becometh the whip of a state-coach; for it could not hurt the tiniest atomy ever harnessed. And yet the little Adela flies undauntedly among the trees, threading her way with perfect ease through the thickest foliage, her wondrous antennæ escaping all injury, and gleaming now and then, as a stray sunbeam touches them."

We have referred above to the apparent use of the antennæ as organs of communication in ants; Kirby and Spence thus describe their language, if it may be so termed, as expressed by these organs. "When the military ants go upon their expeditions, previously to setting off they touch each other on the trunk with their antennæ and forehead; this is the signal for marching, for as soon as any one has received it, he is immediately in motion. When they have any discovery to communicate, they strike with them those that they meet in a particularly impressive way. If a hungry ant wants to be fed, it touches with its two antennæ, moving them very rapidly, those of the individual from which it expects its meal."

The same authors quote Huber's experiments to show that these organs have the same use with bees. "He wished to ascertain how, when they had lost a queen (intelligence which traverses a whole hive in about an hour), they discovered the sad event. He first divided a hive by a grate, which kept the two portions about three or four lines apart; so that they could not come at each other, though scent would pass. In that part in which there was no queen, the bees were soon in great agitation; and as they did not discover her where she was confined, in a short time they began to construct royal cells, which quieted them. He next separated them by a partition through which they could pass their antennæ, but not their heads. In this case the bees all remained tranquil, neither intermitting the care of the brood, nor abandoning their other employments; nor did they begin any royal cell. The means they used to assure themselves that their queen was in their vicinity, and to communicate with her, was to pass their antennæ through the openings of the grate. An infinite number of these organs might be seen at once, as it were, inquiring in all directions; and the queen was observed answering these anxious inquiries of her subjects in the most marked manner; for she was all ways fastened by her feet to the grate, crossing her antennæ with those of the inquirers. Various other experiments, which are too long to relate, prove the importance of these organs, as the instruments of communicating with each other, as well as to direct the bee in all its proceedings."

The Earth-Worm.

WE have been applied to by Mr. Thomas Good, of Richmond, for some information respecting the common Earth-Worm. He desires to know "whether they are an injury to the soil, and if so, what would be the best way to banish them;" and he further states that "there are some fields in our neighbourhood polluted with them; one thing I know, they make the land very hard to plough."

We fear that Mr. Good has rather jumped at a conclusion. His land is hard to plough, and there are worms in it; therefore worms make the land hard to plough! Now, in reality, the very opposite is the case; instead of making the ground hard, the worms are doing their best to improve it. Their great office is to under-drain and till the ground, by burrowing through it in every direction, and thus loosening it and rendering it permeable by air and water; they do for the under soil what digging and ploughing do for the upper. In the first number of last year's volume of the CANADA FARMER (vol. IV, 1867, page 8), we gave an account of the earth-worm, and some of the benefits we derive from it; to which we beg to refer our correspondent. It is true that it is sometimes injurious in gardens from eating off, at night, young and tender vegetables; but it is admitted on all hands, that the good done by this animal to ploughed fields, pastures, and meadows, more than counterbalances any robberies it may commit in the garden, while even there it is of great use. We should be very sorry indeed to suggest any method for its destruction.

The Apiary.

Bees and Fruit Blossoms.

THE people of Wenham, (Mass.,) have voted, by a two-thirds majority, that no bees shall be kept in the town; they have judged that bee-keeping and fruit-raising are incompatible, and that bees are a nuisance. In reference to this subject the *Bee Journal* remarks:—

A silly prejudice against bees is entertained by some fruit-growers, based on the notion that the crops of fruit are injuriously affected, both in quality and quantity, by the visits of bees during the blossoming period. A more unfounded notion, or one deriving less support from observation and science, can scarcely be conceived. Yet it regularly looms up once or twice in a century, and creates as much alarm and consternation among the wiseacres, as the appearance of a comet used to do in by-gone days.

Repeated instances of the resuscitation of this prejudice are presented in the history of bee-culture in Germany, especially in the period between 1530 and 1800. On some of these occasions it was so widely prevalent and so rabid in its demonstrations, as to constrain the almost total abandonment of bee-culture in districts where fruit-raising bore sway. To the aid of this, came the substitution of cider and beer for the ancient mead or metheglin, as the popular beverage; and amid such opposition and discouragement, bee-culture rapidly sank to be of very subordinate interest, except in some favourable localities.

In 1774, Count Anthony, of Torrings-Seefield, in Bavaria, President of the Academy of Science at Munich, striving to re-introduce bee-culture on his patrimonial estate, found in this generally prevalent prejudice the chief obstacle to success. To overcome it he laboured assiduously to show that bees, far from being injurious, were directly beneficial in the fructification of blossoms—causing the fruit *to set* by conveying the fertilizing pollen from tree to tree and from flower to flower. He proved, moreover, by official family records, that a century earlier, when bees were kept by every tenant on the estate, fruit was abundant; whereas then, when only seven kept bees, and none of these had more than three colonies, fruit was scarcer than ever among his tenantry.

At the Apiarian General Convention, held at Stuttgard, in Wirtemburg, in September, 1858, the subject of honey-yielding crops being under discussion, the celebrated Pomologist, Professor Lucas, one of the directors of the Hohenheim Institute, alluding to the prejudice, went on to say:—"Of more importance, however, is an improved management of our fruit trees. Here the interests of the horticulturist and the bee-keeper combine and run parallel. A judicious pruning of our fruit-trees will cause them to blossom more freely and yield honey more plentifully. I would urge attention to this, on those particularly who are both fruit-growers and bee-keepers. A careful and observant bee-keeper at Potsdam, writes to me that *his trees yield decidedly larger crops since he has established an apiary in his orchard, and the annual product is now more certain and regular than before*, though his trees had always received due attention."

Some years ago, a wealthy lady in Germany established a green-house at considerable cost, and stocked it with a great variety of choice native and exotic fruit-trees, expecting in due time to have remunerating crops. Time passed, and annually there was a superabundance of blossoms with only very little fruit. Various plans were devised and adopted to bring the trees into bearing, but without success, till it was suggested that the blossoms needed fertilization, and that by means of bees the needed work could be effected. A hive of busy honey-gatherers was introduced next season; the remedy was effectual—there was no longer any difficulty in producing crops there. The bees distributed the pollen, and the *setting* of the fruit followed naturally.

The Household.

Yet a Little Sleep.

MEN in the present ago live fast. The amount of competition in every calling renders it necessary for almost every man to exert himself to the utmost to procure the very means of subsistence. Science, art, commerce; all the industries are feverishly busy; the Press teems with multitudinous productions, unapproached before in their variety, number, and the dispatch with which they are sent forth at least, if not always so sterling and solid as the works of former times; steam and electricity are enlisted in what may truly be called the race rather than the pilgrimage of life. And if, with all this fast living, the term of life is not shortened, it is because science has done her share in counteracting, in various ways, the exhausting tendencies of the age. The growing insight gained into the laws of health, together with the improvements in the healing art, have in a very marked degree diminished the mortality among children and young persons; while the comforts and conveniences of an advanced civilization have contributed not a little to mitigate the attendant evils of luxury on the one hand, and over-strained mental activity on the other. It may have been needful in the past to urge to industry and effort; it is now, we think, more frequently necessary to enjoin rest and relaxation. Amongst other things, in the matter indicated at the head of this article there is often serious misapprehension and error, amongst both the well-meaning and the selfish and inconsiderate, either in what they allow themselves, or what they exact from others.

Sleep is the most efficacious and most essential restorative for the wear and exhaustion of the system, produced by mental, nervous, or muscular excitement and activity. A due amount of sleep is just as important in the preservation of health, as a sufficient quantity of food. Indeed there are many cases in which a large modicum had better be abstracted from the daily meals, than an hour or two deducted from the period of slumber. Early rising is no doubt an excellent habit, but is not unfrequently too indiscriminately recommended. We have all seen or heard from zealous advocates of the practice, very ingenious calculations of the number of years a man may add to his life, as it is called, by an hour or two daily gained in the time of rising. Now, the calculation is often grievously at fault, and the very opposite of the assertion may sometimes be the true statement of the case. A man does not necessarily add to his life in any sense the hours which he takes from his nightly rest. He may shorten his days by thus prematurely exhausting his powers, and he may render his working ability, either of head or hand, less energetic and efficient while it lasts, in the vain attempt to violate Nature's laws, and curtail the season of repose and reparation. Within the limited scope of the writer's observation, this has been exemplified in more than one melancholy instance. One striking case in point especially presents itself, in the short career of a physician, a man of surprising energy and indomitable will, who made it a rule never to retire to rest before two or three o'clock in the morning, supplementing a hard day's professional work with literary labor (for he was a voluminous writer), yet always rising by seven to commence another day's routine of toil. This man's life seemed a perpetual battle against nature, who would often assert her claims in the most unmistakeable manner. In spite of all his efforts, he would drop asleep in the saddle, over his meals, and at other most inconvenient times and places. As might be expected, he was perpetually threatened with disease of the brain, and notwithstanding every care and precaution, except a proper amount of sleep, succumbed at length to the avenging malady. Sleeplessness, it is well known, is a common precursor, and occasionally the cause of mental derangement.

Admitting or passing over these general statements, it may be asked what is an explicit rule in the case? What amount of sleep does a man require? An eminent English divine used to express his opinion thus: five hours for a man, six for a woman, and seven for a *hog!* This may be a nice and terse way of laying down the law; but give us, nevertheless, the hog's allowance, if not a little more. No exact rule can be given, equally applicable to all. Differences of circumstance, age, temperament, and constitution, require, in this matter, to be taken into account, and vary the needful and healthy proportion between the hours of rest and activity—sleeping and waking. Generally the young require more sleep than the old, the man of active life more than the sedentary, the nervous, excitable temperament more than the phlegmatic. Nature, if only allowed fair play, will commonly prove the safest guide in each case.

We would strenuously advocate early retiring. Then early rising becomes easy and profitable. Late hours, whether devoted to pleasure or to work, are a violation of the laws of health, and cannot be indulged in with impunity. Let children especially go to bed early; they will spontaneously wake when they have had sufficient sleep, and it is cruel to rouse them sooner. Let masters be considerate in this matter; and if they wish their laborers to make an early start in the morning, be careful not to prolong the day's work unreasonably, or rob their dependents in any measure of a healthful amount of sleep. With a *slight modification*, we commend the Irishman's logic, who, after having indulged in an extra morning's snooze, and commencing his day's work in consequence later, made the circumstance a plea for leaving off earlier than usual, for it would never do, he said, to be late at both ends of the day. We may, at least, take a hint from Pat, and safely lay it down as a general rule, that it is not well to be late at either end of the day.

How to Act when the Clothes take Fire

THREE persons out of four would rush right up to the burning individual, and begin to paw with their hands without any definite aim. It is useless to tell the victim to do this or that, or call for water. In fact, it is generally best to say not a word, but seize a blanket from a bed, or a cloak, or any woollen fabric—if none is at hand, take any woollen material—hold the corners as far apart as you can, stretch them out higher than your head, and, running boldly to the person, make a motion of clasping in the arms, most about the shoulders. This instantly smothers the fire and saves the face. The next instant throw the unfortunate person on the floor. This is an additional safety to the face and breast, and any remnant of flame can be put out more leisurely. The next instant, immerse the burnt part in cold water, and all pain will cease with the rapidity of lightning. Next, get some common flour, remove from the water, and cover the burnt parts with an inch thickness of flour, if possible; put the patient to bed, and do all that is possible to soothe until the physician arrives. Let the flour remain until it falls off itself, when a beautiful new skin will be found. Unless the burns are deep, no other application is needed. The dry flour for burns is the most admirable remedy ever proposed, and the information ought to be imparted to all. The principle of its action is that, like the water, it causes instant and perfect relief from pain, by totally excluding the air from the injured parts. Spanish whiting and cold water, of a mushy consistency, are preferred by some. Dredge on the flour until no more will stick, and cover with cotton batting.—*Scientific American.*

BEWARE OF BENZINE.—From the facility with which it removes grease spots from fabrics, this substance has come to be regarded almost as a household indispensable. But few persons, however, realize the explosive character of benzine or the dangers attending the careless handling of the liquid. Being the most volatile and inflammable product resulting from the distillation of petroleum, it vaporizes with great rapidity, so that the contents of a four-ounce vial, if overturned, would render the air of a moderate-sized room highly explosive. The greatest care should be exercised in handling this substance, in proximity to fire, and it is important to remember that the vapor escaping from an uncorked bottle will cause a flame to leap over a space of several feet.—*The Scientific American.*

Hints to Housekeepers

HOW TO WASH GRAINING.—Take clear *warm* water, a clean, white cloth, and wash a small place and wipe dry with another *clean, white* cloth. Do not wet any more space than you can dry immediately with your cloth, as it must not be left to dry in the atmosphere; it must be rubbed dry, hence the necessity for clean white cloths. If the paint has been neglected until very much soiled with greasy fingers, or specked with a summer's growth of flies, a very little hard soap may be put in the first water, and then rinsed off with clean water; but avoid soap if you possibly can, as it dulls the varnish, however carefully used. On no account must it be rubbed on with a cloth.

WHITE PAINT.—As little soap as possible should be used with this, and that in the water and not on the cloth. It not only makes the paint yellow, but, after a little while, removes it altogether. A friend of mine, noted as a housekeeper, would never allow either soap or hot water to be used on paint, except in case of grease." Cold water and a scrubbing brush were her weapons of offence in waging warfare with dirt; but I should rather pay for painting once in a while, than expend as much strength and time as such a process requires. However, it gives a very fresh look to paint, and saves soap and fire if one is inclined to try it. For greasy spots I prefer a very little soda (carbonate), in the first water, to be immediately rinsed off and wiped dry.

FURNITURE.—Mahogany may be washed in very weak suds made of hard soap, and immediately rinsed and rubbed dry with a clean cloth. Some think water must never touch furniture, but once or twice a year; this method may be used to advantage. It makes the articles look as if newly varnished.

White spots made by heat on varnished furniture, may be removed by rubbing with a flannel cloth saturated with coal oil. I have often done so with perfect success. It is much easier than the old hot-paper plan. "R."—*Journal of Agriculture.*

Poetry.

Trees.

BY BENJAMIN GOUGH.

O ye tranquil trees, softly fanned by the breeze
As it languishes past,
Or swept by the wintery hurricane blast
In forests and woods, and wild solitudes,
Or standing alone,
Like sentinels, far in the desert, unknown.

When Adam and Eve trod the garden of God
On the flower-spangled glade,
Trees of Paradise spread in foliage and shade,
And in glory and light, on Lebanon's height,
Grand cedars of old
Grew and flourished, God's planting, for men to behold.

O ye beautiful trees, of thousand degrees
All over the world,
I sing to the praise of your beauties unfurled;
Where the dark Indian roves, or in clustering groves,
Fresh, verdant, and free,
Wherever we wander, we welcome a tree.

The wonderful Oak, when Creation awoke
From chaos and night,
Stretched out his broad arms to feel for the light;
A monarch art thou, with a crown on thy brow,
Thou glorious old Oak,
A king whose sceptre can never be broke.

And the Birch and the Beech, how beautiful each!
With Holly and Yew,
And Fir, in endless variety, now:
Tall Poplars in rows of Sabbath-repose,
And fruit-bearing trees,
By turns our sight and our senses to please.

O chorus of trees, stirred by tempest or breeze,
Break forth into songs,
Sweet chorales of joy from millions of tongues;
Every leaf has a tongue, God's praise to prolong,
The Giver of Good;
Clap your hands and rejoice, O ye trees of the wood!

O ye musical trees, sing your Song of Degrees,
To Dewn divine,
No minster has psalmody equal to thine;
Through the months of the year, your hymns fill the ear:
By day and by night,
God's beautiful trees in anthems unite.

Mark Lane Express.

Miscellaneous.

Little things in Farming.

THE whole success of a farmer hinges upon timely attention to little things. This, mainly, makes the difference between thrift and poverty. The philosophy of success is expressed in that old adage, "For want of a nail a shoe was lost, for want of a shoe a horse was lost, for want of a horse a man was lost." It is a little thing to keep accounts of the pecuniary transactions upon the farm. A half hour Saturday evening would enable most farmers to know just how they stand with the world. Yet, we suspect half of the men who cultivate the soil never make an entry in a book, and for want of this, the account runs up fearfully at the store, and many articles of luxury are purchased for which they are unable to pay at the end of the year. Debt accumulates, the farm is mortgaged, and finally lost, for want of a little paper and ink. It is a little thing to put up a tool in its place when not in use. Yet many have no tool-house, or place of shelter for any implement or vehicle. Things are left where they were last used, the plough in the field, the cart in the yard, the chains in the stable, the harness in the wood-house, the axe at the wood pile, and the rakes in the corn crib. Many do not even house the expensive implements they have bought, and reapers and thrashers are treated like old ploughs and harrows. The parts made of iron and steel grow rusty, and the wood decays. A machine that is good for thirty years with proper care is used up in five by abuse. It is a very little thing to turn a nut when it is loose; yet for want of the tightening the nut is lost, the bolt comes out, and the loaded waggon breaks down on the way to market, and a whole day for man and team is lost. It is a little thing to keep a horse properly groomed; yet for want of clean setlocks the skin cracks and the horse is lame, and the owner loses the use of him for months or weeks. Ventilation is a small affair; yet for want of it the health of stock in stables suffers severely, and disease sets in. It is a small affair to provide good seed at the beginning of the year, but the whole success of the season depends upon it. It is an easy thing to deal fairly with your neighbors and make a name that is better than "precious ointment." Many cheat on small occasions, do not deliver what they sell, and get a reputation for meanness that stands in the way of their success.—*American Agriculturist.*

Filing Saws.

In the first place you should be careful in selecting your saw at the hardware store. If you see one with the teeth standing straight out at right angles with the edge of the blade, or nearly so, hands off from that one; it will cut as well one way as the other, and not very fast either way. Look for one with the teeth considerably raking, that is, pointing downward; not too much, however. The lower edge of the teeth should not be at right angles with the blade, like a mill or hand-saw, but about half-way between that and the large cross-cut saw. See also that the line of the edge is straight or rounding, not hollowing.

Then file the teeth quite bevelling, carrying the file nearly at an angle of forty-five degrees from the blade. This will give a sharp, chisel-like edge to the teeth, longest at the extreme outer edge, which will thus go a little ahead and sever the fibres of the wood, and leave the balance of the end of the tooth nothing to do but clean out the chips of the kerf. In filing, keep the filed edge of the tooth straight—not round it off towards the point—and carry the file level, keeping the hand well up so that you think it is a little more than level.

A saw thus filed will need but little set, and in that little the teeth should be kept straight on their sides two-thirds of the way from the point to the base, and not turned short out just at the point. If one side is set out more than the other, the saw will run from a straight cut towards that side. If the teeth are filed shorter on one side than on the other, it will run in the opposite direction. In filing, you should bear the file hardest against the teeth on the side toward you, or it will cut the opposite side most, and make the teeth the smallest on that side.

A hand-saw should not have quite as much rake as a bucksaw, the object being smoothness rather than rapidity in cutting. In other respects, the same rules will apply.

A slitting saw, that is, one for sawing lengthwise of the grain, should have the lower edge of the teeth stand at right angles with the blade, with a light set, and filed nearly square, beveled just enough to leave the outer corner a trifle the longest. In buying a saw file, never buy the lowest priced. One that costs twenty cents is worth four ten cent ones.—*Wisconsin Farmer.*

Punch advises farmers to sow their P's, keep their U's warm, hive their B's, shoot their J's, feed their N's, look after their potatoes' I's, and take their E's.

☞ House rents are so exorbitant in New Orleans, that a "grasping landlord" advertises to let a splendid hogshead, just vacated by the former occupant, who leaves it for no fault. The premises are a sweet location for a family with young children, are in thorough repair, with bunghole centrally situated, and hoops in good order.

A CHEERFUL VIEW OF THINGS.—"How dismal you look!" said a bucket to its companion, as they were going to the well. "Ah," replied the other, "I was reflecting on the uselessness of our being filled; for let us go away ever so full, we always come back empty." "Dear me! how strange to look at it in that way!" said the other bucket. "Now, I enjoy the thought that, however empty we come, we always go away full. Only look at it in that light and you'll be as cheerful as I am."—*The Moralist.*

AVARICE OUTWITTED.—The following case is reported as having been decided in one of the courts of law. A wealthy man died, leaving the singular will that his executors should have the use of his property until his son, then a young man, should come of age, and that then they should give him such a portion *as should please them*, having full confidence in their friendship. When the time came the greedy executors assigned him one-tenth of the estate, and kept the rest. The young man, being naturally dissatisfied, brought a suit against them, a trial was had, and the judge decided that he should have the nine-tenths, and the executors the one-tenth, on the ground that they had shown by their conduct that the nine-tenths *pleased them.*—*American Agriculturist.*

SELF-POSSESSION IN A DIFFICULT SITUATION.—On Friday, 8th inst., as Mr R. Skead, jun., was riding on horseback over Sapper's Bridge, Ottawa, his bridle suddenly broke, and the horse taking alarm at the accident, dashed away at full gallop, whilst the rider was apparently without the means of guiding or checking his course. The accident was observed by a large number of persons, who all became alarmed for the consequences; as quick as thought, however, the young gentleman leaned over the horse's neck, got his hand into his mouth, seized his tongue, and brought him to before he had got two hundred yards from the spot where the bridle broke. This splendid feat, says the *Times*, elicited the admiration of all who beheld it.

Advertisements.

"RURIC,"

BY IMPORTED "SOVEREIGN," DAM "LEVITY," BY IMP. "TRUSTEE."

THIS Thorough-bred STALLION and RACE HORSE will stand at his Stables, on "The Hamilton Riding and Driving Park," two miles East of the City of Hamilton.

In 1864, RURIO was purchased by Col. T. G. Saunders, from R. Aitchison Alexander, Esq., the celebrated stock breeder of Kentucky, and brought to Canada in the summer of 1865, and is now owned by R. R. Waddell.

To encourage the breeding of good horses, the Terms will be as low as $10 for the season, payable at first service.

HUGH McLACHLIN, GROOM.

TRADE MARK.

R. J. FULLWOOD & Co.'s

(Late R. J. Fullwood & Bland's)

HIGHLY CELEBRATED

EXTRACT OF ANNATTO

FOR COLOURING CHEESE AND BUTTER.

THE superiority of this truly excellent, pure, and unadulterated Annatto, consists in its producing in Cheese and Butter, that rich, permanent bright golden cowslip tint colour, so much desired by all Cheese and Butter Factors; and the great celebrity and increasing demand has induced Messrs. R. J. F. & Co. to protect the consumers from fraud, by stamping all their preparations with their Trade Mark, as above—A Stag with Olive Branch,—to counterfeit which is felony.

IN COLOURING BUTTER it will be found by far superior and much cheaper than any other article in use for that purpose, and their Cake Annatto has stood unrivalled for the last 80 years.

ANNATTO WORKS,

SOMERSET PLACE, HOXTON, LONDON,

Established 1785.

*** Sold throughout England and the Colonies, by Chemists and Druggists, but see you get "R. J. Fullwood's," with a Stag.

Markets.

Toronto Markets.

"CANADA FARMER" Office, May 14th, 1868.

There has been rather more doing recently in produce; the market, however, is still very quiet. The sales taking place are principally on private terms.

FLOUR AND GRAIN.

Flour—The market has been very dull. At the date of our last report $7 15 was the price ruling for No. 1 superfine; to-day, however, $7 10 was accepted for 500 barrels of a good brand of No. 1 superfine.

Wheat—There is rather a better demand since our last report. Within the last few days the demand has improved, and several large lots changed hands at fair prices. Yesterday, 10,000 bushels changed hands, and to-day about 15,000 bushels. The sales were principally of midge-proof and golden drop, which sold in large lots at $1 70 for midge-proof and golden drop. In fall wheat there has been nothing doing. On the street market there has been very little doing. The prices paid were $1 65 for spring, and $1 80 for fall.

Oats—The market has been firm. Yesterday a lot sold at 54c, and to-day 1 car changed hands at 55c, in bags. On the street market from 58c to 60c is paid, the same prices ruling for retail lots.

Barley—The market has been very quiet. No sales except retail lots took place since our last review. Quotations nominally unchanged.

Peas—During the week the market was firm, with an advancing tendency; to-day, however, owing to an advance in Atlantic freights, buyers reduced their bids. Sales were made during the week at 91c; to-day lots were offering at 91c, with no buyers at over 90c. On the street market a few loads sold to-day at 88c.

Hay—Per ton, $15 to $21.

Straw—Per ton, $10 to $13.

PROVISIONS.

Butter—A consumptive demand only. Tub, per lb., 16 to 20c. Rolls, 22 to 25c.

Cheese—New, 10¼ to 11¼c.

Pork—Prime Mess per bbl., $16 to $17.

Bacon—$9 to $10 50.

Eggs—Packed, 10 to 12c; retail, 12 to 13c.

Potatoes—There is a fair supply. The current rates are 65c to 70c. per bushel by the load, and 90c. to $1 00 per bushel by the bag.

Apples.—The market is advancing as the fruit becomes scarcer. For choice samples as high as $3 would now be paid. Dried apples dull at $1 25 to $1 50.

CATTLE MARKET.

The market has been firm for first-class cattle; the supply, however, has not been equal to the demand. We quote per 100 lbs. dressed weight: 1st class, $8 00; 2nd do. $7 00; 3rd do. $6 00. There has been a good supply of 2nd and 3rd class cattle, but few 1st class. The late Guelph and Elora fairs were attended by a good many buyers from Montreal, Toronto, and Quebec; a few American buyers also being present. About 15 car loads of cattle changed hands at from 5c to 6c per lb. live weight.

Sheep of all kinds have been in good demand. We quote:—1st class $7 00 each; 2nd class $6 00 each; 3rd class $5 00 each.

Lambs have been in better supply, and are lower. We quote:—1st class $2 50; 2nd do. $2 00; 3rd do. $1 50.

Calves: 1st class, none offering; would bring $8 00 to $10 00; 2nd and 3rd class—market perfectly glutted; bring only from $1 50 to $4 00.

Hamilton Markets, May 12.—*Fall Wheat*, per bushel $1 62 to $1 72; *spring wheat* per bushel $1 55 to $1 62; *barley* do., $1 35 to $1 40; *oats* do., 60c to 65c; *peas* do., 85c to 90c; *corn* do., 65c to 70c; *potatoes*, per bag, $1 25 to $1 50.

London Markets.—*Grain*—Fall wheat per bushel, $1 60 to $1 66; spring wheat $1 50 to $1 55; barley $1; peas 80c to 82c; oats 43c to 44c.—*Hay*, per ton $8 to $10; straw per load $3 to $4; *potatoes*, per bushel, by load 60c to 70c; *carrots*, do. 25c.

Montreal Markets. May 13.—*Flour*—Superior extra, $8 to $8 25; extra $7 80 to $7 90; fancy $7 60 to $7 70; Welland Canal superfine $7 25 to $7 50; Superfine No. 1 Canada wheat, $7 30 to $7 45; superfine No. 1 Western wheat $7 25 to $7 50; superfine No. 2 Western wheat, $7 05 to $7 10; bag flour per 100 lbs, $3 50 to $3 60.—*Wheat*—Canada Fall, none; Spring, $1 72½ to $1 75; Western $1 66 to $1 70.—*Oats*—Per 32 lbs 47c to 48c.—*Barley*—Per 48 lbs $1 10 to $1 15.—*Peas*, 87c to 88c.

Chicago Markets, May 13.—Wm. Young and Co.'s report.—*Wheat*—Receipts, 21,000 bushels; shipments, 53,000 bushels. No. 2 firm at $2 11¼.—*Corn* firm at 66c; receipts 115,000 bushels; shipments 94,000 bushels.—*Pork* dull at $23.

Galt Markets, May 12.—*Flour*—Spring wheat $4; fall wheat $4 50. *Grain*—Fall wheat $1 63 to $1 73; amber wheat $1 60 to $1 63; spring wheat $1 58 to $1 62; barley 55c to 90c; oats 55c; peas 80c to 85c. *Seeds*—Clover seed $4 to $4 50; timothy seed $2 to $2 50. *Hay*—$10 to $15. *Butter*—16 to 18c. *Eggs*—9 to 11c. *Hides*—$6 to $7. *Sheepskins*—70c. *Wood*—$3 50 to $4. *Potatoes*—70c to 80c. *Pork*—Per 100 lbs., $5 to $5 50.

Guelph Markets, May 12.—*Fall Wheat*—Per bushel, $1 75 to $1 80. *Spring Wheat*—$1 60 to $1 64. *Oats*—56c. *Peas*—80c to 85c. *Barley*—$1 20 to $1 25. *Hides*—Per 100 lbs. $6. *Beef*—do., $7 to $8. *Pork*—do., $5 to $6 06. *Straw*—$3 to $4 per load. *Hay*—$9 to $11 per ton. *Eggs*—10c to 11c per doz. *Butter*—13 to 14c per lb. *Apples*—Per bushel, 50 to 60c. *Potatoes*—Per bag, 60c to $1. *Sheepskins*—70 to 80c.

New York Markets.—*Flour*—Dull; receipts, 7,377 barrels; sales, 5,100 barrels at $8 40 to $9 for super State and Western; $9 60 to $10 05 for common to choice extra State; $9 50 to $10 50 for common to choice extra Western; $9 60 to $13 60 for common to choice extra round hoop Ohio. *Wheat*—Unchanged; receipts, 7,600 bushels; sales, 56,000 bushels at $2 37 to $2 38 for No. 2 spring; $2 46 for No. 1 do; $2 78 for Amber Penna; $2 82½ for Amber Canadian. *Rye*—Firmer; sales 9,000 bushels Western State at $2 05 to $2 07. *Corn*—Easier; receipts, 31,900 bushels; sales, 41,000 bushels at $1 17 to $1 18½ for new and old mixed Western afloat and in store. *Barley*—Quiet. *Oats* Firmer and quiet; sales, 12,000 bushels at 83c for Western afloat. *Provisions*—Pork dull and heavy at $23 63 to $23 85 for new mess; $27 50 to $27 62 for old do. *Lard*—Quiet and steady at 19c to 19½c.

THE CANADA FARMER is printed and published on the 1st and 15th of every month, by the GLOBE PRINTING COMPANY, at their Printing House, 26 and 28 King Street East, Toronto, Ontario, where all communications for the paper must be addressed.

☞ Subscription Price $1 per annum, (POSTAGE FREE,) payable in advance. Bound volumes for 1864, 1865, 1866 and 1867, may be had for $1 30 each. Subscribers may either begin with No. 1 of the present Volume, or with the first No. of any preceding volume. No subscriptions received for less than a year, and all commence with the first number for the respective years.

CLUBS will be furnished at the following rates:—

TEN COPIES for ..... NINE DOLLARS.
TWENTY COPIES for ..... SIXTEEN DOLLARS.
FORTY COPIES for ..... THIRTY DOLLARS.
ONE HUNDRED COPIES for ..... SEVENTY DOLLARS.

To Agricultural Societies ordering more than 125 copies, THE FARMER will be sent at SIXTY CENTS.

THE CANADA FARMER presents a first-class medium for agricultural advertisements. Terms of advertising, 20 cents per line space. Twelve lines' space equals one inch. No advertisement taken for less than ten lines' space.

Communications on Agricultural subjects are invited, addressed to "*The Editor of the Canada Farmer*," and all orders for the paper are to be sent to GEORGE BROWN,

Managing Director.

THE CANADA FARMER

VOL. V. No. 11. TORONTO, CANADA, JUNE 1, 1868. POSTAGE FREE.

The Month.

JUNE is indeed a charming month in this climate. It is a delightful compound of spring and summer. The uncomfortable wintry chilliness is gone, and the scorching July heat has not yet come. Bright sunshine glorifies all nature; innumerable flowers display their loveliness; the fields are decked in their freshest green; the forests are bursting into leaf; while the air is vocal with the chirp of insects, the song of birds, and the gentle music of the zephyr and the breeze. Activity and beauty are to be seen on every hand.

The mean temperature for June, at leading points in our Dominion, are as follows:—

Stratford	61° 82
Hamilton	63° 50
Barrie	62° 27
Toronto	60° 20
Belleville	63° 17
Montreal	63° 66
Quebec	62° 20
St. John, N. B.	54° 53
Halifax	56° 00

As observed in our last article on "The Month," Quebec has now gained upon Ontario in the matter of heat, a somewhat singular fact in Canadian climatology. We believe also that our sister province is never in terror of a June frost. Spring is tardy and late, but when once it sets in, there are no unpleasant reminders of winter.

The present season retains its character as a model one. After a most propitious time for seeding, a remarkably copious rainfall came, not in deluging torrents, but in steady, abundant showers, thoroughly filling the soil with moisture, and yet not making it too wet for tillage. Along with the plentiful rain we have had fine growing weather, so that grass and grain have come on with great rapidity, and present a most promising appearance. An unusually large breadth of land has been sown, owing to the favourable character of the season, and should no unpropitious circumstances intervene, the prospect is fair for most abundant crops. There is, so far, a fine promise of fruit. The orchards are ablaze with blossom. The plum and cherry trees have outdone themselves this year, in abundance of bloom, so much so that everybody has felt that they were worth the ground they occupy for the transient show made in flowering, even though they yielded no fruit. Strawberries, currants, and gooseberries are also full of blossom. There is the same profusion of bloom in the woods, furnishing a considerable honey yield, of which "the little busy bee" is taking all possible advantage. Apiarians as well as agriculturists have hope of a remarkably good season. The indications are for early and strong swarms.

Nothing can exceed the splendour of the woods and the lovely "garniture of the fields," at the present time. There are more tints of green in nature's great show-room than the most skilful painter could compound to order, were he put upon his mettle for the credit of his art. Go where you will, "there is beauty all around," except where man has constructed some unsightly structure of which all surrounding objects appear to be ashamed. How strange it is that people do not catch the contagion of loveliness from nature. It is possible to throw an air of taste and refinement over the simplest and cheapest buildings, and surely we should aim to do this, for what right have we to disfigure a world which the Creator has made so beautiful!

It has been observed with much truth that "in no month of the year are the prose and poetry of farm life more mingled than in June." The nice poetry of pleasant views amid the fields and forests, does not relieve us of the stern prose of planting potatoes and hoeing weeds. As a natural result of the features of the season above-noted, there is a prodigious array of weeds bristling up with a sort of instinctive ubiquity. It will be a tough battle to keep them down, judging from present appearances. Many a vegetable bed, potato patch, and corn-field will succumb before them. There is no way to succeed in the strife with weeds but to take time by the forelock. Like evil habits, they are easily subdued before they have obtained strength, but when once they have secured a foothold, it is not easy to uproot them. The cultivator, horse-hoe, hand-hoe, and garden-rake, must be kept in motion early in the season, if these pests are to be overcome.

June is the month for putting in corn, turnips, and buckwheat. All these crops ought to be grown more extensively. For some reason or other many Canadian farmers have a prejudice against Indian corn, which is a most useful grain, and gives a good yield if a suitable variety is planted. It is useless to attempt the large Western corn in this country, but the eight-rowed yellow and similar kinds will ripen and produce well. It is not the least advantage of a corn crop that, requiring as it does clean culture, it leaves the land in such excellent condition for future use. For green forage there is nothing equal to a piece of corn sown broadcast. It will give a greater weight of forage than any other vegetable, and from its juicy nature it forms a most excellent article of diet for milch cows. Every dairyman should have a patch as a reserve for the times when pasture is scant. We would reiterate the advice given a month ago about turnip-growing. The farmer who fails to have a field of turnips doesn't know what is good for himself, for his stock, or for his land. Buckwheat should be grown for the flour, and also as a green manure crop, than which there is no better.

All through the summer-time, there should be the most rigid economy and care exercised in regard to all manurial substances. The compost heap ought to be growing and ripening along with the grain crops. Keep scraping up and mixing together cattle droppings, poultry dung, kitchen refuse, fence corner sods, garden weeds, swamp muck, and ordinary soil. No fertilizing material should be suffered to waste.

Barns, hay mows, and sheds, must now be put in order to receive hay and grain. Mowing and reaping tools should be provided and put in working trim, that there may be no time lost when the grass and grain are ready to cut.

Dairy operations are now in full blast. Be it remembered that cleanliness is the first law respecting these operations. Aim to make butter and cheese of the first quality, and so secure the highest market price. Sheep-washing and shearing now claim attention. They should be done in settled warm weather, and the newly shorn animals ought to be housed at night and during storms until they become used to the loss of wool. By the end of June the first crop of clover will be ready to cut for seed. All and sundry who have Alsike clover are hereby counselled to save the seed. It yields liberally, threshes easily, and the hay is but little the worse for thoroughly ripening. The valuable qualities of this clover are beginning to be appreciated, so that the seed is likely to be in demand at a remunerative price.

Orchards will repay extra trouble and attention in the way of stirring the soil, harrowing in a liberal supply of well-rotted manure, and exterminating insects. This is a busy month in the garden, and more than our whole page would be required to give even a brief calendar of seasonable operations. June is also an important month with bees. There are many improved methods in connection with swarming, securing surplus honey, Italianizing an apiary, and keeping stocks in good order, to understand which, bee-keepers should provide themselves with such a manual as Thomas's "Bee-Keeper's Guide."

The Field.

Weeds

WITH what wonderful prolificacy the soil brings forth weeds? How provoking it is to see your newly harrowed field, or your just completed garden, bristling up with an army of young weeds. The expletives of hard-working farmers and gardeners against these cumberers of the ground are uttered with an energy which leaves no doubt of their sincerity and earnestness. When you come to facts on this subject, the prolificacy of weeds is something terrible to contemplate. Dr. Lindley estimates, as a low average, the following number of seeds from each of the four plants named.

1 plant of	Groundsel	produces	2080	seeds.
1 "	Dandelion	"	2740	"
1 "	Sow Thistle	"	11040	"
1 "	Spurge	"	540	"

Here then is a good chance for the growth of 16,400 plants, or enough to cover three acres and a half at three feet apart! To hoe this land, Dr. Lindley says, will cost 6s sterling per acre; and hence a man throws away 5s 3d a time, as often as he neglects to bend his back and pull up a young weed before it gets into flower. He recommends every gardener whose vertebral column will not bend to pull weeds, to count the number of dandelions, thistles, &c., on the first square rod he can measure off. It would be well for a similar estimate to be made as to the pig-weed, mullein, fox-tail, chick-weed, burdock, purslaine, and last, but far from least, Canada thistle, which so abound in this country.

Not only the prolificacy, but the ready growth of weeds, forms a most formidable obstacle to good husbandry. They seem to spring up and flourish as if there were some special provision in the soil to favour their quick development. They always outgrow the useful forms of vegetation, unless you can favour them in some way, and give them a start in advance. No sooner is one generation of them destroyed, than another starts into life, and it often seems as if the ground literally swarmed with the seeds of these noxious things. Many of them also are very tenacious of life. A war of extermination, root and branch, is the only thing that will do for them. Leave the least sprig or fibre of them in the soil, and they quickly re-establish themselves.

Yet, after all, these discouraging facts about weeds have another side to them. The same provision for quick growth which fosters weed-life, is necessary for the useful forms of vegetation. Our hope of smiling and abundant harvests rests on the same laws of nature under which weeds fructify so fast, and multiply so fearfully. Moreover, weeds, by their presence and growth, rouse up energy on the part of the tiller of the soil, and compel that constant shaking and loosening up of the ground which is necessary to high and successful culture.

There is only one way of dealing with these pests. They must be got rid of. It is of no use to tamper with them, or to be satisfied with half-way measures. To mow them down and let them speedily grow up again, —to leave them by the fence side and in the fence corners to mature and scatter their seed,—to let them get into flower and then cut them down when they have vitality enough to perfect their seeds, leaving them to wither and die on the ground,—these are some of the slip-shod make-believe methods of destroying weeds. An energetic thistle or mullein laughs at such half-way work, and will infallibly increase and multiply in defiance of it. We must wake up to the necessity of thoroughly eradicating weeds. People ridicule the idea of legislating on this subject, but the evil is becoming so serious that something effectual must be done; and if public sentiment cannot be created, such as shall secure weed extermination, law must try its hand. In Michigan they have statutes on this subject, that even forbid throwing weeds into the highway; and if we had a law requiring utter eradication of weeds, though its enforcement would be troublesome and expensive at first, it would be in the end a most beneficial piece of legislation, under which the material interests of the country would prosper greatly.

The Germantown (Penn.) *Telegraph*, commenting on this subject, says:

"The cleanest and best farm we ever saw was that of the 'Highlands,' belonging to the late Mr. George Sheaff, in Montgomery County. In a tract of land of over three hundred acres there was scarcely a weed to be seen, so thoroughly were they destroyed as they appeared. The fence-corners, usually the hot-beds for the propagation of bastard vegetation, Mr. S. had systematically cultivated; and he informed us that he raised enough hay from these worse than neglected spots to pay all the expenses of the weed-destroying process.

"Farmers should make common cause against all noxious products; for it is folly for one farmer to begin the war, if his neighbor befriends the enemy. That which, with every good farmer, is a law unto itself should be found in black and white in the statute of every state in the Republic—an enactment requiring the destruction of all noxious weeds before the maturity of their seeds. If such a law could be enforced, it would be a blessing to the country of incalculable worth. There is scarcely a neighborhood which does not have to endure one or more careless, slovenly farmers. These easy fellows will keep the whole community in a wakeful and laborious watch, in destroying vile weeds, the seeds of which were allowed to mature on their farms, and which birds and winds carry and scatter everywhere. Such men will never learn from the precepts and examples of others to destroy these pests; and the only means of redress for the sufferers is to have a stringent weed-law passed, and then enforce it. The penalty should be a fine, and go into the school-fund. To some this may appear a matter of little consequence; but let such live by the side of a weed-growing farmer for a few years, with only a rail-fence to separate their clean fields from the burry, docky, thistly, sorrely, red-rooty, pig-weedy, briery fields of such a pretender, and they will be satisfied there are certainly consequences which rail-fences or even stone-walls do not check; and there is little doubt that then they will be ready to put proper estimate upon the matter, and to go in heart and hand for a weed-law the present session of the legislature."

Wild Oats.

A correspondent from Elma, named Edward Hammond, in our number of the 15th ult., makes enquiries about "Wild Oats," and the best method of extirpating them. We were in hopes that this pest had not reached Canada to any serious extent; but on enquiring we find that they have made their appearance in the County of Perth, and have for some years justly excited considerable apprehension.

We shall first describe the weed. There are two kinds of wild oat—(no doubt there may be others, but these are the best known)—the *avena fatua*, or common wild oat, and the *avena sterilis*, or great wild oat. Both these kinds have annual roots. They are taller plants than the cultivated oat, and of much stronger and grosser growth. They stand the winter and produce their crop of grain earlier than any grain with which they happen to be mixed; and hence their chief danger. You can never be sure of cutting them in time. They have several peculiarities, but the worst one is that the grain is covered with bearded or hooked fibres, which hang on to everything they touch, whether straw, or implement, cattle, or anything they may come in contact with, so that they seem to have an unlimited power of spreading, and almost of locomotion; indeed one of the species is so furnished with these "hooks," and so much affected by damp weather, and so hygrometric, that it is termed the "*animated oat*," and when placed on paper under a glass, will of itself move on the surface of the paper by its own power of expansion and contraction. They bear any amount of cutting before the grain finally forms in the head, and if kept mown or eaten down from time to time without going to seed, they become biennial, and will live into the second season. When cut three or four times, they often throw up short seed stalks, which bear a full head of seed when only a few inches high, or when lying down amongst other crops or grass. The seed seems to be almost imperishable, and unless it can be got to germinate will lie in the ground for many years. When once it germinates, however, it must grow or die. It will thus be seen that this species has all the properties of a most dangerous and pestiferous weed. The only place in Canada in which they are known is the County of Perth, but they have spread so rapidly, that they menace the whole country.

They came into Perth in this way: one of the settlers near Sebringville, not being pleased with the Canadian barley, sent home to his native land for some seed of the kind of barley he had been used to. He got it out, and in it was found a few plants of the present wild oat. He was not acquainted with its nature, or he would of course have destroyed it; but it made so fine an appearance that he saved the seed. The next year he ascertained the fact that it would survive the winter if grown in the fall, like fall wheat, and the settlers thought they had found a great prize! The grain passed from hand to hand as a curiosity at first, and was finally sold as a valuable acquisition. It was fed to cattle, and thus commenced to spread. The newly-cleared land of that (then) new settlement, formed the best nursery the weed could have, since nothing can be done to plough stumpy and rooty land clean, and the plant thus spread and flourished. The crops were infested with the weed; what did not fall on the ground was carried into the barns, and spread into the farm yard; the travelling threshing machines carried it from place to place, and it is now become an established agricultural plague of the district. Now every one is looking to the cure, and that is a hard thing to manage. Wherever stumps and roots exist, there this weed has it all its own way, unless every plant is pulled out of the ground; it is only in the absolutely cleared land there is any hope of its extirpation.

Many persons flatter themselves that they can get rid of the wild oat by laying the land down to grass. They do get rid of it for the time, but every grain of seed which lies at too great a depth to germinate, remains in a sound state, ready to come forth into a plant on the first favorable opportunity; this is now a proved fact in Perth.

Fallowing in a such a manner as to cause the seed to germinate, and then ploughing under, is a sure cure, so far as it goes; but you can never get to the end of the seed in the ground; they seem to *sink* into the earth, and to hybernate until a favorable season occurs.

Harrowing or scuffling the stubbles, is an excellent plan; by so doing all the oats that are on the surface and ripened before the crop grow, and are then killed by the plough. But a combination of all these methods is all that can be depended on.

The growth of the wild oat is so luxuriant that it altogether heads the wheat in the spring, and can thus be distinguished, and pulled by hand without difficulty. The surest plan, however, is to prevent their establishment. Attack them tooth and nail, from the first minute of their growth till they finally go into the barn, and your labors soon make themselves felt; but it is to be doubted if they can ever be entirely destroyed on any farm on which they have once got seriously ahead.

On the farm in England on which the writer first got any agricultural experience, there were many of these wild oats. Every means were used, and they were finally so thinned out as to be of small consequence; but just about that period, the (then) new ideas about deep tillage became known and practised, and on the farm in question one field of about of fifteen acres was ploughed deeper than it had before been by the depth of two inches; the field was sown to peas; but, to our astonishment, it seemed to come up in grain. Wild oats were not thought of, but they were the intruders. As soon as their well-known rank growth and dark glossy leaves were recognized, the danger was appreciated, and the entire crop of oats and peas (and a most luxuriant crop it was) was fed off by sheep, and cut and carried in a green state for cattle and horses. Not one grain ripened, and we thought we had got rid of them; but

the next year they came again, and kept all hands busy for weeks pulling them out from amongst the next crop, and it was several years before the plague was stayed.

The stalks and leaves are not well relished by cattle and sheep; they are bitter, and when other provender can be had, they are refused. They are not hurtful, however, and animals when confined to them, will do well on them and eat them up clean.

Any one may thus see what a dangerous pest this is, and if ever a law was required it is against "wild oats." Thistles are nothing to them. A thorough summer fallowing, with so frequent ploughing as to prevent their ever "showing green"—from five to six times during the season—will absolutely free a field from thistles; but wild oats only "hide their time." So long as the seed is in the ground, so long you may be sure that in time, and under favorable circumstances, they will again appear in a greater or less degree.

If the wild oat could be hybridized (a most hazardous undertaking, however,) and made to produce berries as heavy and nutritious as Angus, or black oats, they would become a valuable crop, on account of their earliness and hardiness; but we fear the time is far distant when this will be done. Meantime, utter destruction is the only course which can be safely pursued.

Potato Growing.

To the Editor of THE CANADA FARMER:

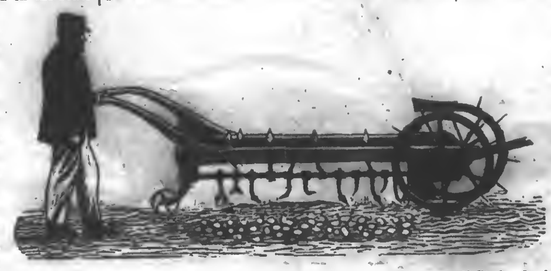
SIR,—In your issue of March the 16th, I noticed the remarks of E. R. S., of Napanee, on growing potatoes, a subject which, if properly discussed, I consider of very great importance. It appears to me that he has not done justice to it, although I agree with him in the sentiments expressed in the commencement of the article. They are very good as far as they go, but I think he has laid too much stress on the ignorance of his neighbours. I have frequently visited that part of the country, and I think that E. R. S. has very different neighbours from the class which he has represented. He should surely admit that the reason of the light crops last year was in consequence of the dry season: In the neighbourhood where I reside, I saw whole fields where the ground was well cultivated, that did not yield more than one quarter of a crop. In consequence of the extreme drought, many farmers did not plant any potatoes. The wet in spring continued so late, that they thought it useless to make any attempt after the season was so far advanced. This, I think, accounts for the light crops last year. He gives us his experience with regard to preparing the seed and planting. I agree with him in cutting the large ones, but those that are too small to cut once should be fed up, as I think the practice of planting small potatoes should not be indulged in. In the township where I live, farmers prepare their ground by manuring, and summer fallowing if necessary, and also their seed by cutting in such a manner that there are from three to five eyes on each piece. They cut a light furrow, drop the cuts about one foot apart in the drills, and put the rows about twice that distance, cover with a plough, and when they are about coming out of the ground, put on a harrow with teeth two or three inches long; harrow once in a place; the potatoes being in the furrow, will not be disturbed. This levels the ground, destroys the weeds, if any, and gives the potatoes a good start. They are then left until ready to hoe, which is done by ploughing through them with a shovel plough. If this is properly done, there is very little occasion for the hoe. In this way I have raised and seen others raise very remunerative crops. I think it would pay E. R. S. to cut his potatoes very small, if he only wants four stalks in one hill, for the smallest potatoes have from ten to fifteen eyes; and to put in the whole potatoes would certainly produce more vines than four.

A SUBSCRIBER.

Ernestown, April 29th, 1868.

Hay Tedders.

A CORRESPONDENT of the *Co. Gent.* expresses the opinion that the Hay Tedder is not sufficiently appreciated. In this I fully agree with him. Having a large crop of hay to secure the past season, and believing in the use of improved and labor-saving implements, I determined to test the value of the tedder. After getting what information I could, and examining different patterns in the market, I purchased "Garfield's," manufactured by the Ames Plow Co., which they have exhibited at the fairs this fall; on which, they informed me, they had expended $20,000 in perfecting. After cutting with the machine, we started the tedder, which turned up the grass, and left it lying up light so that the sun and air could act upon the whole. This made the labor of raking very easy. In a good day, by repeating the process two or three times, the hay would be made sufficiently dry to go into the barn. It turned hay, spread from the cock or windrow with great rapidity, and much better than by hand. One advantage of this tedder is that the hay is not raised more than eighteen inches from the ground; and should the wind blow, it is not scattered where it is not wanted. I have never used an implement with better satisfaction. It is of easy draught for one horse. It performs its work better and much quicker than by hand. In *catching* weather, as in the past season, there is less risk from damage. In curing second crop, its services are invaluable. Every one knows the difficulty of getting it sufficiently cured. Hay dealers inform me, that since the advent of mowing machines, the quality of the hay is not so good as formerly. The grass lying flat, the top is made too much, while the bottom remains green. This is remedied by the tedder, as it is mixed indiscriminately, giving all parts an equal opportunity to make.—*Co. Gentleman.*



Prize Potato Digger.

AMONG the implements exhibited at the Provincial Exhibition last fall was a very effective looking Potato Digger, which we briefly noticed at the time. The first prize was awarded for this implement. We have since seen testimonials in its favour by persons who have actually used it, and who speak in high terms of its efficiency. The accompanying illustration will give some idea of its general appearance and mode of working. It is drawn by two horses; one on each side the furrow. The large wheels in front are connected by their axle and cog-wheels with a rod running underneath for the whole length of the implement. This rod is furnished with shovels or teeth, projecting sufficiently to enter the ground, as the rod revolves, and passing below the tubers without cutting them, to throw them out to some little distance on one side. The two hinder teeth are forked, to take up the smaller tubers left by the others. The rod revolves pretty rapidly, and the dirt and the tubers are separated as they fall to the ground, the latter being thrown further aside, so as to be partially cleaned in the operation. The inventor is Mr. Alfred J. Lemon, of Lynden, Ontario, to whose advertisement in the present issue we refer the reader for further information. We believe the price of the implement is somewhere between $30 and $40. It will be to the interest of manufacturers to make them as cheaply as possible, otherwise farmers will continue to dig their potatoes with the plough.

Varieties of Wheat.

To the Editor of THE CANADA FARMER:

SIR,—Believing that it would be a general benefit if the numerous readers of your excellent paper were to contribute their experience in testing different varieties of farm produce, I will give you mine with the following varieties of wheat, viz.: White California, Italian White Mediterranean, Virginia Blue Stem, Norfolk Red, Bald Mediterranean, Boughton White, and Diehl. The first four were winter-killed, and the remaining three varieties have wintered first-rate and promise well.

Of the Diehl wheat I had an average of forty-four bushels per acre from nine acres sown last year, and for hardiness, productiveness and quality, I consider it superior to the other varieties named.

I am, Sir,
Yours, &c.,
LEWIS SPRINGER.

Hamilton, May 13th, 1868.

Cabbages, Kohl-Rabi, and Rape

WE learn from *The Farmer* (Scottish) that in 1866 "nearly six per cent. of the land, under green crop cultivation, in England; three and a half per cent. in Ireland; and seventy-five per cent. in Scotland, was occupied with cabbages, kohl rabi, and rape. In the different English counties, the extent of ground under these crops varied greatly; thus, in Cambridgeshire, they occupied twenty per cent. of the area under green crop; in Lincolnshire, ten per cent.; and in Northumberland, two per cent. They are found in all parts of Ireland, though they are most extensively grown in the midland and southern counties. In Scotland, they were cultivated most extensively in the counties of Lanark, Dumfries, and Edinburgh; however, no county contained more than 500 acres, and in no instance did they grow three per cent. of the green crop. In Orkney and Shetland, 355 acres were grown; 2.19 per cent. of the area under green crops."

It is doubtless one of the faults of Canadian farming that such crops are not more extensively grown, supplying as they do a juicy food of which stock are very fond, and helping to form a desirable rotation which leaves the soil in a very mellow state. We scarcely remember any instance of a field of cabbages being raised in this country for feeding to cattle. The same remark may be made in reference to Kohl-rabi. Has any one given this plant a trial in Canada, and if so, with what result? Rape we have occasionally seen, but its culture is a very rare thing. Those who are going into the breeding of improved cattle and sheep, will find it to their advantage to grow such crops. Dairymen also should turn their attention this way. At seasons when the pastures fail, they come in very oportunely, and in the winter time, nothing is more relished by stock than such succulent food as a change from dry and often dusty fodder. Crops of this description are easily raised, and with proper implements and good methods of culture, the labour connected with them is nothing like so great as many people erroneously suppose it to be.

THE VALUE OF TOWN SEWAGE.—In his account of the consumption of 35,000 tons of London sewage in 1867 at the Lodge Farm, Barking, Mr. Morton has the following remarks:—"I believe we have proved that every hundred tons of sewage used during the past year have actually produced, under circumstances of average favorableness, one ton of grass over and above the quantity needed to pay an ordinary rent and an ordinary farm labor bill."

Canadian Natural History.

The Skunk.

(Mephitis Americana.)

Among the Carnivora there is a well-defined family that are distinguished by their quick and active movements and by the special adaptation of their long and flexible bodies for insinuating themselves into narrow and tortuous passages in search of their prey. This is the weasel family, of which the principal specimens in this country are the mink, the skunk, the weasel, and marten. The first of these has already been described in the Canada Farmer; the second is the subject of the present notice, and the accompanying illustration, the latter copied from a specimen in the University Museum. Almost every one in Canada who lives in the country has either seen the animal, or knows something about it by means of another sense than that of vision, and if he has ever smelt the creature, we venture to say, will never forget it. Nearly every member of the weasel family is distinguished by a strong odour, but the skunk is in this respect pre-eminent. The offensive, pungent, and sickening effluvium of this animal is not, however, at all times emitted, though we doubt very much if the creature is ever sweet. The source of this peculiar odour is an oily fluid secreted by small glands near the root of the tail, and capable of being ejected by the animal at pleasure in a small stream and to a considerable distance. A few of its near relations possess, though not in an equal degree, the same peculiar means of defence; and a similar instance is furnished by a marine animal very unlike the skunk in every other respect, namely, the cuttle-fish, which when attacked or in danger, baffles its pursuers by emitting in very considerable quantity an inky fluid, serving not only to deter pursuit by its offensive nature, but to envelope the animal in darkness, and thus afford the means of concealment.

In general form and appearance the skunk possesses the usual characteristic conformation of its tribe. It is about eighteen inches long, tail included. Its head is small, the snout short, the ears small and rounded. The fur is coarse, and of little or no commercial value. The tail is long and bushy. The color is subject to considerable variation; but the general shade is black or dark brown, relieved by one or more distinctly marked stripes of white. The fore feet are strong, furnished with five stout claws, well adapted for burrowing. The legs, like those of all its family, are very short.

Its habits are nocturnal, and it feeds principally on mice and other "small deer," being specially fond of the poultry yard, where its depredations among the eggs and young chickens are much dreaded. During summer the windows of cellars are sometimes left open for the sake of coolness, and if not protected by wire gauze or some similar covering, the creature is apt to make a prying and predatory visit into the house. Woe betide the inmates if they attack it while under their roof. The house would retain the horrid stench for weeks afterwards. The safest plan is to let the animal alone, and it will quietly take its departure. Dogs, unless they are the veriest puppies or trained veterans, will seldom attack it, and if they do, are almost certain to receive such a discharge of the fluid artillery over their bodies as to render them for a long time afterwards intolerable to all about them. Some dogs, however, acquire the art of killing it instantly, by a sudden spring and grip before it has had time to emit its offensive liquid. It is said also that if the tail be held down, or the animal be suspended by that member, it is deprived of the power of ejecting the pungent secretion.

It is usually of a peaceful and quiet disposition, and only when attacked or irritated does it bring into requisition its peculiar means of defence. It is, moreover, notwithstanding its ill odour, of some use to the agriculturist, destroying a great number of noxious insects, grubs and small animals, whose depredations would otherwise seriously affect the farmer's crops. It is rather a graceful-looking animal, and, confident in its power of self-protection, will allow and almost invite a near approach; so that strangers to its habits are not unfrequently allured by its apparent docility into an attempt to capture it. The consequences baffle description. A friend received a visit from a travelling pedler in Illinois, who had just met with such an adventure on the prairie, having encountered and tried to catch, he said, "such a pretty little black and white creature, with a bushy tail." He wanted accommodation, and our friend's hospitality was sorely put to the test. The pungent secretion which the animal employs for its defence is said to possess valuable medicinal virtues as an anti-spasmodic. Its sickening and offensive odour must, however, prevent its use to any extent. Mr. Wood, in his Natural History, relates the case of a minister who was in the habit of using it, not internally, but through the medium of his olfactories, as a remedy for spasmodic asthma, to which he was subject. For this purpose he carried about with him a small quantity in a smelling-bottle. On one occasion, feeling his breathing oppressed whilst preaching, he had recourse to his usual remedy. Whether he obtained the desired relief is not stated, but the effluvium which pervaded the church as soon as he removed the stopper of his smelling-bottle speedily dispersed the congregation, and saved him the trouble of finishing his sermon. Strange as it may seem, it is nevertheless a fact, that the flesh of this animal is used as food, and is said by those who have not been deterred by the natural prejudice entertained against a beast so odoriferous, to be sweet and palatable, resembling somewhat the flavor of roast pig. On the whole, however, while we would give the creature all credit for any service he may render, we think he can be well dispensed with either from the larder or the pharmacopœia.

How to Skin a Bird.

To the Editor of The Canada Farmer:

Sir,—Seeing in your journal occasional enquiries concerning the best methods of removing and preserving the skins of various animals, I venture, having some experience in the art, to send the following directions for skinning any bird of moderate size, such as a wild pigeon.

When you have shot such a bird, which you intend for stuffing, first examine the wound, not by pulling off the feathers, but by gently putting aside the feathers right and left with your fingers, and by blowing into them. Then stuff the wound, throat and nostrils, with tow, cotton, or rags, and wind a small quantity round the bill. Have a moist sponge with you to remove any spots of blood that may be on the feathers. Take the bird by the legs to the place where you intend skinning. Lay it on a table, on its back, with the feet from you, and the head towards your left elbow. Separate the feathers on the breast bone to the right and left; pull off the down; then cut through the outer skin and no further, with a sharp knife. Cut from the beginning of the breast-bone to the vent. Have a little powdered chalk by you, so that when you have skinned a part of it you can dust the skin with chalk, and it will not adhere to the flesh when you leave off. By using a blunt stick or the handle of your knife you can skin to the back. The thighs should now be pressed inwards, and the skin turned back so far as to enable you to separate the legs from the body at the knee joint. The skin is then pulled downwards as low as the rump, which is cut close by the insertion of the tail, but in such a manner as not to injure the feathers. The skin is now drawn upwards the length of the wings, the bones of which must also be cut at the shoulder joints. It is then pulled up until all the back part of the skull is laid bare, when the vertebræ of the neck should be separated from the head, and the rest of the body from the skin. You next must grind an iron teaspoon sharp, and remove the brains from the skull bone; and by breaking a few tender bones inside of the eyes, you can take them out by pressing them inward with your fingers. The whole of the flesh is now to be removed from the under mandible, also from the head, wings, legs, rump, and the cavity of the skull filled with cotton or tow. The whole inside of the skin, head, &c., must now be well rubbed with arsenical soap, spirits of turpentine, or the solution of corrosive sublimate, then the skin inverted and hung up to dry. Pack in white paper, with a little powdered camphor, to prevent the insects from destroying the skin.

A. B. B.

Curious Freaks of Birds.—At Cornwall station, and within a few feet of the platform at which the trains arrive, a robin has built a nest on a tree on which the leaves are only budding. It is now sitting on its eggs, undisturbed by the traffic, the whistle of the engine, or the noise of the cars. But this conduct is not singular in the case of the Cornwall birds. A few years ago one built its nest on one of the ties of the railway bridge over which trains pass constantly, and there it reared its family respectably, until they were of an age to get on the fly.

Mammoth Pigeon Roost.—The *Commercial* says: A gentleman who has just returned from Pennsylvania, informs us that there is a pigeon roost near Port Alleghany, in that State, some ninety miles from Buffalo, covering an area of fifteen miles in length, by five to six miles in width. Over six hundred Indians and a thousand white men, we are told, were on the ground recently, and cut down much valuable timber to get the "squabs"—doing much damage. Over two hundred barrels of squabs were sent to New York in one day.

Stock Department.

The Circulation of the Blood.

The general character and properties of the blood having been described in a former article, the manner in which it circulates throughout the body comes next under consideration. To understand this it will be well to take a general view of the course of the vital fluid throughout the system, and afterwards consider the subject a little more in detail. In the higher type of animals there is one general plan of the circulation, and a description of that in the human subject will apply to the other warm-blooded animals. The grand motive power in the process is a sort of muscular force-pump called the heart, a hollow cavity with thick fleshy walls, divided into four compartments. From this hollow muscle the blood is forced into tubes, which may be compared to the hose attached to the force-pump; and by these tubes, which divide into innumerable small branches, it traverses the whole body, and is returned by similar tubes, after completing its circuit, to the heart. In this course it has served many most important vital functions, and has consequently undergone considerable change; so much so, indeed, as to be unfit without some purifying process to traverse the body again. Before, then, it is sent once more through the general system, it is propelled into the lungs, where it is exposed to the influence of the air, which in a wonderful manner restores it again to a fit state for performing its functions. It is then returned to the heart, after this lesser circulation, as it may be called, and is ready to perform again the general circuit of the body.

How this double circulation is effected will be readily seen by reference to the accompanying diagram (fig. 1). The heart is here represented, divided into four compartments or chambers, two on each side; and it will be observed that while the two on the same side have a free communication with each other, those of one side are completely separated from those of the other. The upper chambers are the smaller, and receive the blood from the tubes already spoken of, or blood vessels. These smaller cavities are called *auricles*, or little ears, because they are furnished with an over-lapping appendage which gives them a resemblance to an animal's ear. The lower, larger, and more muscular chambers are called *ventricles*. These receive the blood from the auricles, and force it out into the main trunks of the blood vessels. These vessels, or tubes, that convey the blood from the heart, are called *arteries*, from Greek words signifying to contain air; because being always found empty after death, their function was supposed to be that of containing air. Their true office and character were discovered in comparatively recent times, by an eminent physician, William Harvey. Those vessels which convey the blood back into the heart are somewhat differently constructed, and are called *veins*. Intermediate between these is a set of extremely minute tubes which have received the name of *capillaries*. Now, to make the matter plain, let us, even at the risk of a tedious repetition, follow the blood once more in its double circulation through the system and through the lungs. The diagram, in which the course of the fluid is indicated by the arrows, will assist the explanation. Let us commence on the right side. Here the returning blood, having been collected into one large venous trunk, is thence poured into the right auricle, and partly into the larger cavity on the same side, the right ventricle. The smaller cavity is, however, soonest filled, and when it is filled, under the influence of some wonderful nervous energy, it suddenly contracts, and forces its contents into the ventricle. A little may flow back into the veins; not much, however, can return in this direction; for the base of the large vein is surrounded with muscular fibres that, contracting simultaneously with the auricle, very much diminish the diameter of the tube, and a little way back the vein is furnished with valves which effectually stop its regurgitation. Hence, nearly all the contents of the auricle are discharged into the ventricle. This is in turn filled by the additional influx of fluid, and by a forcible contraction of its muscular fibres expels the blood into the large arterial trunk called the pulmonary artery. The return of the blood into the auricle is prevented by a beautiful fringed valve, which is situated in the opening between the two chambers. The delicate membranous flaps of this valve hang flaccid in the lower chamber while the blood is flowing into it, but as

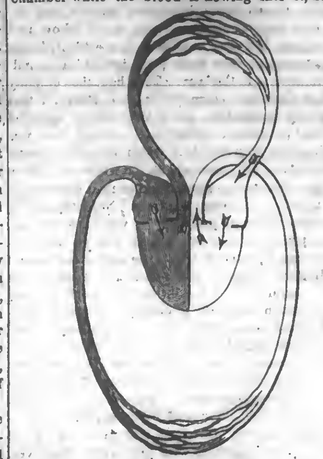


Fig. 1.

soon as the ventricle contracts, they are drawn together across the opening, and effectually close it. The base of the arteries is also furnished with a valve which allows the blood to flow onward out of the heart, but prevents its return into that organ. From the right ventricle the blood is forced into the pulmonary artery, and by means of its ramifications is distributed in the minute capillaries of the lungs, where only the thinnest possible membrane interposes between the vital fluid and the air inhaled by the air passages. The air permeates these membranous walls with perfect ease. The oxygen of the air is absorbed by the blood, while the noxious portions of that fluid, derived from the various tissues in the course it has just completed through the body, are given off into the air, in the form principally of carbonic acid. These changes alter the colour and other qualities of the blood, and render it fit to circulate through the body again. The blood in the veins

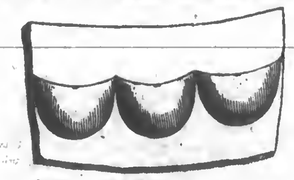

Fig. 2.

and right side of the heart is dark-coloured and impure. After its exposure to the air in the lungs, it is purified, acquires fresh oxygen, and again assumes a bright scarlet hue. It is now collected together by the pulmonary veins, and at length reaches the heart again, and is poured by a single trunk into the left auricle, thence into the left ventricle, and by its powerful contraction is ejected into the main artery of the body, to pursue once more its appointed course through every part into the smallest and most remote capillaries, thence to be collected and again brought back by the branches of the veins into the main trunk on right side of the heart.

The valvular apparatus which prevents the return of the blood from the main arteries into the ventricles, will perhaps be understood by the aid of the accompanying cut (fig. 2). This shows a small portion of the base of the artery, cut open and flattened out, disclosing three small pouches, of a half-moon shape, attached to the walls of the tube by their greatest convexity, and free at one margin. These little sacs lie close against the sides of the artery as the blood is forced outward from the heart. The walls of the arteries are highly elastic, and are distended somewhat by the force of the onward current; but as soon as the action of the ventricle ceases they contract again by virtue of their elasticity, and this will send the blood behind the free margins of the little sacs, and fill them out. Thus distended, they are pressed closely against each other, and completely close the tube. By the combination of these valves the blood is compelled to flow in one direction only. The mechanism is extremely beautiful, and can be readily seen by any one who has sufficient curiosity to examine a sheep's or bullock's heart. The four cavities and the valves between the auricles and ventricles can also in the same manner be submitted to ocular demonstration.

These preliminary explanations have already occupied sufficient space, and extended the article to as great a length as is perhaps desirable. We must therefore defer to another issue some account of the peculiarities of the arteries, capillaries, and veins, the cause of the pulse, and its frequency in different animals, with other interesting particulars.

Discussion on Washing Sheep.

There has recently been considerable discussion amongst our neighbours in the United States on the question of washing sheep, showing, though many still strongly advocate the importance of thorough and careful washing, a growing feeling, nevertheless, in favour of discontinuing the practice altogether. The following report from the *Rural American* of a discussion on the subject at the last Sheep Fair, held at Canandagua, New York, gives the pith of the arguments on each side:—

Hon. Geo. Geddes, of Onondaga, remarked that he had made it a practice to wash the wool on the sheep's back, that he still practised it, and believed there were advantages to be secured by so doing. He also cited the case of a gentleman in Ohio, who had made some experiments going to show that it is better to wash sheep, and sell the wool without deduction or tare, than to shear without washing, and sell at one-fourth deduction. It was the opinion of Mr. G. that we shear too early. He thought that the oil should be allowed to start before shearing. In his case he always put his sheep in a dry, clean pasture after washing, and allowed them to remain there until the wool got dry, and the oil started. He also thought, if sheep were properly handled, there was no danger of losing them by taking cold by washing.

Mr. Holmes, of Washington Co., stated that he formerly held opinions similar to those of Mr. Geddes; but that for the last five years he had been trying experiments, and found that his sheep sheared early did better in May, and the first half of June, than they did when they were allowed to run till that time with their fleece on. In his opinion, if the fleece is taken off the sheep in May, the wool grows right on, and thus by shearing early the annual crop of wool is increased; consequently we cannot shear early, if we wash the wool on the sheep's backs, thereby losing the increased growth of wool. He also stated that there was a growing feeling in favour of purchasing unwashed wool among the manufacturers; the fibre, in their opinion, being stronger than when the wool is washed, there being less "fly waste," although in some cases there is more shrinking in cleansing.

Mr. R——, of New York, remarked that he had long been an advocate of anti-washing. He believed that it was not only a loss of labour, but that there was a loss in the growth of the wool, and that at the same time the health of the sheep was injured thereby. He thought that wool could be bought and sold just as well without washing, and that a dealer could judge of its value as well unwashed as washed. In his opinion, if the wool was unwashed, it would be

more likely to be bought and sold according to its merits—that the time and labor spent in washing the sheep was wasted, at the same time being an injury to them, and of no advantage to any one.

Mr. Hodgekins, of Prattsburg, N. Y., thought that the variation in unwashed wool would be so great, that it would be almost impossible for buyers to discriminate justly, and that there would be no criterion by which we could arrive at a stated price for it. In shipping unwashed wool to market, he found that there was at least thirty-three and one-third per cent. in the expense of getting it there, and that rats will eat the bags in which unwashed wool is stored. He also stated that manufacturers would buy foreign wools, rather than purchase unwashed wools.

Mr. Sweet, of Vermont, was in favour of washing sheep, if those who wash would only do it, when they pretend to do so. He was not in favour of half-way work in this matter, and if the people did not pay more attention to it than they had done, then he would advocate abandoning the practice altogether. He also thought that sheep might be sheared in April, and stand, the cold just as well as the lamb by the side of the ewe.

Mr. Noyes, of Geneva, N. Y., thought, that as the wool trade is at present conducted, we could not sell our wool without washing, and that if sheep were washed well it was an injury to them. He thought that the best and most correct way was to take the wool off unwashed, for buyers will insist on deducting shrinkage; and if we wash well, we cannot compete with these who only half wash their wool.

GOOD WEIGHTS AND FLEECE.—Mr. John Snell, of Edmonton, has sent us an account of the weights of some of his young Cotswold and Leicester stock, which, especially taking into account the unusual scarcity of feed in that section of the country, are extremely creditable to his management. He says:—"Last week I weighed six yearling rams, Cotswold and Leicester, which averaged 276 lbs., the lightest being 251 lbs., the heaviest 285 lbs., making an aggregate of 1,656 lbs. Six two-year-old rams weighed an average of 341 lbs.; the lightest 314 lbs.; the heaviest 368 lbs.; aggregate, 2,040 lbs. I sheared from a Leicester yearling ram 20 lbs. wool; from a two-year-old Cotswold ram 21 lbs.; and from a yearling Cotswold ram 22 lbs. I flatter myself that these weights are hard to beat."

The Dairy.

American Dairying.

THIS mammoth interest, which has grown to such prodigious size in an incredibly short space of time, narrates its own history in the Report of the American Dairymen's Association—a publication which ought to be in the hands of all who have anything to do with dairy business. The Report for 1867 is now before us. It is a well-filled octavo of 119 pages, and contains a vast amount of useful information upon the subject to which it relates. Besides the proceedings of the Association, which are pregnant with suggestions, facts, and the fruits of personal experience, there are papers of a permanent character, elaborately prepared, that are exceedingly valuable. One of these discusses cattle breeding in its relations to dairy farming; another, which we need scarcely say is from the pen of X. A. Willard, gives the statistics of the dairy business for 1867; a third treats of the buying and shipping departments of the business, while a fourth reviews the whole subject of associated dairying. Factory reports are also a noteworthy feature in the volume before us, and furnishing, as they do, a detail of operations and results, must be of great utility to factorymen and others.

The chief characteristics of the dairy interest during the past year seem to have been greatly enhanced production of cheese, and shortcoming as to quality, together with extraordinary fluctuation and depression in the market. While the article was never before manufactured so largely, it seems evident that the average quality of American factory cheese last year was not equal to previous years. The same thing is true of English cheese-makers. Production has been large, but along with it there has been a falling off in quality. These circumstances had of course their natural effect on the market, rendering it very changeful, dull, and low. At the beginning of the year the impression was pretty general among dealers that there would be over-production, and that the market would be flooded. Under the influence of this idea, manufacturers were in hot haste to sell as early in the season as possible, and a large amount of immature cheese, unfit for handling and unripe for shipment, was exported, much of which deteriorated and even spoiled on the hands of the consignees. Goods being thus forced forward and exposed to injury, only one result could follow, and hence great loss was entailed. It is estimated that the dairymen of New York alone lost at least a million of dollars in this way. They had the company of their Canadian compeers in this misery, if that were any satisfaction, since like causes operated here and produced a similar result, though there was nothing like the panic here which prevailed among United States dairymen, and on the whole we believe our factories averaged better prices than did those of our neighbours across the lines. Notwithstanding this depreciation of prices in the wholesale market, retail prices held their own, so that the manufacturers were mulcted in loss to the aggrandizement of middlemen, shippers and retailers. Against this there is no safeguard but in having a weekly return of production, and table of markets, accurately compiled, which being in the hands of producers, will enable them to judge whether to sell or to hold out for better rates. It was demonstrated last year that if American backbone had only been stiff enough to hold the cheese, remunerative prices would have been had. After this bitter and costly experience, it is not surprising that American dairymen took up, at the last annual meeting, with more spirit than ever, the project of establishing such a circular, and that the Canadian association voted to co-operate with them in the enterprise. A very small percentage on the production would pay the expense of such a circular, and the good it would do would be in the proportion of its cost a thousand if not ten thousand to one. But for a stupid "penny-wise and pound foolish" policy, such a circular would have been in existence long ago.

It is a noteworthy fact that, during all periods of uncertainty and depression in the cheese market, the A No. 1 article invariably commands a high figure. This fact speaks volumes as to the wisdom of aiming high in regard to the quality manufactured. Excellence of flavor in cheese is not matter of accident. Care and skill always result in securing high quality. And while the inferior article is of doubtful sale or certain to bring only an unremunerative price, the choice article is sure to be in demand and to be sold at a good profit. How strange it is that this fact, which has stood out prominently in the history of cheese factories from the very beginning of the movement, should have had so little practical effect upon manufacturers. To save a little on first cost, or to avoid trouble, inferiority is not risked merely, but deliberately chosen; for surely nobody is fool enough to expect extra quality without extra painstaking. Patrons are often very censurable in connection with this matter, because of their unwillingness to allow a fair price to manufacturers. Factories managed on the principle of association are often hurt by the niggardliness of members, who stand out for cheap manufacture, and thus render it impossible to procure skilled help. It is very short-sighted policy to save one or two hundred dollars in this way on a season's work, and for the sake of doing this, lose thousands on a season's product. It is becoming every year more apparent that those who are not prepared to take such measures as are needful to secure prime quality in their cheese, might as well make up their minds to quit the business. Many New York factories were carried on last season at a loss, and very few did anything like a good year's business; in fact, none but those at which a first-rate article was made were able to show a decent margin of profit. The practical lesson from all this is obvious enough. Our dairymen must produce a choice brand of cheese, or get very small returns, perhaps none at all, for their labour and capital.

Our American friends acknowledge in their report that the prospects of the dairy business are not so bright as they appeared at one time to be. The opinion has been prevalent that there is no branch of farming so profitable as dairying. It has been regarded by many as a direct and royal road to wealth. But a more sober view of the matter has been inculcated in the school of experience. It is now felt that there has been an inconsiderate rush into this business by parties not favourably situated for carrying it on, and that many have unwisely and rashly changed their system of farm operations in order to go into cheese-making. There seems also ground to fear over-production, a contingency hardly thought of at the outset. But so prodigious has been the growth of this business, that although the demand is very great for the article produced, there is a possibility and a danger of outdoing the demand. The indications are not such as to occasion fright, but they certainly counsel moderation and caution. Farmers who are in a well-to-do condition on a system of mixed husbandry had better be contented, lest they should have to pen their autobiography in similar terms to that of the unfortunate victim of medicine, who was well, wanted to be better, took physic, and died. Mankind will probably eat cheese while the world stands, but the earth is not made of green cheese, any more than the moon. We must have beef and potatoes, bacon and greens, ducks and green peas, as well as bread and cheese, and industrious, thrifty people, stand about an equal chance of making their fortune out of any of these commodities. It must be borne in mind, however, that good management and hard work are the conditions of success, whatever may be the line of activity chosen. "In all labour there is profit," but profit without labour is the dream of the speculator and the rogue, not the role of the honest and the diligent.

Cheese-Making—A Plea for Reduction in Price.

To the Editor of THE CANADA FARMER:

SIR,—Again I take my pen in hand to address you on the subject of cheese-making. As I intimated before, many farmers in this county will not sell any more milk, because it does not pay. With your permission, I will lay before your readers a few of the arguments adduced to show why milk-selling does not pay. In the first place, it is argued (and with reason) that two cents per pound is too much to pay to the manufacturer for making up their milk, and that the manufacturer has the largest share of the profit. Allow me to illustrate it. A man sells milk from a certain number of cows all summer, and in the fall the cheese sells probably for eight cents per pound. He has to pay two cents out of that sum to the maker, thus giving the maker one quarter of their milk. Add to that the drawing, which costs from a dollar to a dollar and a half per cow, and the waste consequent on drawing, and you will see that it costs the farmer about three cents for every gallon of milk that he sends to the factory, thus leaving the seller about five cents per gallon for his milk, a sum which all will allow is too low. Another argument brought forward is, that it costs more to keep the cows than their milk realizes. We will suppose a case:—A man in the spring buys, say ten cows, for which he pays thirty dollars apiece; he keeps these cows all summer, and in the fall he gets (as I have shown before) about five cents per gallon for the milk. Each cow, on an average, will give two gallons per day, which would be ten cents per diem. For the ten cows, this would be one dollar a day, or twenty-six dollars per month, which for the six months would be $156. If he sells them in the fall, he will probably get twenty dollars apiece, which would bring him $200; add to that the $156 for the milk, and we have the sum total of $356; the cows cost him three hundred dollars, leaving him fifty-six dollars for their pastures, his trouble in milking, paying for the care, etc. The ten cows would take from fifteen to twenty acres to keep them all summer, thus giving him $56 as the sole product of twenty acres of land. Now you will naturally enquire, is there no remedy for this? I answer, there is. Let the manufacturer make it up for one cent and a quarter per pound, or even one and a half cents, and at that rate he will still make a handsome income. I do not mean to say that he can make money at that rate unless he has the milk of at least 300 cows. He should at the least have one cent per pound clear, after paying all his expenses; and I think if they were to manufacture at that rate they would satisfy their patrons and make a handsome income for themselves. Allow me to carry the argument further. Supposing the farmer keeps the ten cows over winter, he will have to feed them, at the least, two tons of hay apiece. Now, allowing twenty dollars for the hay (the price last winter), you will see that the summer's milk does not pay for their winter food. I have heard numbers say that if they were to give away their cows in the fall and sell their hay, they would have been better off in the spring than they were. Now, some will ask what are farmers to do? Give up selling milk and go back to farming? I answer, farm and sell milk. Let a man keep as many cows as will eat up his rough feed, and let him manage so as to raise enough grain to produce straw enough to feed them in the winter, for it is a well known fact that good barley and oat straw is as good feed as a great deal of the hay used for the purpose. Then let him feed say half a ton of hay apiece, with straw and some roots, and I maintain that his cows will come out in the spring in better order than if they had been fed on poor hay all winter, and then milk-selling will pay him about as well as farming, with far less work. I hope we may see a few, at least, of the changes which I have mentioned brought about before long.

Norwich, May 13th, 1868. CURTENIUS.

NOTE BY ED. C. F.—Having allowed the advocates of the higher rate of remuneration to the manufacturer the opportunity of expressing their views in these columns, we cheerfully accord the same privilege to our correspondent and others who think with him. It is a matter in which there is naturally some difference of opinion. In order to allow the manufacturer to make at a lower price, it is necessary he should have the milk of a large number of cows, a condition which will be rendered impossible by erecting factories too near together. A judicious system of feeding, both in summer and winter, especially a more liberal use of green crops raised for dairy purposes, instead of trusting altogether to pasture, will both increase the quantity of milk and improve the condition of the land.

Early Cut Hay for Milch Cows in Winter.

AT a meeting of the Craftsbury (Vt.) Farmers' Club, Feb. 11th, Mrs. A. Scott presented a churning of butter—*eleven pounds, from the cream of one cow in six days*, nice and yellow as that made in June. Mr. A. Scott read a paper on the time of cutting grass, as follows:

The best mode I have found yet to cut hay, is to commence about the 10th of June and finish about the 25th of June if I can; sometimes the weather prevents, so I cannot finish until the first days of July. The quality of hay cut the last days in June is not worth but about one-half as much as hay cut previous to the 25th of June. When the herdsgrass puts out its heads in the last days of June, three or four inches of the buts have become hard and woody, and the nutriment of the grass is rapidly leaving the stalk. Hay cut the last days of June and the first days of July, I do not feed my cattle until I am obliged to.

The grass cut from the 10th to the 25th, produced the butter presented you this evening by Mrs. Scott, from an ordinary cow, and quite under-sized. This cow consumes 20 pounds of hay per day, and at $20 per ton costs twenty cents per day, and yields in return one and one-half pounds of butter per day, as that will be about the average for the winter. Then deduct the one-half pound to pay for milking, churning, &c., and you have one pound of butter worth fifty cents, and safe any time at forty cents, for twenty cents' worth of hay. (Vermont prices, American currency.)

Now will you consider the above figures, and make up your minds to lay aside old customs and adopt a better one, that will be sure to give you two to one, instead of feeding twenty cents' worth of hay per day, and getting nothing in return but your stock in the spring, without any gain?—*Rural American.*

Poultry Yard.

Pigeons.

READ BEFORE THE ONTARIO POULTRY ASSOCIATION BY LT.-COL. HASSARD.

For the last two or three thousand years certain pigeons have been kept by man as domestic creatures. Time will not permit me to give illustrations of this fact, though the task would otherwise be easy; but in mentioning it I wish to save the pigeon fanciers from the contempt, if I may use the expression, which is often manifested towards them. Many of us are pigeon fanciers, and we have outlived the time when a pigeon fancier was associated with costermongers, pugilists, rat-catchers and dog-stealers; and if you scoff at the fancy, how do you treat the fanciers of tulips, piccotees, dahlias, &c.? for roots of which twenty guineas are often given.

There are many places in which pigeons may be kept by artisans and others, when they have no means, in place or purse, of keeping fowls. After a hard day's toil in a rolling mill, or other similar occupation, would you not rather see a man go into his loft than into a bar? One may bring him profit, the other will not, although you may perhaps suggest against this position, that Bob in "Dombey and Son" was made to exclaim that "it was all them birds, and no good ever came of them;" and his expression "What I flowed?" in reply to an announcement that his friend had gone, could only be appreciated and understood by a fancier of pigeons. Pigeons are also of use to the farmer, both as furnishing variety in diet, and in destroying a vast number of noxious insects.

It is not my intention to go into a description of the different varieties or their derivation; this is amply explained by my esteemed friend, Mr. Tegetmeier, in his last new work; but I propose making a few practical observations on the best way of keeping pigeons in Canada. I do not think the farmer would desire to have a large dovecote on his farm, as in bye-gone days; but in France Pigeons are encouraged still as keeping down weeds, the seeds of which they greedily devour; and as they do not scratch, anything properly sown is safe from their attacks.

I find that in both Ontario and Quebec the climate seems to suit the birds. In the severest winters many may be seen about the stores at Quebec; and provided they get shelter at night under a roof, the cold does not seem to annoy them. This applies to the common sorts.

I can also state, from practical experience, that I have not found the high fancy birds suffer from cold if kept as they must be in a loft or shed, over a stable, or any building where they can perch, secure from draughts of wind and wet. My carriers are the very best English strains. I often had sick birds in England from their being so highly bred. I may say that I never had a sick bird in Canada; and the eye disease, which so often attacks carriers, has but very slightly appeared, and that only once, lasting a couple of days, in a very heavy-eyed specimen.

Pigeons require to be kept very clean; to have in summer a large shallow pan (out of the loft) to bathe in; a supply of salt or a mixture of loam earth, mortar and salt, with seeds of cummin, in order to make it perhaps more attractive, although the salt is what they like—a taste inherited from the old stock, the Rock Dove—and a hopper of food always at hand. In this particular they are more easily kept than fowls. They do not nauseate over their food, and will always go and help themselves when hungry. To keep these birds successfully, the lofts must not be over-stocked. This is of immense importance, and each pair should be provided with its own house, of two bed-rooms and a sitting-room, with the means of keeping them in at pleasure. Pigeons, when once habituated to a box, will always keep to it; hence you always know where to find them. I do not mean to say that they will not appropriate an empty pen, but this must be kept closed until wanted. After trying many plans, I have found the best to be a box three feet long, or frontage; two feet deep by two feet six inches high. These dimensions are for the larger sort of pigeons, such as penters, but all pigeons require, if we would produce successful results, more room than is usually alloted to them.

The three feet frontage has ten inches to one foot taken off for nesting places, leaving a space about two feet square for a day room. The nesting portion should be divided between top and bottom by a shelf. The partition across should not extend to the back, but leave space for the birds to get in behind. Each pair has thus two nesting places. The large apartment must be provided with a wire door, capable of being opened at pleasure, and the nesting places with a solid door. The box, complete, has the appearance of the old-fashioned rabbit hutch familiar to most of us. This construction has the advantage, that when a pair have young about fourteen days old, they can be removed to the lower compartment, leaving the upper free for another nest; so that the young can not get up and spoil their eggs. A pair of birds can be easily shut up, and having plenty of room, will do well there for some time.

Nest pans, made of earthenware, about eight to ten inches diameter across the top, and three inches high, sloped inside like a bowl, should be provided; two to each pair. They are the best appliances for nests, being easily kept clean. A little sawdust should be put in each, and with what straw the birds pick up, a good nest is made. These pans also have the advantage that, to inspect eggs or young, you merely take hold of the pan and remove it from the box without handling the birds. This construction also enables you to compel the pigeons to remain in the nest-place when you wish it. For example, supposing a stray egg is laid on the floor, you watch the hen that sits over it, catch her and her mate, and put them into the box. She will lay her second egg on the third day after the first, in the box, and will sit on it, and by returning the first egg the same evening, both are saved.

Pigeons sit seventeen days after the second egg is laid. The first egg is laid about 4½ to 6 o'clock, say on the first of the month; the second egg at 1:30 to 2:30 on the third of the month. On the twentieth both youngsters should be hatched or chipping the shell. Time will not allow me to enter into an explanation of the assistance that may be safely rendered when a youngster remains stationary in the egg. Messrs. Tegetmeier's, Eaton's and other works will assist you in this, but as a rule let the birds alone.

The cock and hen having sat by turns, will also feed by turns. You supply the food, they will do the nursing, and save you much anxiety and trouble. In a paper like the present, it is impossible to give the result of my experience in pigeon-keeping over a period of forty years. Each gentleman must select his own fancy; but if fond of a good pie, he will find Runts, weighing two pounds and over each, fill a pie quicker than any other sort. It is scarcely necessary to say much in regard to the food of pigeons. Almost any kind of grain is suitable for them, and great advantage will be derived from variety in their diet.

RECENT IMPORTATIONS.—Several enterprising members of the Poultry Association have recently imported very valuable birds from England. Mr. Howard, the president of the society, has added to his stock some splendid specimens of various breeds; among the rest, a variety known as Andalusians, which he finds excellent layers, and apparently hardy. These birds were expected prior to the last Exhibition, but did not arrive in time. Mr. Howard has also some magnificent game birds among his latest arrivals from England.

Correspondence.

The Agricultural Bill.

To the Editor of THE CANADA FARMER:

SIR,—We all acknowledge the difficulties of framing a measure that shall not be open to some doubt or question; with even the best intentions, and the use of the plainest language, it is impossible to legislate for all cases. Your correspondent, "A Secretary," in your last, and you, in your explanatory note, came very near touching upon a point unprovided for in the New Agricultural Act, but which as it affects one of the most flourishing Township Societies in Ontario, I have been requested by several brother members to propound to you for solution or discussion.

You and the majority of your readers are aware that the Blenheim Agricultural Society has existed for many years, and won for itself a reputation second to none around. The show has invariably been held at the capital of the Township, Drumbo, which, as reason would direct, is the proper place, being situated exactly in the centre. The fixing of the show here, however, be it observed, is by the rules always determined at the annual meeting by the majority of the votes of the members. Two years ago, a number of members, living in the remote north and north-west corner of the Township, feeling aggrieved that the show was not held at Plattsville, resolved to establish a society and a show of their own. Whatever may be said of the *propriety* of this step, no one can deny that these gentlemen were at perfect *liberty* to form a society to please themselves. But here comes the query. Had these parties any legal authority to call their society by the name of an adjoining township—to withdraw the principal number of the members from the Blenheim Society, and, under an assumed name, to hold their show *in* Blenheim, and (most important of all) to draw the Government allowance as an independent company or society? I cannot believe that it was the intention of the framers of the new Bill that the public money should be frittered away in such a manner, or to encourage the formation of petty societies out of every dissatisfied minority. Better far that our Township societies should be abolished altogether, or amalgamated into the County Show, as has been done in some instances. The operation of such procedure as I have briefly detailed above, must be such as to make *two poor shows out of one good one*, and so contagious is the example of insubordination and discontent, that actually the formation of *another* or *third* show in the Township was contemplated this year. A meeting was held in the South, and committee, chairman, &c., appointed. I am glad to say, however, that the Southerners have had the sense to see that they were venturing on dangerous ground, and attempting something that might lead them into a very foolish position, and therefore *that* society is meanwhile in abeyance. What we want to know is, whether the Northerners are not proceeding upon equally illegal grounds, to say nothing of the sad blow they are inflicting upon the best interests of agriculture in the east of Oxford.

BLENHEIMENSIS.

Blenheim, May 21st.

NOTE BY ED. C. F.—We do not feel at liberty to pronounce a definite opinion on the case submitted in the foregoing communication, but would suggest that the circumstances seem to call for a full explanation of the matter, and an appeal to the Department of Agriculture itself. Without knowing more than we do, we are not justified in condemning the action of the seceding parties, but must confess that they appear to be violating the spirit at least of the Agricultural Bill. Parties living in the north of the Township of Blenheim, would certainly be at liberty to subscribe to the society of an adjoining township in preference to their own, if it suited their convenience. But if a large proportion of the members, especially those who originated the society, are inhabitants of Blenheim, it is a mere evasion to assume the name of another Township, and if the society were *bona fide* composed of inhabitants of the adjoining Township, it appears to us that they are transgressing at once the rules of courtesy and the spirit, if not the provisions, of the Act by holding their show in Blenheim.

Besides the above communication, we have received two others containing queries in regard to the new Bill. The first, from R. G. F., Oldboro, is to the following effect in reference to

"AUDITORS.—"Will you have the kindness to inform me if it is the intention of the law that auditors are to be appointed to audit the Treasurer's books for the annual meeting of next year or not? If so, how will the auditors be appointed; through a special meeting of the members, or has the Board of Directors the power to appoint them?"

Sections 37 and 43 of the new bill provide for the appointment of auditors for the year 1869 and after. For the current year, 1868, the accounts of which should, of course, be made up and presented at the next annual meeting, auditors should have been appointed at the general meeting in the beginning of the present year. If they had not been so appointed, we presume it is in the power of any general meeting to make an appointment, and for this purpose the time of the fall show would be a convenient opportunity. It is not customary for a Board of Directors to appoint auditors.

The other communication is an enquiry respecting THE RESPONSIBILITY OF TREASURERS. A correspondent from Bothwell asks, "Can yon inform me if the *surety* of a Treasurer of an Agricultural Society is held responsible for a longer term than one year, or is he responsible until he notifies to the contrary?"

The Bill makes no provision for Treasurers' sureties or bonds. The office is usually held gratuitously, and a bond does not seem called for under the circumstances. Were the Treasurer a paid officer, it would be very proper to exact the usual legal security.

Farming in Quebec.

To the Editor of THE CANADA FARMER:

SIR,—Your visit, editorial, and illustrations have awakened very considerable interest among your subscribers in this Province. And though Compton, Hillhurst Farm, and M. H. Cochrane, Esq., have deservedly gained your first attention, we can assure you there are many other places, persons and operations which will richly repay editorial inspection.

Farming here differs from farming in Ontario about as much as the provinces differ. Not to speak of the French and their generally inferior modes of culture, we have in the Eastern Townships a population as mixed as in Ontario, with, however, a larger proportion of the American element.

Let me indicate a few particulars in which, I think, Ontario might profit by their example:

1st. They are not such slaves of the soil. They work, but take time to read the papers and circulating libraries. You meet a sharp intelligence everywhere.

2nd. They do not grow so much grain, nor make money so fast as in Ontario; but they take better care of their *stock*, and see that their farms are not exhausted. They laugh at the idea of cattle living on straw stacks in open yards, and cold sheds. Even their young steers must have plenty of hay and a warm stable. The drover or the butcher will be along, and stock must be saleable. I find the best farmers are very particular to have *no seed in their hay*. They cut the grass before the seed forms. Any one who will examine a carrot or a stalk of wheat *after* the seed *is formed* may learn how exhausting is the process; and thereafter have *dried grass* instead of exhausted hay, to give his cows sleek coats and full udders.

3rd. This is quite a country for *potatoes*. The soil suits them. They sell at about an average of 50c, and pay as well as anything. We never see them plant in a *deep* furrow, but *on the surface*, or in a furrow not more than *two or three inches* deep. The results prove their wisdom. This year many of the new American varieties are being planted—Sebec, Early Gooderich, Garnet Chili, Harrison, &c., &c. There is one new kind that I think surpasses all the rest, "the Greys," as they call them here, a roughish, grey skin, white and mealy, and as sound and heavy now as if dug yesterday. Ontario planters would do well to obtain seed from this more northerly latitude.

4th. They do not cut away all the trees. By wayside, on hill sides, and almost everywhere possible, trees and shrubberies are growing. We have beauty and shade—shelter from sun and from storm. Better still, we are not parched with drouth. Often as I pass through Ontario, with a quarter or half of every farm lying in naked fallow, weeds and shrubbery mercilessly burned with fire, and the land parched with drouth, do I wish in my heart those Western men could take a July ramble through the green oases of the

EASTERN TOWNSHIPS.

Compton, May 11th, 1868.

Farm Notes.

A CORRESPONDENT, "W. B." of Home Cottage, Chingnaconsy, sends us the following communication giving the results of his own experience:

In raising grain it is of the utmost importance to adopt the best method of collecting the largest amount of manure possible on the farm itself, which is altogether cheaper and better than buying and hauling from a distance. This I have been able to accomplish to some extent by keeping and wintering as many cattle as I can feed, by raising turnips, and feeding all the hay grown on the farm to my stock. Occasionally the expense may seem to exceed the profit, but in the end the plan is sure to pay. I find it advantageous to let my clover be cut only one season, and have the after grass eaten on the ground, after which the field is ploughed up and sowed with peas, to be followed with barley or spring wheat. In this way you can seed a ten acre field every year with a bushel of clover seed, costing say from five to six dollars a bushel. You get double the quantity of hay or clover from the same quantity of land; whereas by cutting meadows several years in succession you get in the second year but a poor crop, and still worse the third year. My advice is, keep ploughing and seeding down; never mind the expense; it will pay at last. My motto is to raise all I can within the farm itself, without having recourse to artificial or foreign manures.

The following report of my crops for last year may perhaps be of some interest to your readers. From twenty acres of fall wheat, 600 bushels; one acre of spring wheat, on fallow, 20 bushels; 10 acres, on stubble, 100 bushels of spring wheat. This crop was somewhat injured by the worm, and much deteriorated by an admixture of poor seed. Five acres of barley yielded 100 bushels. From fourteen acres of peas, on clover sod, I obtained 350 bushels; thirteen acres oats, top-dressed with plaster, about 30 bushels to the acre. Of turnips, in consequence of the very dry season, the crop was very light. Ten acres of a first crop of clover yielded two tons to the acre—the land being in good order and plastered. Another ten acre field, not in as good condition, produced one and a-half tons to the acre. I use plaster plentifully, applying it on a dewy morning. I generally fallow twenty acres a year. This is a 150 acre farm, of which 130 acres are cleared. In another communication I will give a report of my expenses and profits on this scale, and also some account of my early experience, and how I commenced farming in Canada.

Order and Cheerfulness.

To the Editor of THE CANADA FARMER:

SIR,—We find a class of farmers who are always grumbling and scolding, continually out of humour with everything and everybody about them. If a day is rainy or stormy they are restless and discontented, thinking it so much time lost, as though they had no mind to cultivate. Everything is hurry! hurry! hurry! from New Year's to Christmas. The work is so managed that it encroaches upon the Sabbath in different ways. The hired help comes in for a large share of his unkind words, looks and actions, while his wife and children are not neglected in his onslaught. Everything goes wrong with him; surely he must have been born on the wrong day of the week, and the wrong month of the year. The cattle are always breaking over his fences; his crops are late, and consequently light; his stock are unfortunate, or his family are subject to all the ills which flesh is heir too. Irritability seems to be a sort of second nature to him; he thinks that he could not get along without grumbling and scolding; indeed it is hard for a farmer to be cheerful and pleasant when everything is going wrong about the place. It is true there are some who have become so habitually used to confusion that it is taken quite calmly. Order would seem as much out of place with these few as a snow storm in summer.

But to a person who wants to be a successful farmer this irritation is very unpleasant; it troubles him day and night, until at last he becomes what is commonly known as "broken-down." The want of any order in their work causes a great deal of this disatisfaction and grumbling. When a farmer starts business he should make order his motto; do everything in its proper time, and much of this hurry would be avoided. Use the head more than the hands, plan the work, study the diseases of the stock, etc., and much less displeasure will follow. For if you have the satisfaction of having done your part well, i.e., everything in the right time and proper manner, then you will have less cause for discontentment. Never grumble about things which you cannot help, but resign yourself cheerfully into the hands of Providence.

It may be said that some people are naturally irritable. This is not so much the case as it is a *habit* which they do not try to break through. Now, if farmers would use their heads more and hands less, it would be better; if the work cannot be accomplished, employ more hired help; manage the work properly; superintend the labour, marketing, care of the stock, etc., then much of this confusion would be avoided. Fallows would not be neglected until it is too late to destroy weeds; haying would not interfere with harvesting; the roots would not be left until they are frozen fast in the ground.

How many young men have started on a good farm, well stocked, and have worked hard, but for lack of a little management in their business, they have no more than made a bare subsistence. Keep cool—even in summer—don't let every small inconvenience annoy you, study the cause of the annoyance, then set about remedying it, and be careful to prevent its recurrence.

Ontario. CULTIVATEUR.

Balance Sheet Addenda.

To the Editor of THE CANADA FARMER:

SIR,—In the Farm Balance Sheet I sent you, published in your issue of April 1st, you have the item "Feed" repeated. The second "Feed" should have been "*Seed*." In referring to the copy, I find the word rather blotted, and difficult to be deciphered, hence the mistake. The repairing and blacksmith's work were certainly very heavy, and I trust, nay, am sure, will be much diminished this year. Labor, &c., in preparing the land, included hired man's wages and board. I paid him as wages $150 a year; but being a married man with a family, in lieu of boarding him, I gave him $50 a year—in all $200, a cottage, half an acre of land, and some other privileges. I discharged him at the end of the year, so I shall save all, or nearly all that amount. I had all the feed to buy for the stock from the day I entered upon the farm until I gathered the harvest, except grass. I kept about 40 bushels of wheat for home use, and fed to the stock the difference of peas, oats, and barley, between what I had reaped and what I had sold. Also, the house was well supplied with vegetables from the kitchen garden, but of this I kept no account.

I had under cultivation—

Wheat	30	acres,	produced	330 bushels.
" Barley	6	"	"	150 "
Peas	6	"	"	100 "
Oats	5	"	"	80 "
Peas & Oats	2	"	"	2 tons.
Roots	2	"	"	100 bushels.
Pasture	10	"		
Garden & Orchard	4	"		
	65	acres.		

This is the extent of my cultivated land. I have since cleared seven acres. I have five acres of this in fall wheat, and shall have two acres in oats.

I have now corrected the errors, and supplied the omissions referred to by you, and hope to have the pleasure of sending you a very satisfactory balance sheet next year. ULMUS.

NOTICE TO SECRETARIES OF COUNTY SOCIETIES.—The Secretaries of County and Electoral Division Societies are requested to send without delay to Mr. Edwards, of the Bureau of Agriculture, a correct list of their officers, (President, Treasurer, and Secretary), also the names of the officers of the Township Societies associated with them, unless they have already sent in the names either to the Bureau or Board of Agriculture. An *immediate* attention to this matter is particularly desired, in order that the official list of Agricultural Societies may be completed as soon as possible.

The Canada Farmer.

TORONTO, CANADA, JUNE 1, 1868.

Monthly Fairs.

It is gratifying to find that these institutions are being established in various parts of the country, and that there is a prospect of their coming into vogue at all our leading market centres. They have many advantages. By fixing a time when cattle and other farm products will be exposed for sale, they attract buyers, and render disposal well-nigh certain. Prices are pretty sure to find their just level. Business is thus at once facilitated and regulated.

The fair also presents an opportunity for the sale of a variety of articles not strictly agricultural products. Farmers require furniture and a multitude of things which can be exhibited to view on market day, and sold. The regular merchants always expect to do a "big business" on fair days, and itinerant merchants, pedlers, and auctioneers, not to say medicine vendors, reap a fine harvest at that time.

Implement-makers have an opportunity of exhibiting the articles they manufacture to the numerous farmers brought together by the fair; and we believe a large amount of business of this kind is done where these institutions exist. They come to be township and county shows on a smaller scale, and there is often a goodly array of tools and implements on the fair ground. They also afford facilities for the exchange of seed, and for a variety of transactions best attended to when a large number of people from various localities are met in one place. Many appointments are made, and a diversity of matters disposed of on "fair day."

The above and similar advantages are not without their accompanying drawbacks. People are very apt to be imposed upon by unknown and irresponsible persons, who bring to market wares that, like the noted razors, are made to sell. These travelling merchants and auctioneers are voluble in praise of the articles they vend, and too many receive as perfectly true the statements poured forth so glibly. The utmost caution should be exercised in purchasing of such people. This is a free country, and there is no way of restraining from business the sharp practitioners now referred to. It only remains to put the public on their guard against imposition. Generally speaking, it is better to buy of an established merchant, who has a reputation to maintain, and a business to build up, and whose interest as well as duty it is to deal honourably with his customers. Unless one is a judge of goods, and feels quite sure as to their quality and value, it is a great risk to buy under the circumstances in question. Many a supposed bargain proves to be a "sell," and many an imagined cheap purchase turns out to be dear-bought experience. In this connection the public need to be warned against the unprincipled quacks who are apt to infest fairs. These beings go into affecting descriptions of the "ills that flesh is heir to," picture the pains and aches felt by the parties they address, and urge on them some nostrum which is a sure cure,—"all for the small sum of twenty-five cents." If these much-extolled specifics were harmless, the loss of money by their purchase would be an item worth considering; but in many cases they are positively injurious, and instead of curing, sow the seeds of disease. The administration of medicine requires a skilled and experienced hand. A vast amount of mischief to health is unwittingly perpetrated by dosing in the dark. People should find out what really ails them, and be sure they have got hold of the right remedy, before they venture on taking physic. It is the height of folly to swallow medicine at random, or to put health at the mercy of quacks, whose only object is to make money by the sale of their wondrous cure-alls.

Fair-days are often marked by more or less free indulgence in stimulating drinks. Old friends meet, new acquaintances are made, and alike the old and the new friendship must be cemented by "a cup o' kindness," in which, alas, an enemy lurks that "bites like a serpent, and stings like an adder." Bargains are usually so hard as to need softening by means of alcholic moisture. It is a sort of holiday time, and why not be jovial? In short, the excuses for indulgence are very plentiful on fair-day, and many who come to market sober, go home drunk. Intemperance is one of the worst evils under which the country groans, and we fear much is done to promote it at these monthly fairs. Why are men such fools as to put that into their months which steals away their brains, and not their brains merely, but their characters, their all?

It appears to us that these fairs might be made promotive of much agricultural improvement if the rights means were taken. Why could not some time be spared for a farmers' club to meet on that day? Enough time is wasted, if not worse than wasted, in the tavern and elsewhere, to suffice for this sort of thing. What useful discussions might be had about the weather, season, crops and markets, if farmers were only so disposed. Merchants, grain-dealers, and millers have their meetings from time to time; commercial men have their Boards of Trade, Exchanges, and Chambers of Commerce. Why have we not arrangements of this kind to protect and promote the farming interest? Almost every class but the agricultural understands and applies the principle of combination for the promotion of a common interest. Some departments of business owe much of their prosperity to the adoption of such measures; and we are convinced that farmers would do well to copy the example set them by men of intelligence and enterprise who move in other fields of activity.

Immigration and Colonization.

MR. JACKSON, Chairman of the Committee on Immigration and Colonization, recently submitted a voluminous report, which, after giving an historical and statistical *resume* of the subject, closes as follows :—

"The system which has been in existence for furthering and aiding immigration to Canada has not been productive of satisfactory results, neither is it, in the opinion of your Committee, adapted to be so under the law which has placed the public lands under the control of the Provincial Legislatures.

"In order to avoid a conflict of authority and to secure the efficiency of any general immigration scheme, it is necessary that there should be an understanding, and consequently co-operative action, between the General and the Provincial Legislatures. In the meantime; and before any such concurrent action can be agreed upon, your Committee recommend that such care and assistance be extended to immigrants arriving seaward, as may be necessary.

"Your Committee recommend a discontinuance of the agency at Wolverhampton, in England, and such a reduction of the staff at Quebec, Toronto, and other agencies, as can be made consistently with the recommendation in the preceding paragraph, with a view to the early re-organization of these agencies.

"As the success of the immigrant depends greatly upon his willingness and ability to adapt himself to the conditions in which success is alone to be expected, your committee suggest that great caution and circumspection should guide any public effort to induce persons to immigrate. While Canada offers health, prosperity and freedom to the industrious laborer and mechanic, she cannot safely assume any responsibility on behalf of persons whose occupations or habits have been unfavourable to self-reliance, or to the practical exercise of intelligent effort.

"Your committee have received a number of letters containing suggestions on the subject of Immigration, and offers on the part of the writers, to place their services at the disposal of the Government, as writers or lecturers on the resources of Canada, in Europe. It is not incumbent upon your committee to express any opinion in reference to the suggestions themselves, or to the gentlemen by whom they are made ; for, if the views to which your committee have given expression, in this report, are in accordance with those entertained by your honorable House, it will be the obvious duty of the Government—in conjunction with the Provincial Governments—to adapt the agencies in Canada and elsewhere to existing circumstances.

"The prospective acquisition by Canada of the fertile lands in the valley of the Saskatchewan and its tributaries, is, no doubt, interesting to thousands who propose to migrate from the mother country to one of its dependencies. In the present state of the relations between the North-west Territory and Canada, no precise plan for its settlement can be recommended, or even considered, by your Committee, but they submit that, without any unnecessary delay, so much of these lands as are fitted for agricultural purposes should be made accessible through British territory, and offered on such terms as will be attractive to a class of settlers who desire to enjoy the fruits of their industry under the security of British laws and institutions.

"Coincident with the construction of the Intercolonial Railway, a large quantity of land, hitherto inaccessible, will be available for settlement. During its progress, the laborer will earn the means of sustaining himself in the early stages of his settlement. The chief drawback to settlement hitherto has been the difficulty of obtaining employment at a convenient distance, and then of carrying produce to market over a long line of almost impassable roads. On the line, and within the influence of the Intercolonial Railroad, these difficulties will not exist ; therefore, your Committee urge upon the Government of the Dominion the necessity of co-operating with the Provincial Governments, through whose road the territory will pass, in the adoption of a well-considered and liberal policy, with regard to settlement. The Legislatures of Ontario, Quebec and New Brunswick, respectively, have passed homestead exemption laws. The former has also devoted large tracts of land for the behoof of actual settlers, in free grants of one hundred acres each, with permission to purchase an additional one hundred acres, at fifty cents an acre. Though these terms are not precisely similar to the homestead exemption and free grant system of the United States, they are presumed to be equally favorable. Your Committee doubt not that the terms will be altered or modified, should it be found in the interest of settlement to do so. The new policy, so far, appears to be liberal and progressive, and may be held as justifying a claim for an adjustment by persons in arrears to the Government on account of purchased lands in the comparatively recent settlements, but which lands, for various reasons, are of little real value.

"The mode in which the mineral lands in the Dominion are to be disposed of, and the obligations imposed by the Governments with regard to the manner of working these lands, will very seriously affect the number of mining immigrants, as well as the flow of capital necessary for the development of our mineral resources. The mode of disposing of such lands should be at once inviting and encouraging ; therefore your Committee desire to express the hope that the public policy in regard to them will be quite as liberal as that which appears to have succeeded in the United States. By the investment of capital in extracting the treasures of the mine, a consuming population necessarily follows, so that, besides giving value to that which has no value, while hidden in the earth, a home market is opened for the produce and manufactures of the country."

From the above it will be seen that the important matters of immigration and colonization are still attracting the attention of the Dominion Legislature, and that there is evidently felt to be need of modification and improvement in existing arrangements. This is well. We are persuaded that nothing is of more pressing importance just now than doing all we can to attract a hardy, industrious, thrifty population to our unoccupied lands, and for this purpose a most liberal policy ought to be adopted. Better far to err, if err we must, on the side of generosity than of parsimony.

We quite agree with the Committee that public effort to induce persons to immigrate should be put forth very judiciously. Perhaps little should be done besides giving publicity to facts relative to the country, leaving these to their natural influence. But most certainly information should be as widely diffused as possible. We are in favor of spreading information not only by suitable publications, but by the living voice, if a suitable person or persons can be found to undertake a tour of lectures in the old world. But it requires a rare combination of qualities to fit a man for this work. He must know the country, understand roughing it in the bush, have some enthusiasm in regard to Canada, and be a vivacious public speaker. Such a man might do immense service in promoting immigration and colonization.

But whatever is done in the way of advertising Canada, it is of prime importance that alluring inducements to settle be offered by the Government. Our Homestead and Free Land Grant Acts are hampered with too many restrictions. Apart from the expediency of a liberal policy in itself considered, we have powerful competition to contend with. Our American neighbors have shown themselves wise in their generation in the unincumbered freeness of their land system. They have peopled their new territories in a marvellously short space of time, and augmented commerce and revenue to a degree that has paid them well indeed for the bestowal of the land on settlers. Let us imitate their example, and if possible outdo them in generosity toward the emigrant. We shall find our account in it, without fail.

Agricultural Intelligence.

The Crops.

FAVORABLE reports of the condition and promise of the crops reach us from all sections of the country. The season, though it opened unusually early, has been kept back by cool, if not cold weather. This has, however, proved no detriment, and will eventually be advantageous to field crops and fruit. Latterly an abundance of rain, with moderately warm weather, has set everything growing most luxuriantly. Pastures and meadows especially are pushing vigorously forward, under the influence of the timely showers, and there is every probability of another abundant hay crop. As specimens of the reports contained in our local exchanges, we give the following. The Belleville *Intelligencer* says :

The warm sun and genial rains are bringing on vegetation with remarkable rapidity. Nearly all the spring grain has been got in under very favorable circumstances, and the fall wheat presents a much better appearance than it did a week or two ago. A farmer of great experience told us this morning he never knew a season which promised such a bountiful harvest, and unless something untoward occurs, the husbandman will be enabled to rejoice and give thanks for barns and granaries overflowing with plenty.

And from the fruit garden of our Province we have the following report in the *St. Catharines Daily Briton* :

We are happy to announce that all kinds of crops never presented a more promising appearance than they do at present, in this neighborhood. Fall and spring grains are growing luxuriantly under the influence of the very favorable weather we have enjoyed for several weeks past. There is also every appearance of an enormous fruit crop. Apple, pear, plum, and cherry trees, are just now bursting into bloom, and will certainly yield a golden harvest, if no late frosts or other unforeseen disasters occur. Contrary to expectation, it seems probable that some of the peach trees may likewise produce some fruit, as all the buds are not winter killed. Grapes, strawberries, and other small fruits, promise heavy returns. From all parts of the Province we are constantly receiving favorable reports of the grain crops ; and the same is true of the Western States.

Dominion Ploughing Match.

THE Dominion Ploughing Match took place at Brooklin on the 21st of May. There were seventy-two entries, and the number of spectators present was estimated at from 5,000 to 6,000 ; but the latter part of the day was wet and uncomfortable, which no doubt considerably diminished the attendance of visitors. The ploughing commenced about ten o'clock in the forenoon; the field selected for the trial belonged to Mr. John Camplin, and was situated about a mile and a half from Brooklin. It contained twenty-four acres, and about one-third of an acre was allotted to each competitor. The time allowed was 4 hours 8 minutes to first-class men, and 3 hours 10 minutes to other classes. The time seemed rather short, and some did not get through their task. There was some excellent work displayed by others besides the successful competitors. The land, however, was not in first-class condition, the soil being too tender. On the ground there was an ox team in harness, which attracted much attention; so much so, indeed, that the numbers gathering around caused the animals to be somewhat frightened.

Among the visitors present were both the members for South Ontario, T. N. Gibbs Esq., and Dr. McGill. The occasion of so large a concourse of people gave an excellent opportunity for the display of agricultural implements and other matters of interest to farmers. Reapers and mowers were exhibited by Messrs. Massey, of Newcastle, Hall of Oshawa, and Brown, of Whitby. The new style of Reaper, known as the Marsh Harvester, and recently described in the CANADA FARMER, was also shown by Messrs. Paxton, Tate and Co., of Port Perry. There were besides a number of smaller articles, such as cheese vats, horse rakes, Thomas' bee hives, &c.

The ploughs used were generally the iron plough, and proved themselves in good hands to be thoroughly efficient implements. The following was the award of prizes :

First-class Men—Simpson Rennie, Scarborough, 1st prize, $100—given by the Hon. the Speaker, and members of the House of Commons.

Adam Hood, Scarborough, 2nd prize, $50—given by the members of the Commons and Local Legislature for North and South Ontario.

William Hood, Markham, 3rd prize—A twenty-dollar plough, the gift of Messrs. Brown & Patterson, together with $20 added.

James Forest, West Whitby, 4th prize, $15.

Andrew Hood, Scarborough, 5th prize, $10.

Second-class Men—William Patton, Scarborough, 1st prize, a seed drill, valued at $80, the gift of Mr. Glen of Oshawa.

John Morgan, Markham, 2nd Prize, a pair of harrows, valued at $15, the gift of Messrs. Walters & Brady, Audley, together with $20 added by the Municipal Council of East and West Whitby.

John Burns, West Whitby, 3rd Prize, $25 worth of agricultural Implements, the gift of Messrs. Whiting & Cowan, Oshawa, being one of every article manufactured by that firm.

Andrew Davidson, Pickering, 4th prize, a spring bar saddle, valued at $12, the gift of Mr. John Dale, of Brooklin.

John Hickingbottam, Pickering, 5th prize, $8.

First-class Boys, 18 and under—John Gowie, Pickering, 1st prize, $20, the gift of the Hon. John Simpson.

William Leask, Foley, 2nd prize, a pair of harrows, valued at $16, the gift of Messrs. Hepburn & Roberts, Brooklin.

John Lamb, Reach, 3rd prize, $8.

Thomas C. Pilkey, Pickering, 4th prize, a first-prize horse rake, valued at $5, the gift of A. Ketchen, Brooklin.

R. G. Ratcliff, Columbus, 5th prize, $3.

Second-class Boys, 15 and under.—George Robb, Whitby, 1st prize, a bridle and martingale, valued at $6, the gift of Mr. William Thompson, of Whitby, to which was subsequently added (after the advertisement of the premiums had been printed) a sewing machine valued at $16, the gift of Mr. G. M. Green, of Uxbridge.

J. Cawie, Pickering, 2nd prize, $5, the gift of W. S. Billings, Esq., of Whitby.

Jasen Stone, Brock, 3rd prize, a bridle and martingale valued at $4, the gift of Mr. Maybee, Brooklin.

James Lynde, Whitby, 4th prize, a bridle and martingale valued at $3, the gift of Mr. Philip, Whitby.

From the above it will be seen that Scarborough and Markham carried off the highest and best of all the valuable prizes. All the ploughing was pronounced excellent, and the judges had no easy task in arriving at a decision. Their award, however, was generally acquiesced in as satisfactory.

The judges were Messrs. Walter Daizel, Vaughan ; James Weir, Scarborough ; John Lee, Whitby ; John Hepburn, East Whitby ; William Sinclair, Whitby ; and John Whiteridge, Bowmanville.

The officers of the Whitby and East Whitby Society had no small difficulties to encounter when they undertook the enterprise of the Dominion Ploughing Match, and awarding prizes amounting in the aggregate to some $500. They may well congratulate themselves upon the abundant success which has crowned their efforts, and the general expression of of satisfaction on every side called forth by their management.

Since the above report was put in type, we have received a communication on the subject from Mr. James King, who writes in high terms of the excellence of the work, the competence and fairness of the judges, and the general success of the match. He adds that Scarboro offers to subscribe the necessary funds for the next Dominion Ploughing Match, and thinks no Township better suited for the trial or able to acquit itself more honorably in the competition. It is also proposed, he says, to institute "a Dominion Ploughing Society, with officers and directors in different counties."

Wool Exposition.

WE have received the following circular in reference to a proposed Exhibition of Wool and Woollen fabrics, to be held in Chicago in the month of August next. The matter will doubtless be of interest to our wool-growers and manufacturers, though we do not understand that the competition is open to Canadians.

At a meeting of the Woollen Manufacturers' Association of the Northwest, held at Chicago, Feb. 15, 1868, it was decided to hold an Exposition of Wools and Woollen Goods at Chicago, on Tuesday, Wednesday and Thursday, Aug. 4, 5, and 6, 1868. It is the design of the Exposition to make such an exhibition of all the classes of wools produced in the West, and of all the manufactured products of these wools, as shall fitly show the present magnitude of the wool and woollen interests of the West, and shall best advance their future prosperity, and by bringing together representatives of the wool-growers and wool-workers to enable them to harmonize conflicting views and to agree on such course as shall best advance the interest of both parties. It will also prove of great advantage to parties exhibiting, in affording opportunities for effecting sales.

There is every indication of a very large and fine exhibition of wool products. Manufacturers have also been requested to exhibit specimens of the wools of their several localities as prepared for market, and also when scoured. But for the main display of wools we must look to the wool growers. The Exposition Committee, in accordance with a resolution adopted by the Association, extend a cordial invitation to the wool-growers of the United States, especially of the Northwest, to exhibit specimens of all classes of wools. Where it is practicable, it is requested that entire fleeces be sent, but where this is impracticable, samples will be gladly received.

Every facility will be granted exhibitors of wools to enable them to display their goods to the best advantage. It is requested that the delegates appointed by the Northwestern Wool Growers' Association, to attend the Exposition, and delegates from or officers of the National and State Wool Growers' Associations, will assist in the selection of a Committee to properly classify and arrange the wools exhibited.

An effort will be made to have goods intended for exhibition shipped over the various railroads free of charge. If addressed to the Secretary of the Association, Jesse McAllister, 2, 4 and 6, Rush Street, Chicago, they will be taken to the place of exhibition and properly placed by the Committee, free of charge.

The diploma of the Association will be awarded to the exhibitors of the best and largest displays of each of the following classes of wool : Broadcloth, delaine and combing ; of the best collection of samples of each of these classes ; of the three unwashed fleeces (in each class) best "put up" for market ; of the three best "put up" washed fleeces (of each class) ; of ram's fleece (in each class) of greatest market value ; of ewes' fleece (in each class) of greatest market value ; and of any other exhibition of peculiar merit.

The breeders of the various breeds of sheep are requested to exhibit engravings or photographs of their stock.

Parties desiring to exhibit wool are requested to send statements of the number and kind of fleeces or samples they propose exhibiting, to G. E. Morrow, Office of *The Western Rural*, Chicago, Ill., to whom all correspondence concerning the wool department of the Exposition may be addressed.

Sheep and Shearing Exhibition.

THE principal feature in the celebration of the Queen's Birthday, at Hamilton, on the 25th ult., was the Sheep and Shearing Exhibition, conducted by the City and County Agricultural Society. This, the fourth occasion of the kind, has been a splendid success, drawing competitors from neighbouring counties, to a considerable distance. The following is the Prize List :

CLASS I.—14 ENTRIES.

Best Leicester Ram, aged, Wm. Douglas, Onondaga township, county of Brant.
2nd do., N. & B. Barker, Paris.
3rd do., Wm. Cleland, Glanford.
Best yearling do. do., Wm. Douglas, Onondaga.
2nd do. do., Peter Grant, Barton.
3rd do. do., Wm. Cleland, Glanford.

The show of Leicester rams was particularly creditable to Mr. Douglas, who was the ewe breeder of Messrs. Barker's ram that took the second prize ; also of Mr. Cleland's, that took the third prize, as well as of his own, that took the first prize.

CLASS II.—7 ENTRIES.

Best Cotswold Ram, aged, F. W. Stone, Guelph.
2nd do., Joshua Freeman, Wellington Square.
3rd do., J. L. Harming, Flanders West.
Best yearling Cotswold ram, F. W. Stone, Guelph.
2nd do., Thomas Blanchard, Nelson.

CLASS III.—10 ENTRIES.

Best Lincoln Ram, J. T. Nottle, Binbrook.
2nd do. do. do.
3rd do. do. do.
Best yearling Lincoln ram, John Walker, East Flamboro.
2nd do. Peter Grant, Barton.
3rd do. J. T. Nottle, Binbrook.

CLASS IV.—5 ENTRIES.

Best Southdown ram, John Renton, Glanford.
2nd do. James Smith, Ancaster.
Best yearling Southdown ram, F. W. Stone, Guelph.
2nd do. Robert Shaw, Glanford.

CLASS V.—5 ENTRIES.

Best Merino ram, W. Howing, East Flamboro.
2nd do. A. Binkley, Glanford.
3rd do. Thos. Shaw, Glanford.

CLASS VI.—11 ENTRIES.

Open to all other classes—sweepstakes.

Best ram, any age or breed, F. W. Stone, Guelph.
2nd best do. do., J. T. Nottle, Binbrook.
3rd do. do., Joshua Freeman, Wellington Square.
4th do. do., Wm. Douglas, Onondaga.

CLASS VII.

Best fleece, according to value, Peter Grant, Barton.
2nd do. do., J. T. Nottle, Binbrook.
3rd do. do., Wm. Douglas, Onondaga.
4th do. do. John Walker, East Flamboro.

Sheep and fleece unwashed, and shown on the ground.

SHEEP-SHEARING.

Best shearer on sheep of any age, John Gill, of Exeter village, county of Huron.

AGED SHEEP.

1st, W. Hawkins, township of Metcalfe.
2nd, John Wass, Paris village.
3rd, Nicholas C. Ford, Glanford.
4th, — Scott, Binbrook.

YEARLING SHEEP.

1st, Joseph Alton, of Nelson township.
2nd, James Ford, Glanford.
3rd, Edward Lavis, Hamilton.
4th, Wm. Milne.

Officers of Agricultural Societies.

SOUTH RIDING OF BRUCE.—President, Richard Rivers, Brant; 1st Vice-President, Nathan Lines, Brant; 2nd Vice-President, Alexander Gibson, Culross; Secretary, William Fraser, Walkerton. Directors :—Thomas Inglis, Carrick; P. M. Shannon, Carrick; W. Clark, Greenock; P. B. Brown, Culross; P. Reid, Kinloss; W. Withers, Kincardine; J. D. Parsills, Carrick; Treasurer, James Waterson, Walkerton.

☞ During the month of April nearly 5,000 cattle were exported from Canada to Buffalo, the duties on them footing up $19,000.

MAINE AGRICULTURAL STATE FAIR.—The Trustees of the Me. State Agr. Society have decided to hold the State Fair in Portland, beginning on Tuesday, Sept. 29, and to continue four days. The Cumberland Co. Agr. Society and the Portland Horticultural Society will unite, and thus combined the Fair must be magnificent.

SHORT-HORN BULL "PRINCE OF SOLWAY."—We learn that this promising Durham bull has been sold by Mr. John Snell to Mr. Lawrence Naismith, of Ramsay. It is confidently expected that he will prove a valuable addition to our Canadian Short-Horns. He is seven months old, and was sired by imported "Baron Solway," (45) dam "Blanche," by imported "Prince of the West," (588).

EXCHANGE OF SEEDS WITH RUSSIA.—The Scientific Committee of the Ministry of Domain, at St. Petersburg, have requested Mr. A. Kirkwood, of the Crown Lands Department, to send them a few pounds of the seed of the Canadian water-rice, for the purpose of making the experiment of growing it in the north of Russia. An exchange of seeds between Canada and Russia, such as Mr. Kirkwood has been endeavouring to effect, would produce important results in the agriculture of both countries, as their climatic range is very large, and somewhat similar.

AGRICULTURAL OPERATIONS.—The Montreal *Telegraph* says a friend, who has been travelling through part of the State of New York, says that field operations are considerably behind those in the neighbourhood of Montreal. A great demand, however, exists for milch cows, American buyers being anxious to purchase in Canada to supply the demand in New York State. A few days ago seventy head of prime milkers from the Upper Ottawa were taken over, and two car loads were sent from Smith's Falls. The prices obtained were above the average of late rates by from thirty to forty per cent.

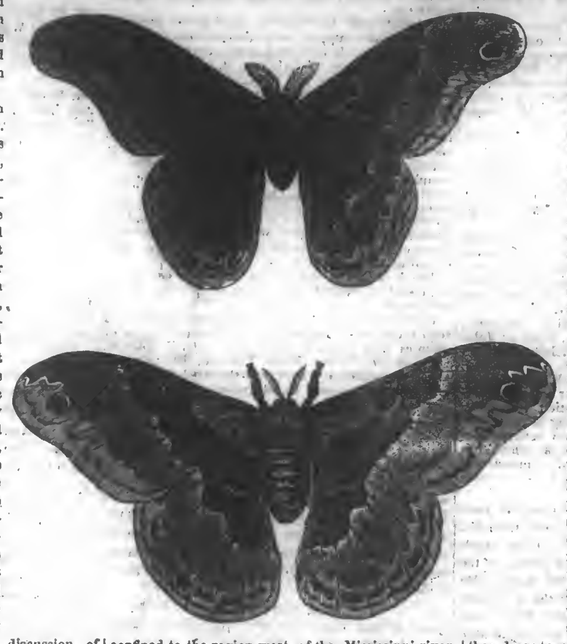
Entomology.

Entomological Report.

FIRST ANNUAL REPORT ON THE NOXIOUS INSECTS OF THE STATE OF ILLINOIS, by Benj. D. Walsh, M. A., Acting State Entomologist. Chicago: 1868.

We were quite agreeably surprised at the receipt of the above Report, as we understood that the appointment of a State Entomologist in Illinois had fallen to the ground through some strange blundering and misunderstanding. Such, indeed, was the case; but through the kindly intervention of the State Horticultural Society, Mr. Walsh was induced to go on with his valuable labors, as if the appointment had actually taken place, trusting that, when the Legislature next meets, they will approve of the course he has taken, and vote him the proposed salary. From all that we can learn we have little doubt that Mr. Walsh's expectations will be verified, and that he will receive a certain though tardy recompense for his labors.

The Report before us opens with an introductory chapter, in which Mr. Walsh relates all the circumstances connected with his quasi-appointment, and the manner in which he was induced to go on with his work, defending himself from any possible charge of taking too much upon himself, and discharging duties that he had no right to undertake. He closes the chapter with an account of the mode in which he intends to pursue his Reports, viz., "in such language as will be intelligible to any one who has had a good common school education," except that, after giving the English names of insects, he will add the scientific names in a parenthesis. Thus they will be adapted to the farmers and gardeners for whom they are intended, and not be suited only to scientific men or those of more than average acquirements, as is too often the case in works on Natural History and kindred subjects. Owing to the peculiar circumstances under which this first report was drawn up, no account is given of insects injurious to field crops, reference being only made to such as particularly come in the way of gardeners and fruit-growers; a discussion of these, however, is generally useful, for farmers, if they are not, ought certainly to be fruit-growers and gardeners also. The first insect taken up is the Grape Curculio, a small snout-beetle that has proved eminently destructive in Kentucky, Ohio, and Illinois. Though long known in its perfect state, Mr. Walsh gives here the first account of its earlier existence and full natural history; it has never, so far as we are aware, been taken in Canada. Another vine-insect is next discussed, the grape-leaf Gall-louse; this insect particularly affects the Clinton, Delaware, and a few allied varieties of grapes, causing much injury to the leaves by producing on their under side "immense numbers of green fleshy excrescences about the size of a small pea." A remedy for the "Rose-bug" (which we mentioned last year as being very troublesome near Oakville, Ont.) is the subject of Chapter III: the remedy is to grow a Clinton vine in the neighborhood of choice varieties of grape, as the insect has the bad taste to prefer the Clinton, and will desert all others for it; then, when collected thus on one vine, jar them off and kill them in any convenient way, with hot water, for instance. The next chapter gives an account of a Borer, similar to the peach-tree borer, that attacks the roots of the vine, and is the produce of a small clear-winged moth (*Ægeria*). The six following chapters are taken up with various insects that prey upon the fruit, leaves, and bark of apple-trees; among these we may particularly draw attention to the valuable account of the only too familiar "Oyster-shell Bark-louse." Three more chapters are occupied with as many destroyers of plums, viz., the terrible Curculio, the Plum-gouger—a somewhat similar insect to the foregoing, that makes round holes in the fruit, instead of crescents, and which was discovered by Mr. Walsh last year,—and the Plum-moth, another discovery of our author's, whose habits in the larval state are apparently similar to the others referred to. The Report closes with a long account of the ravages in various quarters of what is justly named "The Hateful Grasshopper," (or rather, we should say, Locust). This insect is confined to the region west of the Mississippi river, where it fulfils all the accounts given us of its cousins in eastern lands; it chiefly differs from our common grasshopper in its superior length of wing, and consequent powers of flight. The Report is illustrated, we should mention, by a plate containing figures of the more newly discovered insects.



In concluding this rather lengthened notice, we would express the hope that this is but the first of a long series of useful Reports by Mr. Walsh, who is so well qualified to produce them, and that his State Legislature will ere long recognize that in his case decidedly "the laborer is worthy of his hire."

Caterpillars on the White Cedar.

HEDGES of White Cedar form a charming feature in many gardens in and about Toronto, and notably in the grounds of Mr. Leslie's Nursery establishment on the Kingston Road; but mere beauty, alas! affords no protection against the spoiler, and even here we find growth and verdure marred by the unsparing insect. Some twigs from Mr. Leslie's hedges have recently been sent us, which sadly exhibit the destructiveness of these tiny ravagers. A minute dirty green caterpillar, with a black head and sixteen legs, has been busily at work mining into the leaves, and eating away all the green pulpy matter. A countless number of these insects soon give a blighted appearance to a once lovely hedge, and make it look as if a fire had passed through it. The mining habit of these caterpillars renders ineffectual any outward application of soap suds, lime, or other ordinary remedy; there only remains then the cutting off and burning of all infected parts. The caterpillar will turn by and by into a tiny moth of the family *Tineidæ*, of what exact species we are not yet aware.

Singular Cocoons.

A LADY sends us from Mimico two cocoons attached to a twig of lilac, accompanied by the following explanatory note:

"Enclosed you will find two specimens of Cocoons, yearly found at the bottom of a lawn, and always fastened on a white lilac bush, dangling in every storm and breeze during the whole winter. Please tell us all about them." The singular cocoons sent us by our fair correspondent, and which we were glad to receive, are specimens of the produce of one of our native silk-producing moths—the "Promethea Emperor Moth" (*Callosamia promethea*, Drury). From the eggs of this insect are hatched out in early summer a brood of bluish-green caterpillars, which come to their full size of about three inches in length, and half an inch in diameter, during the month of September. They are then very handsome, the body being adorned with a number of rows of small warts, some of which are of a bright coral-red colour, others deep blue, while one long wart is bright yellow. They feed upon the leaves of cherry, ash, sassafras, and probably some other trees. When they have attained to maturity as caterpillars, they wander off to find a suitable tree on which to form their cocoons, and pass the winter. Their mode of doing this is very curious; they select a leaf of suitable size, and fasten it securely to the twig from which it is growing by twisting silken threads around the stem and twig; then they draw together the opposite edges of the leaf, and in the hollow space thus formed construct their tough silken cocoons. This leaf, of course, withers in due time, but is prevented from falling, like the rest by its silken fastenings, and remains all through the winter dangling in mid-air as described by our correspondent. Its resemblance to an old dry leaf is no doubt a great source of protection to the snugly-enclosed chrysalis within, and accounts for the strange mode of construction. In the following June the moth comes out, and is a large and handsome object. The illustrations annexed (taken from Harris) afford an excellent representation of the size and appearance of the insect; the two sexes differ so much from each other that they might easily be mistaken for different species; the male is the smaller specimen, with deep black wings, while the female is larger, and of a reddish brown colour.

PRIVET MOTH.—We have received from Alva Rose, of Matilda, a fine specimen of the chrysalis of the Privet or Lilac Sphinx, (*sphinx cinerea*). It is one of our largest insects, feeding on the privet, lilac, or ash. Our readers will find a brief notice of the moth in the CANADA FARMER for Oct. 15th, 1866, Vol. 3, page 309.

Fruit Growers' Association.

PURSUANT to notice and in accordance with the provisions of the new Agricultural Bill, a meeting was held in Hamilton on the 15th of May to re-organize the Fruit Growers' Association. There was a large attendance of gentlemen from various parts of the Province. The chair was occupied by W. H. Mills, Esq., and in the unavoidable absence of Mr. Beadle, Mr. W. Craigie was appointed Secretary for the occasion.

The President explained the object for which the meeting was called, viz:—to consider and adopt a constitution and by-laws for the government of the society. The President then read a draft of constitution, clause by clause, which was adopted, as follows:—

CONSTITUTION.

Art. 1st. This Association shall be called the "Fruit Growers' Association of Ontario."

Art. 2nd. Its objects shall be the advancement of the science and art of fruit culture, by holding meetings for the exhibition of fruits, and for the discussion of all questions relative to fruit culture, by collecting, arranging and disseminating useful information, and by such other means as may from time to time seem advisable.

Art. 3rd. The annual general meeting of the Association shall be held at the place, and during the same time, as the exhibition of the Agricultural and Arts Association is being held, in each and every year. Two other general meetings shall be held in each year, at such time and place as shall be designated by the Association.

Art. 4th. The officers of the Association shall be composed of a President, Vice-president, a Secretary, Treasurer, and nine Directors.

Art. 5th. Any person may become a member by an annual payment of one dollar, and a payment of ten dollars shall constitute a member for life.

Art. 6th. The constitution may be amended by a vote of a majority of the members present at any regular meeting, notice of the proposed amendments having been given at the previous meeting.

Art. 7th. The said officers and directors shall prepare and present to the annual meeting of the association a report of their proceedings during the year, in which shall be stated the names of all the members of the Association, the places of meeting during the year, and such information as the Association shall have been able to obtain on the subject of fruit culture in the Province, during the year. There shall also be presented at the said annual meeting a detailed statement of the receipts and disbursements of the Association during the year, which report and statement shall be entered in the journal, and signed by the President as being a correct copy, and a true copy thereof, certified by the secretary for the time being, shall be sent to the Commissioner of Agriculture, within fourteen days after the holding of such annual meeting.

Art. 8th. The Association shall have power to make, alter, or amend by-laws for prescribing the mode of admission of new members, the election of officers, and otherwise regulating the administration of its affairs and property.

BY-LAWS.

1st. The President, Vice-President, and Secretary-Treasurer shall be ex-officio members of all committees.

2nd. The Directors may offer Premiums to any person originating or introducing any new fruit adapted to the climate of the Province, which shall possess such distinctive excellence as shall in their opinion render the same of special value; also, for essays upon such subjects connected with fruit growing as they may designate under such rules and regulations as they may prescribe.

3rd. The Secretary shall prepare an annual report, containing the minutes of the proceedings of meetings during the year, a detailed statement of receipts and expenditures, the reports upon fruits received from different localities, and all essays to which prizes have been awarded, and such other information in regard to fruit culture as may have been received during the year, and submit the same to the directors or any committee of directors appointed for this purpose, and with their sanction, after presenting the same at the annual meeting, cause the same to be printed by and through the Publication Committee, and send a copy thereof to each member of the Association, and to the Commissioner of Agriculture.

4th. Five Directors shall constitute a quorum: and if at any meeting of Directors there shall not be a quorum, the members present may adjourn the meeting from time to time, until a quorum shall be obtained.

5th. The annual subscription shall be due in advance at the annual general meeting.

6th. The President (in or case of his disability the Vice-President) may convene special meetings at such times and places as he may deem advisable, and he shall convene such special meetings as shall be requested in writing by five members.

7th. The President may deliver an address on some subject relating to the objects of the Association.

8th. The Treasurer shall receive all moneys belonging to the Association, keep a correct account thereof, and submit the same to the Directors at any legal meeting of such Directors, five days' notice having been previously given for that purpose.

9th. The Directors shall audit and report all accounts, which, when approved of by the President's signature, shall be submitted to and paid by the Treasurer.

10th. It shall be the duty of the Secretary to keep a correct record of the proceedings of the Association, conduct the correspondence, give not less than ten days' notice of all meetings to the members, and specify the business of special meetings.

11th. The Directors, touching the conduct of the Association, shall at all times have absolute power and control of the funds and property of the Association, subject, however, to the meaning and construction of the constitution.

12th. At special meetings no business shall be transacted except that stated in the Secretary's circular.

13th. The order of the business shall be—1st, Reading of Minutes; 2nd, do Directors' Reports; 3rd, do Treasurer's do; 4th, do Prize Essays; 5th, President's Address; 6th, Election of Officers; 7th, Miscellaneous Business.

14th. These by-laws may be amended at any general meeting by a vote of two-thirds of the members present.

15th. Each member of the Fruit Committee shall be charged with the duty of accumulating information touching the state of the fruit crop, the introduction of new varieties, the market value of fruits in his particular section of country, together with such other general and useful information touching fruit interests as may seem desirable, and report in writing to the Secretary of the Association, on or before the fifteenth day of September in each year.

16th. Whereas the President, or Vice-President, and Secretary, as ex-officio members of the Board of Directors, and of all Committees, should be present at all meetings, wherever they may be holden, their reasonable travelling expenses shall be provided from the funds of the Association.

17th. The annual meeting of the Association shall be held on some evening during the exhibition week, to be fixed by the Directors after consultation with the Board of Agriculture and Arts, at which meeting the President may deliver his annual address, and essays on fruit culture be read.

OFFICERS OF THE ASSOCIATION.

The following gentlemen were appointed office-bearers:—President, William H. Mills, Hamilton; Vice do J. C. Rykert, St. Catharines; Secretary-Treasurer, D. W. Beadle, St. Catharines.

DIRECTORS.—Judge Logie, Hamilton; George Leslie, Toronto; John R. Martin, Cayuga; Lewis Springer, Barton; Charles Arnold, Paris; William Saunders, London; Rev. R. Burnet, Hamilton; Levi Lewis, Ontario; A. M. Smith, Grimsby.

FRUIT COMMITTEE.—John A. Bruce, Hamilton; Chas. Arnold, Paris; A. M. Smith, Grimsby; George Leslie, Toronto; A. Leslie, London; David Coldwell, Galt; William Sanderson, Brantford; John Freed, Hamilton; W. Eccles, St. Catharines.

PUBLICATION COMMITTEE.—Judge Logie, Hamilton; Oliver T. Springer, Wellington Square; A. Macallum, M. A., Hamilton; William Craigie, M. A., Hamilton.

Before adjourning, it was resolved, on motion of Mr. Smith, seconded by Mr. Eccles, that the thanks of the Association be given to J. C. Rykert, Esq., M. P. P., for his zealous exertions in promoting the passing of the Agricultural Bill.

Hamilton Hortioultural Society.

WE have received a pamphlet containing the Constitution, By-Laws, and Eighteenth Annual Report of this efficient and flourishing Society, also the prize list for 1868. The condition of its affairs will be best exhibited by the Annual Report, which is a model of brevity, and the Treasurer's account, both of which we subjoin. This Society holds three exhibitions in the year: the first, May 25th, the second, July 1st, and the third on the Tuesday prior to the Provincial Exhibition.

EIGHTEENTH ANNUAL REPORT.

The Board of Directors, on retiring from office, would congratulate the members on the continued prosperity of the Society.

During the past most unfavorable season the three exhibitions were, on the whole, very successful, and the attendance on the part of the public was unprecedentedly large.

A reference to the Treasurer's report, which is herewith submitted, will show that a respectable balance of cash remains on hand after paying all the expenses of the year.

The Society's diploma to the professional gardener and to the amateur who should gain the greatest number of prizes during the season, in their respective classes, were awarded to Mr. William Hill and Mr. James Webster; the latter is also entitled to hold the Craigie Medal for the ensuing year.

The Office-Bearers and Directors will be glad to furnish any information asked for, by members, concerning the affairs of the Society.

Hamilton, 1st Feb., 1868.

J. A. BRUCE, *President.* JAMES ROBB, *Secretary.*

Save Your Plums.

To the Editor of THE CANADA FARMER:

SIR,—To those of your readers who are anxious to secure a good crop of plums against that incorrigible pest, the Curculio, permit me to state a successful method I have pursued for the last five years, although by no means new as a remedy. It is well known by some and pursued by others, yet there is not that strict attention paid by the majority of people who own a plum tree to secure success. I have observed some of my neighbours take the precautionary measure of jarring their trees, yet still allow the fallen plums to remain upon the ground. Now, this is a fatal mistake. Nearly all of these plums contain worms, which, during the season, are changed to Curculio, remain dormant till the following season, then make their appearance in great numbers, to the amazement and disgust of the person who fancied he had done them "brown" the year before. The way I pro-

ceed is this: I saw off a nearly horizontal limb, if such can be found, leaving a stump of three or four inches upon which to operate; then secure a pretty heavy wooden mallet, having its head covered with an elastic cushion, then two cotton sheets of six by twelve feet each, to two sides of which I tack strips of lath so that it enables me to lay them under each tree at full length adjoining each other, thus covering a space of twelve square feet, the whole being easily gathered up and removed to any tree. So armed, I may be seen during the growing season, from the time the young fruit attains the size of a small pea, "just at peep o' day," spreading these sheets beneath my plum trees, and then with a quick sharp strike against the stump of the sawed limb, with the aforesaid battering ram, I bring the enemy to bay. No quarter is ever asked or given. Under the power of such a storm, after the first few mornings the enemies' numbers grow small and by degrees beautifully less, until at length the war cry of the last "Mohegan" sounds a solemn dirge in the dewy morn. The secret is, by surprising the enemy so early in the morning, you have him at a disadvantage; for then his wings and joints are stiff, his powder damp, he falls easily into your bags; when there he looks (do not mistake him) like a dead plum bud. Now, good reader, if a little lassitude prevents your getting up with the lark, you will never secure a glorious sight of purple and golden plums after the above fashion, unless, indeed, you are fond of hogs, for they, if allowed to roam among your trees, will eat the wormy fallen fruit as soon as dropped, and thus the year following there will not be quite so many Curculio, and perchance, from paucity of their numbers, not quite able to puncture all your plums, you may have the felicity of pointing to a few stray fruits; you will at the same time have the gratification of seeing your soil cultivated without a ploughshare. This, to a man of taste, would scarcely be considered scientific. A few words more; the wind blows your plum trees at times severely, without dislodging the little "Turk;" so that no mere shaking with the hands will accomplish the object sought; it must be a quick, decisive jar. Destroy all plums as soon as fallen, and enjoy the fruits of your labour as I have done. Try it; you will come to learn that it is not half the labour your fancy painted it.

FRUIT GROWER.

Hamilton, 9th May, 1868.

Questions on Pear Culture.

To the Editor of THE CANADA FARMER:

SIR,—Will you be kind enough to answer the following questions on pear culture:

1. What kind of soil, cultivation and manure, are best adapted for the pear?
2. Which varieties are least liable to disease?
3. Which variety of the quince is best adapted for dwarfing the pear?
4. Which would you recommend as the best six kinds of standard pears; two summer, two fall, and two winter varieties?
5. Are there any varieties of the pear adapted for cultivation on the thorn stock?

W. HAWTHORN.

St. Marys.

ANS. 1.—A deep rich loam, or clay and loam, is the best soil for the pear. Mellow cultivation and well-rotted barnyard manure are the best appliances for it.

2. This question is difficult to answer. All varieties are more or less liable to the blight, a mysterious affection for which, so far as we know, there is no remedy. Blight and winter-kill are the two banes of pear culture in this country.

3. The Angers quince.

4. Tastes differ, and there is no infallible standard of excellence; the following, however, would make a good collection: Dearborn's Seedling, Bartlett, Flemish Beauty, Beurre d'Anjou, Beurre Diel, and Vicar of Winkfield.

5. Almost any variety of pear will unite with the thorn stock, but we do not know of any special advantage there is in using it in preference to the natural root. It will not dwarf the pear; the quince is the only stock used for this purpose.

Poetry.

The Waning Moon.

BY WILLIAM CULLEN BRYANT.

See where, upon the horizon's brim,
Lies the still cloud in gloomy bars,
The waning moon, all pale and dim,
Goes up amid the eternal stars.

Late, in a flood of tender light,
She floated through the ethereal blue,
A softer sun, that shone all night
Upon the glittering beads of dew.

And still thou wanest, pallid moon!
The encroaching shadow grows apace;
Heaven's everlasting watchers soon
Shall see thee blotted from thy place.

Oh, night's destroyed and crownless Queen,
Well may thy sad expiring ray
Be shed on those whose eyes have seen
Hope's glorious visions fade away.

In thy decaying beam there lies....
Full many a grave on hill and plain,
Of those who closed their dying eyes
In grief that they had lived in vain.

Another night, and thou among
The spheres of heaven shall cease to shine,
All rayless in the glittering throng,
Whose lustre late was quenched in thine.

Yet soon a new and tender light
From out thy darkened orb shall beam,
And broaden till it shines all night
On glistening dew and glimmering stream.

The Household.

Home Influence of Country Life.

AMONG the chief peculiarities belonging to a country life may be placed that home feeling which has the power, through the whole course of after years, to bring back the wandering affections, and centre them in one point of space—one point of importance to a very limited portion of the community indeed, but a portion consisting of our nearest and dearest connections. In towns there can be comparatively little of this feeling. A man steps out of his door immediately upon common ground. The house he lives in is precisely like his neighbor's, one of a number, which he returns to without attachment, and leaves without regret. But in the country, not only the grass we tread on, the fruit on the trees, the birds that sing above our heads, and the flowers that bloom beneath our feet, but the very atmosphere around us seems to be our own. There is a feeling of possession in our fields, our gardens, and our home, which nothing but a cruel separation can destroy; and when absent far away in foreign lands, and exiled from that home perhaps forever, we pine to trace again the familiar walks, and wonder whether the woods and the green lawns are looking the same as when they received our last farewell. In the haunts of busy life the music of our native stream comes murmuring again upon our ear; we pause beneath the cage of the prisoned bird, because its voice is the same as that which delighted us in childhood; and we love the flowers of a distant country when they resemble those which bloomed in our own.

And all this has a higher moral significance and influence which have often restrained the tempted, or restored the lost to virtue and peace. There are other wanderers besides those who stray through foreign realms—wanderers from the ways of God. Perhaps such may have spurned the restrictions of parental authority, and cast away the early visitations of a holier love; but the home feeling, which neither change of place nor of character can banish from the heart, renews the memory of social ties, and draws back the exiled soul to the deserted hearth. Along with that memory, associated with the soothing affection which the self-banished has lived to want, and the wisdom of sage counsel which experience has proved true, the tide of conviction rushes in upon the burdened heart, and the prodigal, rousing himself from the stupor of despair, exclaims, "I will arise and go to my father!" Parents, we counsel you to make the most of this influence; believe that it is more important to make your children's home lovely and pleasant than to render your farms ever so productive; and young people, who have the privilege of such a haven of affection and security, cherish the love of home as your most precious talisman and treasure.

☞ Those who boast of plain speaking generally like it only in themselves.

☞ A desire to say things which no one ever said makes some people say things which nobody ought to say.

THE OPEN FIRE.—"I am a firm believer," says Dr. Cuyler "in the moral and spiritual influence of an *open fire*. To make home attractive, there must be somewhere in the house a common family rendezvous; and that ought to present a more radiant attraction than a black hole in the floor, through which hot air pours forth from a subterranean furnace. Men will fight for their altars and their firesides; but what orator ever invoked a burst of patriotism in behalf of stove-pipes and registers? I never cease to be thankful that I was brought up beside the hickory fire of a rural farm house."

KEEPING FURS.—The ladies are often anxious about keeping furs free from moths during the summer months. Some one advertises to send the requisite information for $1. Darkness is all that is necessary. The "Miller" that deposits the eggs from which moths are hatched, only moves in light; the moths themselves work in darkness. Hang the furs in a very dark closet, and keep the door shut; keep it always dark, and you can have no trouble. But, as closet doors are sometimes left open, the better way is to enclose the articles loosely in a paper box, put this in a pillow-case, or wrap around with cloth, and hang up in dark closet. Camphor, spices or perfumes, are of no use. Continual darkness is sufficient. And do not take out the furs in June and July to give them an "airing," for even then cometh the enemy, and it may be that in fifteen minutes after exposure, has deposited an hundred eggs. If you consider an airing indispensable, give the furs a good switching and put them quickly back.—*Country Gentleman.*

RICH WITHOUT MONEY.—Many a man is rich without money. Thousands of men with nothing in their pockets, and thousands without even a pocket, are rich. A man born with a good, sound constitution, a good stomach, a good heart and good limbs, and a pretty good head-piece, is rich. Good bones are better than gold, tough muscles than silver, and nerves that flash fire and carry energy to every function, are better than houses and lands. It is better than a landed estate to have had the right kind of father and mother. Good breeds and bad breeds exist among men as really as among herds and horses. Education may do much good to check evil tendencies or to develop good ones, but it is a great thing to inherit the right proportion of faculties to begin with. That man is rich who has a good disposition—who is naturally kind, patient, cheerful, hopeful, and who has a flavour of wit and fun in his composition. The hardest thing to get along with in this life is a man's own self. A cross, selfish fellow, a despondning and complaining fellow, a timid, care-burdened man—these are all born deformed on the inside. Their feet may not limp, but their thoughts do. A man of fortune, on the brink of the grave, would gladly part with every dollar to obtain a longer lease of life.

PREPARATION OF WHITEWASH.—Whitewash is one of the most valuable articles in the world when properly applied. It prevents not only the decay of wood, but conduces greatly to the healthiness of all buildings, whether of wood or stone. Out-buildings and fences, when not painted, should be supplied once or twice every year with a good coat of whitewash, which should be prepared in the following way: Take a clean, water tight barrel, or other suitable cask, and put into it half a bushel of lime. Slake it by pouring water over it, boiling hot, and in sufficient quantity to cover it five inches deep, and stir it briskly till thoroughly slaked. When the slaking has been effected, dissolve it in water, and add two pounds of sulphate of zinc, and one of common salt. These will cause the wash to harden, and prevent its cracking, which gives an unseemly appearance to the work. If desirable, a beautiful cream colour may be communicated to the above wash, by adding three pounds of yellow ochre; or a good pearl or lead colour, by the addition of lamp, vine or ivory black. For fawn colour, add four pounds umber—Turkish or American, the latter is the cheapest—one pound Indian red, and one pound common lampblack. For common stone color, add four pounds raw umber and two pounds lampblack. This wash may be applied with a common whitewash brush, and will be found much superior, both for appearance and durability, to common whitewash.—*Country Gentleman.*

The Apiary.

Surplus Honey.

As most bee-keepers keep bees for the sake of the honey they gather, it is well to understand how to obtain all the honey a stock will gather, more than is required for its own use, and to do so with the least annoyance to the bees. Various methods have been practised; but the most successful, up to the present time, has been by the use of surplus boxes. Time was, when the bees were destroyed to obtain their honey; but now, such instances are rare—that method being practised by those only who are ignorant of the science of bee-culture. Surplus boxes are as various in their construction as are the hives to which they are applied. Many are almost or quite worthless, the bees seldom depositing honey in them, on account of their construction or mode of application to the hive. If we consider for a moment the nature and habits of the bee, the proper method of securing a large amount of honey, and in the most convenient manner, will readily suggest itself to our minds. It should be remembered that it is the nature of bees to work in a mass, or closely connected together. It is also their nature to store the honey as near the brood as possible, and to make use of all empty combs available, in the height of the honey season. It will then be readily seen that honey boxes should be so constructed, and applied to the hive, as to allow bees an easy access, and so that the bees when in the box are still connected with the bees in the hive; and as they are always in the habit of storing the honey close to the brood, a deep or tall honey-box is objectionable. Many will have observed that when they removed a deep honey-box, and placed upon the hive shallow ones, the bees have readily gone to work. Suppose we were to place a surplus box, three feet deep, on a hive, would the bees be likely to commence work therein? Not at all; for it is their nature to commence at the top of the box, which would separate them in such a box some three feet from the main body of the bees.

It will be found, then, that the more shallow the boxes for surplus honey, the more likely the bees are to work in them. Surplus boxes should be made of thin stuff, especially the bottom board, and a free and easy entrance given. With frame hives, boxes are sometimes used without any bottoms, and placed upon the frames. Though the bees will readily enter such boxes, if shallow, still they are not tidy, nor convenient for marketing. Boxes should therefore be made of thin stuff, and the board on top of the hive, on which the boxes are placed, should be thin also, and a free entrance should be provided. The bees will then enter readily to deposit honey, and when the boxes are removed, the honey will be in fine shape for marketing. When the bees have nearly filled one tier of boxes, it is well to have other boxes made of the same size, with a like entrance through the top and bottom, and raise up the first tier, which is nearly filled, and put the empty boxes under them. The bees will then continue work down from the top tier, and fill the second tier. Boxes should also have a piece of comb put into them, when possible, as it will induce the bees to go to work.

Markets.

Toronto Markets.

"CANADA FARMER" Office, May 29th, 1868.

THE market has been very dull during the whole of last week, and prices of all articles have steadily declined.

Flour—The market has been very dull and irregular, and closes 75c lower than our last quotations. During the past few days a considerable decline in Montreal has taken place, and in consequence dealers here reduced their bids. It is doubtful if over $6.25 could have been got for No. 1 super to-day. There were sellers at $6.50 with no buyers.

Wheat.—The market has been very dull and unsettled. The demand was almost nominal. Prices have declined considerably, but in the present unsettled state of the market it is difficult to say what prices really are. The last sales of spring wheat in car lots were at $1.47. These prices were paid yesterday. It is doubtful if these sales could be repeated, buyers having reduced their bids considerably. Fall wheat sold yesterday at $1 60 and $1 65 in car lots, which were the last sales quoted. On the street market prices are as follows:—Spring, $1 40 to $1 45; Fall, choice, $1 52.

Oats—The market continues firm. Holders are asking 56c for round lots. 55c to 56c are the prices paid on the street, the latter price being generally paid in silver.

Barley—The market is dull and drooping. Car lots are offering at from 65c. to $1. A car sold at the latter price, but buyers will not generally give as much.

Peas—The market is dull and nominal; nominally worth 87c, with no sales within the past few days. Street prices 80c to 82c.

Rye—Worth on the market $1 10.

Potatoes—There is a fair supply. The current rates are 65c to 70c per bushel by the load, and 90c to $1 per bushel by the bag.

Apples—The market is dull; choice samples bring as high as $3. Dried, dull; worth $1.25 to $1.50.

Hay—As high as $21 was paid for a few loads to-day; prices ranged from $17 to $21.

Straw—Prices range from $11 to $14.

Provisions—The market is quiet, and there is nothing of interest to note. *Pork*—Mess is held at $23, with buyers at about $22. Selling in a retail way at $23 for choice. Prime extra quality held at $11. *Bacon*—Stocks very light; Cumberland selling at from 10c to 11c. *Hams*—Uncovered held at 12½c, and covered at 13½c, in retail lots. *Butter*—Market declining; dairy tub not worth more than 17c to 18c. *Cheese*—The stock is light, and good is scarce at 12c.

Montreal, May 27.—*Flour*—Superior extra, $7 90 to $8; Extra $7 70 to $7 80; Fancy, $7 40 to $7 50; Welland Canal superfine $6 75 to $6 90; Superfine No. 1 Canada Wheat, $6 75 to $6 90; Superfine No. 1 Western Wheat, $6 75 to 6 90; Superfine No. 2 Western Wheat, $6 50 to $6 60; Bag Flour, per 100 lbs. $3 35 to $3 45. *Wheat*—Canada Fall, none; Spring, $1 60 to $1 62½. Western, $1 65 to $1 70. *Oats*—Per 32 lbs, 47c to 48c. *Barley*—Per 48 lbs, $1 10 to $1 15. *Butter*—Dairy, 16 to 18c; store packed, 15c to 18c. *Pork*—Mess, $22 50 to $23 00; Prime Mess, $16 to $16 50; Prime, $15 00 to $15 50. *Dressed Hogs*—None. *Peas*—90c.

Galt, May 23.—*Spring Wheat Flour* $3 75 to $4. *Fall Wheat Flour*, $4 25 to $4 50. *Fall Wheat*, $1 60 to $1 65. *Amber Wheat*, $1 30 to $1 55. *Spring Wheat*, $1 50 to $1 55. *Barley*, 75c to 80c. *Oats*, 45c to 50c. *Peas*, 70c to 80c. *Butter*, 9c to 10c. *Eggs*, 9c to 10c. *Potatoes*, 45c to 60c.

Guelph, May 26.—*Fall Wheat*, per bush., $1 70 to $1 75. *Spring Wheat*, $1 48 to $1 53. *Oats*, 55c to 56c. *Peas*, 80c to 85c. *Barley*, $1 20 to $1 25. *Straw*, $3 to $4 per load. *Hay*, $10 to $13 per ton. *Eggs*, 10c per doz. *Butter*, 14c to 15c per lb.

Hamilton, May 26.—*Fall Wheat*, per bush., $1 58 to $1 65. *Spring Wheat*, per bush., $1 55 to $1 62. *Barley*, do, $1 10 to $1 20. *Oats*, do, 60c to 65c. *Peas*, do, 85c to 92. *Corn*, do, 65c to 70c. *Potatoes*, per bag, $1 25 to $1 50.

London.—Grain—*Fall Wheat*, per bush., $1 50 to $1 60. *Spring Wheat*, $1 40 to $1 44. *Barley*, 75c. *Peas*, 76c to 84c. *Oats*, 53c to 54c. *Corn*, 80c to 82c. Provisions—*Pork*—English prime mess, $18 50; prime mess, $14 50; light mess, $16 50; mess, $10; smoked ham, sugar-cured, 12c.

N. Y. Produce Market.—*Flour*, dull; receipts, 6,500 barrels, sales, 3,400 brls., at $8 90 to $8 60 for Superfine State and Western; $9 00 to $9 55 for common to choice extra State; $9 00 to $10 30 for common to choice extra Western; $9 60 to $13 25 for common to choice extra round hoop Ohio. *Wheat*, dull; receipts, 37,493 bush; sales of 49,000 bush., at $2 18 to $2 18 for No. 2 spring; $2 27 for No. 1 do; $2 22 to $2 23 for Nos. 1 and 2 do., mixed; $2 25 for amber Canada; $2 27 for White Michigan; $2 36 for winter red Canada, in bond. *Rye*, dull; sales, 4,000 bush. State, at $2 03, retail lots; Western, at $2 07 to $2 08. *Corn*, heavy; receipts, 134,276 bush.; sales, 133,000 bush., at $1 00 to $1 10 for new mixed Western afloat; closing at $1 09 to $1 08½; $1 16½ for old do in store. *Barley*, nominal. *Oats*, dull; sales of 26,00 bush, at 86c to 89c Western in store. *Pork*, lower, at $23 40 to $26 50 for new mess; $27 05 to $27 75 for old do. *Lard*, quiet and dull, at 18 7-8c to 19c.

THE CANADA FARMER is printed and published on the 1st and 16th of every month, by the GLOBE PRINTING COMPANY, at their Printing House, 26 and 28 King Street East, Toronto, Ontario, where all communications for the paper must be addressed.

☞ Subscription Price $1 per annum, (POSTAGE FREE,) payable in advance. Bound volumes for 1864, 1865, 1866 and 1867, may be had for $1 20 each. Subscribers may either begin with No. 1 of the present Volume, or with the first No. of any preceding volume. No subscriptions received for less than a year, and all commence with the first number for the respective years.

CLUBS will be furnished at the following rates:—

TEN COPIES for..... NINE DOLLARS.
TWENTY COPIES for..... SIXTEEN DOLLARS.
FORTY COPIES for..... THIRTY DOLLARS.
ONE HUNDRED COPIES for..... SEVENTY DOLLARS.

To Agricultural Societies ordering more than 125 copies, THE FARMER will be sent at SIXTY CENTS.

THE CANADA FARMER presents a first-class medium for agricultural advertisements. Terms of advertising, 20 cents per line space. Twelve lines' space equals one inch. No advertisement taken for less than ten lines' space.

Communications on Agricultural subjects are invited, addressed to "*The Editor of the Canada Farmer*," and all orders for the paper are to be sent to GEORGE BROWN,
Managing Director.

VOL. V. No. 12. TORONTO, CANADA, JUNE 15, 1868. POSTAGE FREE.

The Field.

Alsike Clover.

THE following is an extract from a farm journal:—

"23rd May, 1868.—Made the weekly inspection of the farm. Went first to the Colt Ground, where the span of colts, now three years old, are growing into the future team. This place consists of four acres, fenced in with Black Ash pole or log fence, so high that they cannot jump over, and so strong that they cannot break through. This is the true way to prevent colts being breachy. The pasture is very rich, and is more than will be necessary to support the colts during the season.

"I noticed the Alsike clover particularly, which is now about five inches high. It possesses one unusual peculiarity, viz., that of doing best in the holes covered or nearly covered with water during the winter and spring. No doubt this is a valuable property as compared with red clover, which will not stand such hardship. Another thing to recommend its use is, that before timothy or red clover is ripe enough to cut for hay, the top flowers of the alsike are ripe, and shed their seed, which seem to catch at once and grow, as I find vast numbers of young plants only two inches high, the result of last year's haying. Our colt pasture is an uneven piece of land, and the roots and stumps not out sufficiently to enable us to level it yet."

This property of withstanding water in the winter and spring renders it a very useful plant for undrained farms, and reminds us of the native place of the Alsike clover, which was first discovered in the ditches of the fortification of "Alsike," in Sweden.

Prolificacy of the Thistle.

To the Editor of THE CANADA FARMER:

SIR,—I have known you return your thanks for specimens of ripe strawberries, forwarded to you for trial; but the enclosed specimen of *seedling thistles* is entirely wanting in those mouth-watering qualities of which a ripe strawberry is so eminent a provocative, yet it may be of much more importance when gravely considered in its threatening aspect. My object in sending you these is to demonstrate the fallacy of Peter Shisler's assertion, published in a recent number of your journal, where he randomly asserts "Not one in a million of the seeds of the thistle grow." I have seen them so thick on ploughed ground this month that you might count fully 150 to the square foot. The bunch in the centre, with the thread around them, is just as they were lifted, and too thick to count; the others are selected of different stages of growth, to show what they are. With your permission I will give a rejoinder to Peter Shisler's letter in your next issue, over the signature "Publicola."

W. BURGESS.

Mimico, May 29th, 1868.

NOTE BY ED. C. F.—We gratefully acknowledge the compliment paid us by our correspondent in believing that we feel no "mouth-watering" after thistles, and assure him that we hold them in utter aversion. We have caused the specimen of seedlings forwarded us to be engraved life-size, to give ocular demonstration of the prolificacy of this detestable weed, and to point an argument for stirring the soil with cultivator, harrow and horse-hoe, in order to secure its destruction. It is easy to exterminate weeds in the early and feeble stages of their growth. Merely a disturbance of the soil then suffices to destroy them, whereas when once they are rooted, it is a matter of extreme difficulty to get rid of them. We hardly think there is ground for controversy between our present and former correspondent. Speaking in a general, hyperbolical sort of way, one may say that not one in a million of these seeds vegetates, for it is quite evident that only a small proportion grows, inasmuch as a single thistle plant will throw upwards of 11,000 seeds, according to the estimate of Dr. Lindley, given in our last issue, under the head of "Weeds." We cordially second the most fierce and furious crusade against them. The publication of actual experience in attempts to get rid of this troublesome pest, though the statements may sometimes perplex by their apparent contradiction, cannot fail to be of service, and ultimately lead to effective methods of destruction.

Chinese Yam.

Dioscorea Batatas

To the Editor of THE CANADA FARMER.

SIR,—Having fully investigated the character and merits of this yam, I have some positions to announce in regard to it, which I should have much hesitation about advancing, if I were not well assured of their triumphant verification by my countrymen. I assert, that this esculent, by its concentration of each useful property, transcends in importance every other edible vegetable of the earth, and that it is destined to supersede the tropical and unreliable potato in all northern climates. The combination of its admirable properties as food for man, constitute it also the most estimable vegetable boon, and the most nutritious aliment, for man and domestic stock, which God and nature, in their all-pervading beneficence and benign provision, have bestowed upon the inhabitants of our globe. I shall discuss all these points on a future occasion in the ample sense to which they are entitled. The present article is intended solely to impart such practical facts and advice in relation to the plant as will aid those who are now commencing its culture. I desire, however, to make known that there are more than fifty varieties of various colors and forms, and varying in length from seven inches to two feet.

CHARACTERISTIC POINTS.—This yam is a native of the northern limits of the temperate zone, and will flourish in the coldest regions of our country, and of the British Territories, and will endure, everywhere, the winters in the open ground. Its produce is more than double the crop of any potato, and it never rots. It will flourish best on the now useless sandy lands of New Jersey and Long Island, and of the entire coast range, and it will also succeed on any other soil but a stiff clay. It does not require replanting annually, but reproduces abundant crops from the fragments and small tubers that are left in the earth. There can be no fragment, however diminutive, that will not vegetate. From tubers, the roots attain ten to twelve inches in length, and weigh four to six ounces. From sections of the root, such as used for the regular crop, the roots attain eighteen to twenty-four inches in length, and weigh from half a pound to one and a half pounds, and often more. A plantation of this yam, is in China termed "a Permanent Magazine of Food," and the roots may be dug fresh for use daily, from early spring to winter, thus furnishing new yams continuously. It

is more palatable than the best Mercer or any other potato. Its taste and flavor are intermediate between the finest potato and arrowroot, of an exceedingly delicate farinaceous character, and like the potato, it is devoid of all insipid sweetness. It is free from any ligneous or fibrous substance, and possesses the peculiar property of not being subject to rot or decay, but will remain perfectly sound and excellent in a dry state for a year, thus rendering it exceedingly valuable for long sea voyages, and for the prevention of scurvy. It is much more nutritious than any other edible vegetable used by man, and more so than wheat or any other grain. It is the only vegetable of all the earth which combines an ample portion of Azote, the grand constituent of animal substances which impart vigor to the muscular power of man and beast; and it is by the possession of this essential equivalent in this esculent that the use of animal food is rendered unnecessary by the Chinese and Japanese nations, whose immense populations comprise nearly one-half the inhabitants of our globe.

The culture of this most estimable and productive of all vegetables, on the sandy soils of the south side of Long Island, and throughout the sandy region of the Atlantic portion of New Jersey, which are of a character precisely adapted and congenial to its growth and development, and where the crops will consequently be much greater than in other locations, must impart a value to those lands which no one has yet anticipated; and they may soon command higher rates than any of the firm soils of the north side of he Island or of the upper section of New Jersey.

PREPARATION OF THE SOIL.—The ground for planting tubers should be rendered mellow and permeable to the depth of fifteen inches, and for roots to the depth of twenty inches. Old decayed stable manure, or decayed peat or wood mould, should be mixed moderately throughout. Over-manuring is injurious, and poudrette is unsuitable.

PLANTING.—The season for planting is as soon as the freezing has ceased, and the ground has become settled.

Tubers.—These should be planted in a double row—the rows twelve inches apart, and the tubers ten inches apart in the rows.

Roots.—The sections of root should be about one and a half inches in diameter. They should be planted in a double row—the rows fifteen inches apart, and the roots at twelve inches apart in the rows.

There is no plant whose culture is more simple and easy than that of this yam.

Its extensive cultivation promises to our country a vast and inexhaustible resource, derived from such soils as have hitherto been most unproductive and unpromising. It will supersede and far more than replace the failing and uncertain crops of the potato, with the addition of this potent and comprehensive fact, that this esculent will succeed and yield ample and reliable crops throughout all the northern sections of the country, where the potato never has been, and never can be grown with success.

WM. R. PRINCE,
Linnæan Nurseries.

Flushing, New York, May 16, 1868.

NOTE BY ED. C. F.—We publish the foregoing communication, without, of course, endorsing it, having had no experience of the yam in this country, though many years ago our lot was cast where it was a principal article of diet. Our American exchanges speak favorably of it; and experience only can determine its value as a Canadian farm crop. There could be no harm in a cautious experiment next season, the time having passed for trying it during the present year. No Canadian will agree with our correspondent's assertion, that potato-growing has proved a failure in the north.

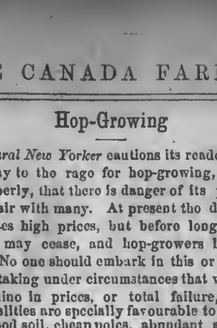
THE YELLOW ABERDEEN TURNIP has been found one of the most profitable varieties for field cultivation, being more solid and substantial, and containing more nutriment than most of the flat turnip family. W. A. Underhill, of Croton Point, N. Y., who has had much experience and success with root crops generally, has raised his own seed of the Aberdeen for the past fifteen years, continually selecting the best and most compact specimens for this purpose. He informs us that during this period he has improved the variety so much, that they weigh five pounds more to the bushel than at the commencement of his experiments.—*Country Gentleman.*

Hop-Growing

THE *Rural New Yorker* cautions its readers against giving way to the rage for hop-growing, and says, very properly, that there is danger of its proving a losing affair with many. At present the demand for hops causes high prices, but before long this state of things may cease, and hop-growers burn their fingers. No one should embark in this or any similar undertaking under circumstances that would render a decline in prices, or total failure, ruinous. Some localities are specially favourable to this business. Good soil, cheap poles, abundant and cheap help, exemption from insects, and proximity to market, form a combination of most advantageous circumstances in certain cases. Still, prudence is wise and commendable. Especially is it of importance that no one should be in such hot haste to go into this business as to attempt to make a hop garden unless the land is in a good, rich, clean, mellow state. We know of some who are attempting to transform poverty-stricken sod ground into a hop-yard. They will find it up-hill work, and accomplish but little for their pains. Land of the very best description, with a deep tilth, and free from weeds, is necessary to success in hop-raising, and it is far better to spend one season in thoroughly preparing the ground, than to plant under circumstances that forbid the hope of satisfactory results. In such cases the maxim is of pertinent application, "make haste slowly."

A Handy and Powerful Lever.

IN working in soft ground, whether at pulling stumps or moving stones, the great want is a firm place to set the lever. We exhibit in the accompanying engraving a lever, which requires a very simple base, and if rigged with a pulley or "block and tackle," as shown, may exert a great lifting power. For such lifts a crooked lever has many advantages. We witnessed, a short time since, the operation of such an one, and were struck with its utility. The ring to which the powerful inch-iron



hook is attached should perhaps pass through the bar closer to the inner angle than is represented. It might equally well be made so as to slip over the bar and hold in a notch on the inner side. Such a lever may be seven to nine feet long, and made of oak or hickory. It may be operated by hand, by attaching the upper end of the rope to a stump and pulling down upon the lower end; or by horses or cattle, by fixing the lower end and carrying the upper one off to where the team may be conveniently and efficiently used.—*American Agriculturist.*

LIMING HAY.—Liming hay that is put into barns in a partially cured state has been recommended by numerous agricultural writers within the past three years. A contributor of the *Prairie Farmer*, Chicago, gives corroborative testimony in favor of air-slacked lime for preserving clover hay which had been imperfectly cured. He says he applied a peck of lime to the ton—sprinkling each layer as it was put into the mow. The result was, it came out bright and green—all stock eating it greedily, and thriving well upon it. Clover and some other grasses lose much of their nutritive properties by being cured overmuch, or if left in the field too long, exposed to sun, rain, and dew.

Haymaking.

GRASS and clover, when ready to be cut down, contain a considerable quantity of sugar, gum, mucilage, albuminous and other soluble compounds, which are all liable to be washed away by heavy showers of rain. As long as grass is still quite fresh, rain falling upon it has little or no injurious effect, for fortunately a coating of waxy or fatty matter covers the epidermis, and wraps, so to speak, the whole vegetable matter in a waterproof mantle. Rain, for this reason, may fall for days on newly cut grass without doing any injury to it; but the case is very different if, by repeated turnings, the crop has become more or less bruised and rain then descends upon the half-made hay; not only are sugar, gum and other soluble matters then liable to be washed out, but the bruised state of the plants, admitting at least a partial diffusion of the various constituents through the lacerated cell-walls, induces fermentation, which, if not checked at once, causes further loss. During the fermentation soluble albumen and sugar are destroyed—two of the most valuable elements of nutrition. In showery weather, grass recently cut should, for this reason, not be turned over more than is absolutely necessary, and under all circumstances it is desirable to handle the crop as lightly as possible, in order that it may not get much bruised.

I have seen farmers spending labour in turning hay on overcast days, on which a dew-point hygrometer showed the air to be nearly saturated with moisture, proving that evaporation could not possibly take place at the time, and rain might be expected at any moment.

As long as grass and clover are still quite fresh, the proportions of water to sugar in the green plant are too large to encourage fermentation; the nitrogenous constituents in newly-cut grass, moreover, only become ferments after the vitality of the plant has been destroyed, and the vegetable cells and vessels have become ruptured by partial drying, and their contents have been mingled together. With the evaporation of water, and the more or less complete destruction of the living organization of the plant, the conditions become more favourable for active fermentation. Should the weather unfortunately turn showery at that stage of the haymaking process, and the air become saturated for many days and weeks together, the half-made hay often begins to ferment already in the field. When this takes place, the hay loses in quality, and becomes much more liable to heat afterwards in the stack. If, on the contrary, fine and warm weather sets in, and evaporation sets in with rapidity, the percentage of moisture soon sinks sufficiently low to prevent altogether, or greatly to retard, fermentation. The hay remains sweet and shows far less tendency to heat in the stack, even if it actually contains more moisture than hay made in unfavourable weather. The more quickly the hay can be made in the field, and the less it gets bruised, or loses colour there, the less likely it is to heat in the stack. Much hay is injured, however, when it is quickly made and in a fine season; it looks to be ready before it is so.

If dried ever so much and ever so carefully in the field, hay nevertheless heats to some extent in the stack. A slight fermentation, so far from being injurious, may be useful, for, as is well known, peculiar aromatic principles are thus generated, which certainly renders hay more palatable, and, it may be, more nutritious. As long as the green colour is retained, there is no danger of the hay losing in quality, but if the heat in the stack becomes so intense and continuous as to turn the hay decidedly brown, I have no hesitation in saying that considerable loss in feeding matter is incurred.—*Dr. Voelcker in Journal of Royal Agricultural Society of England.*

Ditching Machine.

A DITCHING machine has recently been brought out and patented in the United States by an American inventor, which is well spoken of by parties who have seen it in operation. It is known by the name of the Sawyer and Barber Ditching Machine, and is manufactured by A. D. Ricket, Arlington, Ohio. It can be worked, we understand, with one horse, and is said to be adapted for almost any ordinary soil. Farmers in Northern Ohio, we are told, are using them extensively. In that section of country it is customary for the owners of this machine to execute ditching at the rate of ten cents a rod. The machines are made of different sizes, the smaller, to cut from one to three and a-half feet in depth, and the larger to cut from one to four feet deep, and eight or nine inches wide. There are many places in this country where such a machine is much needed.

Transmutation of Species.

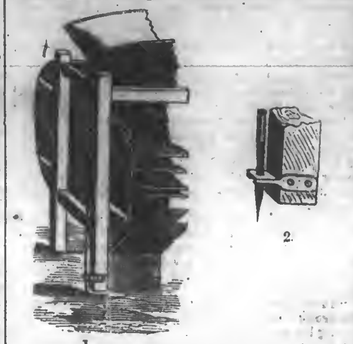
WE were surprised to find in the columns of a contemporary daily paper recently a statement, on the authority of Elihu Burritt, that in a field near St. Ives, in England, a crop of barley was produced from oat seed. The thing, it is needless to say, is simply impossible. We are all familiar with the changes that result from hybridization. These are numerous and remarkable, but have, nevertheless, their limit, and never, under any circumstances, effect the transformation of one species into another. No amount of crossing would produce a horse out of an ass; and just as absurd would it be to expect by any process to transmute oats into barley, or any other distinctly marked species among the cereals. The subject brings up the long-vexed question of the conversion of wheat into chess, of the probability of which, notwithstanding the strongest evidence to the contrary, some not very close observers are still confident; and one of this class has even ventured to back his opinion by a wager to the amount of $1000, that he will grow wheat from chess. On this subject we quote the following very just remarks from the *American Agriculturist:*

WHEAT—CHESS—A $1,000 OFFER.—Some still complain because we do not open our columns to a wider discussion of this subject. We have been looking into the matter for more than twenty years past—have studied it in its scientific relations—have received and read thousands of pages of manuscript, pro and con—have offered prizes, and had men come hundreds of miles with specimens to claim the prizes, and seen them return perfectly satisfied that they had made a mistake. We doubt not that many are honest in their belief that wheat will really produce chess; but we are just as sure that it will not—can not; and while seeking to devote our columns to such topics as will most benefit the largest number of our readers, it does not seem profitable to take up further space on this particular subject. Please allow us the same liberty of judgment in this respect, that we cheerfully accord to others.—We will only add here, that Mr. L. Gore, Chagrin Falls P.O., Ohio, an old and successful farmer, is fully convinced that wheat will turn into chess, and to show his faith, and, if possible, settle the question, he offers to wager $1,000 that he can produce chess from wheat or rye, or both. His neigebour, Mr. David Robinson, will make affidavit that he has taken a kernel of chess from a wheat stalk, where it certainly grew. Mr. Gore's directions for securing the change are as follows: 1st. Sow rye in spring, and pasture it all summer; the next spring it will yield chess. 2nd. Sow winter wheat, or rye, or both in June, pasture until December, and let it grow the next season.—If any are disposed to try the question with Mr. Gore, they can correspond with him—we give his full address above. We have not time to take part in the correspondence, but we advise Mr. G. to look out for his $1,000, if an enterprising man should accept his proposition. Perhaps he could not better use the money for the good of mankind, than to lose it in "settling" this "vexed question." Please excuse us, if we do not publish or answer the next hundred letters that come in about Wheat *vs.* Chess.

GROWING WATERMELONS.—At a recent meeting of the Herkimer County Farmers' Club, Judge Owen stated that he had a piece of land ploughed a foot deep, turning up the clay subsoil, which he planted with watermelons. The plants came up; but the sun dried and hardened the clay, and the vines did not thrive. He then went to the dung heap, and took from the centre a wheelbarrow load of manure that had thoroughly decomposed into a black mass. This was thrown into a barrel filled up with water. Commenced watering the plants with this liquid, and directly they began to grow vigorously. Thinned out the plants to two in a hill, and continued the application of the liquid, filling up the barrel with a fresh lot of manure and water from time to time. When the plants got fairly under way, they would make a growth of ten inches in twenty-four hours. Finally thinned out, leaving only two plants, and they in time covered all the ground. These made an enormous yield. One of the melons weighed twenty-eight and a-half pounds: six others weighed one hundred and twenty pounds. From this patch he picked all the melons he wanted for family use, and for the entertainment of his friends, and to close up in the fall he took off half-a-dozen wagon-loads of unripe melons. This satisfied him that the best way to apply manure to vegetables is in a liquid state.

Fixed Foothold for a Fan-Mill.

BARN floors are somewhat uneven, and fan-mills have not weight enough to stand steadily when turned with a strong arm, to give a forcible blast, so they slide and dance about unless fastened by cleats or otherwise. Mr. Ellwood Hughes, of Fowlersville, Penn., sends the *American Agriculturist* the following description of an attachment to his fan-mill, which he finds of great service: "A bar of round ¾ iron, long enough to turn a short handle above the top of the leg of the fan-mill, has a thread cut at the bottom and passes through a nut fastened at the bottom



1.

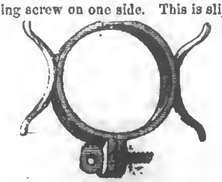
2.

of the leg. The end of the rod is sharpened to a point so as to take hold in the floor, and the top passes through a staple in the top of the leg. Such a rod should be attached to two of the legs of a fan-mill, so that they may be screwed down to take hold in the floor. Thus the mill will retain its place while in use, and stand level, no matter how uneven the floor. When one has done using the mill the rods may be run up, and then the mill will slide smoothly over the floor." Figure 1 shows a portion of the fan-mill with the rod attached, and fig. 2 gives the screw at the lower end of the rod with the nut.

WHETSTONE HOLDER AND GUARD.—In using a stone for sharpening a scythe, beginners or inexperienced persons often cut their hands against the edge. Then, again, the best stones are usually fragile and likely to be broken into pieces too short to hold in the hand. We bought in London a little instrument use-

1.

ful in both of the above cases. Fig. 2 is a little ring of zinc-coated iron, with four flanges or prongs and a tightening screw on one side. This is slipped over



2.

a wooden handle cut out in the centre like a clothespin, (fig. 1). A whole stone, or a broken half of one, is securely fastened by turning the screw, which enables one to use up fragments, or to use very short stones; while the flanges guard the hand from being cut, if a wrong movement happens to be made.—*American Agriculturist.*

Plaster as a Manure.

GYPSUM, or plaster of Paris, is a sulphate of lime, in other words, a combination of lime and sulphuric acid in certain proportions. It is found in certain localities in the form of a hard, white, semi-opaque rock, which is dug out or blasted, placed in kilns, and subjected to a strong heat, which drives out the water, &c., and renders it brittle; it is then ground fine in mills erected for the purpose. When first ground it is very dry, but by exposure to the atmosphere gradually imbibes water, which adds greatly to its weight. It can hardly be called a manure of itself, for it only acts as an absorbent of ammonia and other salts that exist in the moisture of the atmosphere. Its good effects are most manifest when applied as a top dressing to clover, peas, and other leguminous crops, at the commencement of dry weather, when, from its absorbent power, it draws and retains the moisture from the night dews, (which contain much ammonia,) to the roots of the young growing plants. It also greatly benefits corn, potatoes, and other hoed crops, when applied sparingly to the surface of the soil, close to the young plants, when they are two or three inches high. 100 lbs. per acre is about as much as will be necessary to sow on clover, but more may be sown with advantage where the soil is deficient in lime. The lighter and drier the plaster is the better, and it should be kept in tight barrels in a dry place till wanted for use, as if once it gets wet its value is destroyed.—*Ex.*

The European Larch.

THIS is well known as a beautiful ornamental tree, and as such is to be found in most gardens that have any shrubbery about them. From its quick growth, the *Country Gentleman* recommends its culture for timber, and estimates that in twelve years the larch crop on an acre of ground would be worth twelve hundred dollars, thus giving a yield of one hundred dollars per annum to the acre. Our cotemporary also advises the use of this tree as a screen, since though it is deciduous, it affords a much better protection than other trees which drop their leaves, on account of the profusion of small shoots which break the force of cold winds. The larch is easily grown from seed, which should be sown half an inch deep in beds of fine, rich mould, and shaded from the sun the first season.

WHAT OUR FARMERS REJECT.—The Ogdensburgh *Journal* says:—The canal boat *Solon F. Case* is at Anvil's dock in that city, taking in a cargo of leached ashes, which have been purchased from the asheries there. These are taken to Long Island and Connecticut, and sell at from eighteen to twenty-five cents per bushel as a fertilizer. Yet, says the Mitchell *Advocate*, here, where our farmers can get them for nothing, they are rejected as worthless. Science and experience, however, teach otherwise, and we find those who possess the knowledge coming nearly a thousand miles to procure what our farmers reject."

WORMS IN CORN.—If your cornfield is troubled with worms, scatter salt around the hills in small doses of a handful to a half-dozen hills, or at the rate of five or six bushels to the acre. Mr. Greeley has tried it; and finds that nine-tenths of the worms in the ground are killed by it, particularly the wire-worm.

SHOULD POSTS BE PLANTED UPSIDE DOWN.—A correspondent of the Farmers' Club, American Institute, says he has tried both ways—that in which the tree grew, and reversely—and in ten years' trial has found no practical difference.

HOPS.—People entering into the hop business had better count the cost before commencing, lest they hop out faster than they hopped in.—*Cor. Country Gentleman.*

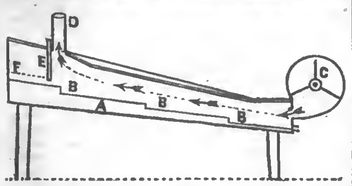
Bones and Ashes.

BONES and ashes pass through the housekeeper's hands every day. Wood is still the chief fuel in the farm-house and the value of the ashes is pretty well understood. They are prized for the lye they yield, and if there is a surplus from the soap-making they help the kitchen garden at the back door. The bones are generally thrown to the dog and lost. Now if the careful housewife would save the bones as regularly as the ashes, she would practise a wiser economy and help her kitchen garden twice as fast. Bones are worth twice as much as ashes for manure, if dissolved, and the ashes will reduce them. Put both into a barrel in the cellar, if you please, and after mixing them half and half, keep them constantly moist with soapsuds, the hotter the better. The ends should not be poured on in such quantities as to leach the ashes. In a few months the bones will be disintegrated, and the whole mass may then be mixed and will make an excellent fertilizer for the flower border or the kitchen garden.—*American Agriculturist.*

The Dairy.

Milk Cooler.

AMONG the contrivances the need of which has been seriously felt by cheese-makers on the factory system, is an efficient method of rapidly reducing the temperature of new milk, and depriving it of some portion of its animal odour. In the States various contrivances for the purpose have been patented, the principle of which is to pass the milk in tubes arranged in coils, through cold or iced water. This plan will, no doubt, lower the temperature, but seems to us deficient in the important point of removing at the same time the odour of the milk. An invention has recently been patented in this country which seems to combine both the desirable points. This contrivance was invented by Mr. F. Oakley, of Bond Street, Toronto, and is represented in the accompanying illustration. The apparatus is very simple, and will be at once understood by a reference to the drawing, in which the principle of the operation and the various parts of the mechanism may be clearly seen. These last consist of a covered trough (A), with a series of steps (B) (B) on an inclined plane, a fan blower (C), worked by hand or any available power, a chimney or air duct (D), to carry off the warm and impure air, as shown by the arrows, a movable sluice or floodgate (E), to regulate the flow of the milk, a strainer (F) to remove hairs, &c., that might be in the milk.



To this might be added, around the compartment which receives the milk, receptacles for ice, which would still further aid the cooling effect. This improvement is, we believe, contemplated by the inventor. The principle might also be advantageously applied to other processes besides cheese-making.

Rearing Calves.

THE following is an extract from an essay on "Dairy Stock and its Management," read by Mr. Phineas Stedman, of Chicopee, before the Franklin (Mass.) Farmers' Club:

We come now to our second topic, viz.: "The management of dairy stock." It is of the first importance that all farm stock be kept in a thrifty, growing condition. It is much easier to keep a young animal growing, than it is to start that animal after it has, by want of care or proper food, been allowed to stop growing. Could every farmer be properly impressed with the fact that when a young animal is fed only sufficient to maintain its present condition and weight, that amount of food is lost, an important point would be gained. I know of no single item in which we suffer so much loss.

The best method of rearing dairy stock will vary with different individuals. To rear calves dropped in spring, a good, and I think economical method, is to put two calves to a cow, (provided one not too valuable is at hand,) and turn to pasture. I prefer, however, to have them dropped in autumn, or between October and January. They may be allowed to take the milk from the cow at regular intervals, or be taught to drink the milk, and at three or four weeks old, skimmed milk may be substituted, and the calves will thrive well, with the addition of good hay and provender. For provender, I know of nothing better than a mixture of unground oats and linseed meal, in equal parts. At three months old, an ordinary calf will take two quarts of this feed and a small quantity of roots, without injury. Calves dropped at this season, have several advantages over those dropped in spring. They usually receive better and more regular care, are better prepared to endure the cold of the succeeding winter, and until they arrive at maturity, always hold an advance of several months, in age and size, while reckoned in the same class.

Over-Production of Cheese in the States

CANADIAN farmers and dairymen may derive many useful lessons from the experience of their American neighbours, who are older in the business than those on this side the border; and though we do not think there is any just cause for discouragement in the present prospects of Canadian cheese-making, yet it is as well to take timely warning, and avoid the evil of multiplying factories too closely together; and especially is it necessary to bear in mind that nothing short of the highest excellence in the article manufactured will ultimately render cheese-making profitable. The following remarks, by X. A. Willard, Esq., on the production of cheese in the United Sates, deserves the thoughtful attention of Canadian manufacturers:—

"The prospect of American cheese dairying cannot be regarded so remunerative a business in the future as in the past.

"The opinion has gone abroad that there is no branch of farming so profitable as the dairy. The consequence is that many are changing their system of farming, and rushing into cheese-making, when really better results would be secured by keeping steadily along in the business with which they are familiar.

"Dairying is now so extended that it will need the best united efforts of producers to make the business pay. Every increase is fraught with danger, and it is important that correct and reliable information be disseminated in regard to the extent and profits of the business.

"In the first place it may be well to inquire what the production is, and what the increase has been during the past eight years.

"According to the census of 1860, the production of cheese in the New England and the Middle and Eastern States was 101,000,000 pounds. New York then made 48,548,289 pounds; the Eastern States 21,620,986, and Ohio 21,618,893 pounds. According to the last New York State census, the cheese sold from the factories and dairies of New York alone, in 1864, amounted to 72,195,337 pounds. We know there has been a large increase of dairies in the State during the past four years, and from the best information I can get, New York is producing, in an average good year, at least 100,000,000 pounds.

"The increase in the Eastern States has been large and probably will not fall short of 40,000,000, while the Western and Middle States, New York excepted, must be at least 50,000,000. We have, then, 200,000,000 pounds of cheese as the product of the States, exclusive of the Southern and Pacific States and Territories. If to this we add 15,000,000 for Canada, we have the immense annual product of 215,000,000 pounds.

"We are exporting to Great Britain from 50,000,000 to 60,000,000, which leaves 160,000,000 pounds to be worked off among our own people.

"It must be evident that we cannot go on increasing this business without over-production, and those about entering upon it may well hesitate before making investments.

"As to the large profits from dairying, if the past year is to be a sample, it will require a magnifying glass of more than ordinary power to see them. Many have barely made the ends meet, and some have not been able to pay expenses."

Salting Butter, &c.

As to the quantity of salt to be used for butter, something will depend upon its manufacture and the market for which it is intended. The Orange county butter makers, who obtain the largest prices for their product, use at the rate of a pound and two ounces of salt for a batch of twenty-two pounds of butter. For winter butter, or butter designed for winter use, a little more salt is used at the last working.

There is a difference of opinion among butter makers in regard to washing out the buttermilk. We are strongly impressed that butter will keep best that is properly washed. It is the caseous or cheese particles in the buttermilk, the decomposition of which causes the butter to become frowsy or rancid. The more perfectly these are expelled the better will the butter be preserved sweet and sound. Washing properly, to our mind, secures best that result. It is certainly much less work to get rid of the buttermilk by washing, than by the "kneading process," besides there is less danger of spoiling the butter by overworking, since overworking injures the grain, rendering the butter salvy. It is claimed by some that when the buttermilk is worked without washing a more delicate aroma is retained, and this principle is observed in Holstein and Normandy, where a very superior butter is manufactured for the London market.

We have tested hundreds of samples of butter in London which came from France and Holstein. The butter is very slightly salted, and when fresh, has a most delicious flavor, but much of it does not keep well.

A most important point to be observed by buttermakers who hope to make a reputation for fine goods, is to pack in suitable tubs or packages. In our opinion, there is no wood so suitable for butter packages as white oak. The timber should be well seasoned, and the packages strongly hooped, so as to be water-tight. No leaky package can preserve butter for any considerable length of time.

In salting cheese, much will depend upon manufacture and the time it is desired to have it ready for the market. From two and a-half to three pounds of salt are usual for one hundred pounds of curd. The usual quantity at the factories is 2.7-10 pounds salt to 1,000 pounds of milk. In spring, when it is an object to have the cheese go into market early, 2½ pounds salt, and even less, are used to the 1,000 pounds of milk.—X. A. WILLARD, in *Utica Herald*.

DAIRY MEETING AT STOUFFVILLE.—The Markham *Economist* says the dairy meeting at Stouffville, held on the 3rd inst., passed off very agreeably. The result is that the Stouffville Factory was to go into operation on Wednesday, 10th inst., with the promise of about 100 cows to start with, and a prospect of considerable increase.

☞ In France, milk is packed in small tin cans, easily moved by one man, and by a simple contrivance the stopper screws close down upon the contents of each can, so that the motion of the railway cannot churn the milk *in transitu*. The cans are then placed in covered waggons, and in summer are wrapped in cloths, which are watered from time to time so as to promote coolness by evaporation. The result of this care, which costs but little, is that the milk supply of Paris is proverbially excellent.

MILKING MACHINES.—A correspondent of the N. H. *Mirror* and *Farmer* gives his experience with one of these machines. He saw them advertised, and bought one, paying $7 for it and $5 for the right to use it. He says: "I tried it on an easy milker, and after a good deal of effort succeeded in getting it adjusted on the cow's teats, and by working it could draw some milk, but by the time the cow was half milked the teats would not fill the cups, and the machine would drop off, there being no suction. I wrote to the agent, stating the difficulty, and asking to be referred to some one who had one in successful operation. The agent replied, giving no reference, probably for the all-sufficient reason that there was nobody to refer to, but saying that I must persevere, for it required a good deal of practice to learn to use one. I and my hired man tried until we supposed that we had exhausted all our mechanical talent, but without success, and laid the machine by, which the agent can have at a very large discount."

NEW CHEESE HOOP.—At a late meeting of the Herkimer County Farmers' Club, Mr. E. Ellis exhibited a new cheese hoop which had been recently invented and patented. Mr. Ellis said there was great complaint among dairymen in regard to removing the cheese from ordinary hoops, and Mr. Purdy, who had been with him for some time manufacturing the common wooden hoops, had turned his attention to the subject in order to obviate the difficulty. As a result, he had brought out a new hoop, which had been patented, and he thought it an improvement. The hoop shown was of galvanized iron, arranged with an ingeniously constructed clasp, so as to be in a moment unlocked, when the hoop opens and the cheese can be taken out. This seems to be a very desirable article. It is very simple in its arrangement, being readily locked or unlocked in a moment.

Stock Department.

The Circulation of the Blood.

UNDER this head the course of the circulation was described in the last issue. It is now proposed to resume and complete the brief notice of the subject in the present article. The division of the heart into four chambers, the purpose of the arrangement, the contractions of this muscular organ, and the valvular apparatus by which the blood is propelled in one particular course, have been already explained: two phenomena, however, connected with the heart's action remain to be noticed, viz., the impulse or beating of the heart, and the sounds that attend or immediately follow the action. The first of these is familiar to every one, is sometimes visible to the eye, and can be readily felt by the hand, applied to the left side, particularly over the fifth and sixth ribs, where a slight but distinct stroke is felt against the walls of the chest. This beat or impulse is caused principally by the contraction of the spiral fibres of the ventricles, a movement which, at the same time that it shortens the heart, tilts up its point, and causes it to strike against the side. This contraction of the ventricles gives rise to a dull sound, which can be detected by the ear applied to the chest; and this first sound is almost immediately followed by another, somewhat sharper and quicker, which is due to the sudden closing of the semilunar valves of the arteries described in the last article. These sounds become modified and altered in disease of the heart, and afford important aid in detecting the existence and discriminating the nature of the morbid conditions of that organ.

From the heart the blood is poured into tubes called blood-vessels, which as they spread repeatedly divide into branches, till at their extreme ramifications they form a very fine net-work of minute tubes, so small that some of them will only permit one blood corpuscle to pass at a time, and so close together that the point of a needle cannot be inserted without puncturing one of these vessels and allowing the blood to escape. It requires a microscope to render these ultimate divisions of the blood-vessels and their contents visible to the eye. It is worthy of note that, whenever an artery or vein divides into two branches, each of these branches is smaller than the tube from which they bifurcated, but their joint capacity is greater. Hence it follows that the total capacity of the extreme and minutest vessels, called the capillaries, is considerably greater than that of the main trunks. As the result of this increased area, the motion of the blood in the last named vessels is slower than in the larger trunks; just as the current of a river becomes slower as its channel widens. This is, no doubt, a provision for the due performance of those vital functions in which the blood is the prime agent, and which take place during its slackened course through the capillaries.

There are certain very marked peculiarities in the vessels which first receive the blood from the heart, and which are called arteries. Like that of all the blood-vessels, their internal coat, or lining membrane, is very fine and smooth, so as to oppose the least possible friction to the passage of the blood through them; but they differ materially from the veins in having their principal coat composed of a very elastic tissue; so that when distended by the influx of blood, which increases momently both their diameter and length, they naturally recoil and recover their ordinary dimensions. Each gush of blood into the arteries thus distending and lengthening them by a motion propagated throughout their length in a sort of wave, tends to make them bulge out and straighten their curves. This action produces the *pulse*, of which we shall speak presently. But first let us notice an immediate and important effect of this distension and recoil; which is, that the shock of each fresh gush of blood is gradually overcome, and by the time the stream reaches the capillaries, the motion is no longer in jerks, but perfectly continuous and smooth, and passes in the same even current into the veins, which return the blood to the heart. That the flow of this important fluid should thus become not only slower, as we have seen, but quiet and smooth in those delicate and minute tubes where the vital functions are carried on, is no doubt the principal object of this simple, yet beautiful mechanism. There is a consequence rather than design of the elasticity of the arterial coat that should be noticed in this place; namely, that if one of these vessels be punctured or cut, the opening dilates and presents a gaping and somewhat circular aperture, with no disposition to collapse, as in the more flaccid walls of the veins. Hence a wound of an artery produces a much more dangerous escape of blood, and much more difficult to check, than a wound of a vein. Indeed, the only effectual means of arresting hæmorrhage in arteries of any considerable size is to tie the vessel.

Let us now return to consider briefly the *pulse*. This beat, which in certain situations is perceptible to the eye or the touch, is caused by the momentary distension and straightening of an artery in consequence of a fresh wave of blood, propelled into it from the heart. Hence the pulse affords a most important index of the heart's action, showing the frequency, strength, and other characteristics of its central pulsations. The pulse of the remote arteries is not exactly simultaneous with the beat of the heart, but follows very quickly after; that at the wrist in man being about the seventh of a second behind the contraction of the heart. The contractions of this organ, producing corresponding changes in the pulse, are increased in rapidity and force by a variety of circumstances, such as violent exercise, mental emotion or excitement, and by a condition of fever or inflammation. It is, therefore, useful for any one to know what should be the regular and healthy frequency of the pulse. Its rapidity is greater in young animals than in the old, and varies considerably in different animals. Taking the adult average, the healthy pulse is in man about 70 in a minute; in the horse from about 34 to 44; in the ass a little faster; in the ox from 35 to 42; in the sheep, 70 to 80; about the same in the goat; and in the dog from 90 to 100 in a minute. The situations where the pulse can most conveniently be felt vary somewhat in different animals. In man it is frequently visible on the temples of thin or aged persons, and can readily be felt at the wrist. In the horse it can be felt on the inner and under side of the lower jaw, just in front of a conspicuous tuberosity or prominence on its suface. In the ox the situation for examining it is nearly the same, but a little more forward. In sheep the carotid arteries of the neck, or the metacarpal arteries of the fore-leg, or those at the root of the tail, afford the most perceptible pulsations; and in the dog the pulse may be felt at the fore part of the root of the ear. In judging, then, whether inflammation or fever be present in any case, it is important to remember that the pulse is much quicker in young animals than in the adult; in colts, for instance, than in older horses. We must also bear in mind that it is temporarily quickened by fear or any nervous excitement. This is particularly the case in the horse, an animal of highly excitable, nervous temperament. It is necessary, therefore, in making our examination, to be very quiet and gentle in our proceedings; and it is well to repeat the investigation, at intervals, to ascertain whether the acceleration, when present, is persistent, or merely the result of temporary excitement.

We must now pass on to notice very briefly the remaining vessels concerned in the circulation, namely, the capillaries and the veins. The capillaries form the ultimate ramifications of the circulatory system. They are distributed in a fine net-work over every vascular part of the body. By the aid of a good microscope these minute vessels and the course of the blood through them can be beautifully seen in some transparent living structures. The web of a frog's foot, and the tail of the salamander, an animal common in pools of water at this season of the year, afford excellent illustrations. These vessels have very delicate walls or coats, which are easily ruptured, but have no pores or openings. Their membranous walls are, however, perfectly pervious to air or gases, as we shall notice in another place, when we come to consider the function of breathing.

From the capillaries the blood, propelled by the action of the heart, flows into the veins, the branches of which gradually unite into larger trunks till the great vein of the system is reached, which pours the blood into the heart. The only peculiarity of the veins that we shall here mention, is that of the valves, with which the larger vessels especially are numerously furnished, and which resemble in structure the semilunar valves of the main arteries, consisting, however, of only two pouches in one place, instead of three. Their office is to prevent the return of the blood in a backward direction when they are pressed upon by the contraction of the muscles along which they pass. It was the examination of the valvular apparatus of the heart, arteries, and veins, all tending to admit the passage of fluid in one direction only, that led Dr. William Harvey to the discovery of the circulation, and entirely exploded the old notion that the arteries, as their name would indicate, contained air. We now know that the admission of air into the blood-vessels is instantly fatal. This accident sometimes happens in wounds of the chest, or root of the neck, or those situations where the veins are bound to bony or other rigid structures by fascia. It is an accident of extremely rare occurrence, as the continuous stream of blood occupies the tubes to their full capacity. The effect of introducing air into blood-vessels is, however, sometimes used as a merciful means of instantaneously and painlessly putting an end to life. When a horse, for instance, has become superannuated, or hopelessly injured, and it becomes an act of necessity or mercy to kill the animal, this may be quickly done without inflicting pain by blowing air into a vein, say of the neck, through a quill.

To prevent or arrest a dangerous escape of blood from the vessels, nature has made many effective provisions, among which we can only mention the chief. Thus, the larger vessels, especially the arteries, are usually deeply seated, and lie in a course where they are well protected by adjacent parts; while the flow of blood from the smaller veins and capillaries, unless very extensive or under peculiar conditions of disease, is seldom dangerous. The natural mode of stopping hæmorrhage is this: the blood, when it has escaped from any vessel, and especially if it comes into contact with the air, tends very quickly to congeal and form a clot, which acts as a plug, and puts a stop to any further bleeding. As a practical lesson, we should learn from this not to be too officious in washing away the flowing blood from a wound and thus preventing the coagulation which would naturally take place. Lint or other similar materials, such as the pile of a hat, cobwebs, &c., entangle the blood and facilitate its coagulation. Pressure properly applied brings together the walls of the wounded vessel, or closes the opening. But in applying it, we should bear in mind the course of the circulation (*from* the heart in the arteries, *towards* the heart in the veins), and apply it behind the wound of a vein, that is, more distant from the heart, rather than in front of it, which in the case of a vein would only increase the escape of blood. When a surgeon opens a vein in the arm for the purpose of bleeding, he applies a ligature above the wound; when he wishes to stop this flow of blood he applies the ligature below it. When any considerable artery is wounded, no time should be lost in sending for a surgeon. A pulsating stream of bright red blood flowing in jets is a sure indication of a wounded artery. The first thing to be done in such a case is to press firmly with the finger or thumb over the artery, especially, if it can be done, against a bone, remembering in this case also the course of the circulation, and applying the pressure accordingly. In the case of a wounded artery in a limb, a temporary tourniquet can be applied by a handkerchief surrounding the limb, twisted into a knot over the wound, or between it and the heart; or some hard substance, such as a piece of cork, or even a stone, may be placed in this situation under the bandage, which should be tightened and firmly held by a piece of stick, twisting the ligature thereby as much as may be necessary. A little coolness and presence of mind in these emergencies may often save life.

Experiment in Feeding Leicester and Merino Sheep

A RECENT number of the *Country Gentleman* gives an interesting account of an experiment made by Mr. Jurian Winne, in the neighborhood of Albany, N.Y., to ascertain for his own satisfaction whether the claim on behalf of the Merinos that if they weigh less than English sheep they also consume less food, and are equally profitable to fat for the market, is well-founded or a mistake. The whole number of sheep fattened by this gentleman the past winter was 901, of which 180 were Merinos. The aggregate amount realized for the whole has been $12,049.15 *net*, that is, above all freight and expenses in New York—an average of $13.37 per head, which, on so large a number, is extraordinarily good. By way of experiment, two lots were set apart, consisting respectively of 60 Canada Leicesters and 61 Merinos; they were weighed Feb. 10th; a careful account was kept of all the food they consumed during the continuance of the experiment, 46 days, to March 28, when they were again weighed and sent to market. These numbers were thought to represent fairly the whole, and were taken as avoiding the trouble and additional risk of error, which would have been incurred by large numbers. The experiment began after both lots had been got in good progress—the previous and subsequent treatment of both having been precisely alike. The Merinos were an extra good lot, the 180 having been selected out of 600—and no complaint could exist against them, as we know by personal examination, on the ground of being below the best merits of their kind.

The following are the figures as regards weight, &c.:

Feb. 10—60 Coarse Wools weighed	6,870 lbs.
March 28— do do	9,878 lbs.
Gain in 46 days	1,008 lbs.
Total cost of feed (hay, grain, oil-meal, roots, &c.) for the 46 days,	$174.43
Feb. 10.—61 Fine Wools weighed	6,909 lbs.
March 28— do do	7,389 lbs.
Gain in 46 days	480 lbs.
Total cost of feed as above	$144.78

When both lots were sold, March 31st, the former realized 10¾ cents per lb., and the latter 10½ cents. A calculation in simple proportion will show that if the coarse wools gained 1008 lbs. at a cost of $174.43 for feed, the gain of the fine wools at the same ratio upon an exposure of $144.78 should have been 836 lbs., whereas it was only 480 lbs., or a little more than one-half a proportionate amount as compared with cost. As compared with live weight, Feb. 10th, the coarse wools gained 11½ per cent. in the forty-six days—the fine wools not quite 7 per cent.

How to Fit Collars to Horses' Shoulders.

It is very important to have a collar fit nicely and snugly to the shoulders of the horse. It enables him to work with a great deal more ease and to apply a great deal more strength. It prevents galling and wounding, as the friction is avoided. Collars are so made, or should be so made, as to throw the chief force on the lower part of the shoulder. The horse can apply but little strength on the upper part, and for this reason breast collars are coming greatly into vogue—as the strength is exerted on the lower part of the shoulder. But we started out to tell our readers how to make a new collar fit the shoulder of the horse. The collar should be purchased of the proper size; just before putting it on, the first time, immerse it in water, letting it remain about a minute, and immediately put it on the horse, being careful to have the hames so adjusted at top and bottom as to fit the shoulder, and then put the horse to work. The collar, by being wet, will adapt itself to the shoulder, and should dry on the horse. When taken off it should be left in the same shape it occupied on the horse, and ever after you will have a snug fitting collar and no wounds.—*Valley Farmer.*

THE BEST KIND OF HOGS.—A correspondent of the *Prairie Farmer*, after experimenting ten years with nearly every breed, has come to the decided opinion that "the Suffolk will furnish the most pork for the least money, and with the least trouble, over any other kind of hogs." He considers them "the easiest kept, and perfectly harmless; they make the least offal, and are ready at any time for the butcher."

Cattle Soiling in the United States.

A good authority states it as his experience, that "one and a half square rods" will yield an ample supply of green food for each head of cattle for one day. To adjust the cropping for this, "the length of time it will take the article sown to come to maturity, so as to be fit to be cut, and the length of time it will afterwards continue succulent, are to be considered." The following notes by the authority above quoted, will give a few hints as to the system:—

1. As early in April as the state of the land will permit, which is usually between the 5th and the 11th, on properly prepared land, oats, at the rate of four bushels to the acre.

2. About the 20th of the same month, sow either oats or barley at the same rate per acre, in like quantity and proportions.

3. Early in May, sow in like manner, either of the above grains.

4. Between the 10th and 15th of May, sow Indian corn, the flat southern being the best, in drills, three bushels to the acre, in like quantity and proportions.

5. About the 25th of May, sow corn in like quantity and proportions.

6. About the 6th of June, repeat the sowing of corn.

7. After the last mentioned sowing, barley should be sown in the above-mentioned quantity and proportions in succession; on the 15th and 25th of June, on the 1st of, or early in, July, barley being the best qualified to resist the early frosts.

The results of the above sowing, in succulent food, may be expected to be as follows, seasons of extraordinary drought excepted:—

The oats sown early in April will be ready to cut for "soiling" between the 1st and 5th of July, and will usually remain succulent until the 12th or 15th of this month.

Those sown about the 20th of April will be ready to cut between the 15th and 20th of July, and will last nearly or quite till the 1st of August.

Those sown early in May will be ready to succeed the preceding, and last till about the 10th of this month.

The corn sown on the 10th and 25th of May and early in June, will supply in succession succulent food of the best quality until early in September.

The barley sown in July will continue a sufficient supply until early in November, at which time, and often before, the tops of roots, carrots, beets, or turnips are a never-failing resource.—*Ex.*

Stable Floors of Gravel, Stone, and Coal Tar.

AMONG the materials of late recommended for stable floors, are a mixture of coal tar with gravel and stone. The manner in which the work is done is to take small stones and put them in a pile, pouring over the same the gas tar, and then mixing with a shovel until the stones are coated. These stones are now laid upon the floor and raked off level, and a sufficient quantity used to make the floor about three inches deep. Upon this floor coarse gravel, mixed in the same way with tar, is placed. The mixture is effected by putting the gravel in piles and making a hole in the top, pouring in the tar and mixing with a shovel. It is then spread over the stones two inches thick.

No more tar should be used than just sufficient to coat the stones and gravel, as it will be longer in drying. The stones and gravel being laid as above, a heavy roller weighing 400 or 500 pounds is passed over the floor until it is perfectly compact, and any places not touched by the roller are beaten down with a heavy maul. While the rolling and mauling is going on, the surface should be strewn over with fine gravel or sand, to take up the surplus tar, and should be continued until the surface is dry enough to walk upon and not stick to one's shoes. The floor is rat-proof and water-proof, and becomes hard and durable, making, it is said, the best floor that can be put in stables: the only objection being the smell of the tar, which, however, is healthy, and in time passes off. We find the substance of the above in the Vermont *Record*, without any names being given of persons who had tried it. We should presume that a good substantial floor could be laid in this way, and it has the merit of being cheap, and what every farmer and his workmen can readily do, without employing more expensive labour. It looks practical, and is well worth trying.—*Utica Weekly Herald.*

Veterinary Department.

Teeth and Teething in Horses.

To the Editor of THE CANADA FARMER:

SIR,—As the following is a matter of some interest to all who are in the habit of raising horses, and, indeed, to all who are in the habit of keeping horses under five years of age, I have been anxious for some time past to have an answer from the CANADA FARMER to a few queries on the subject.

1st. Should the milk-teeth of a colt rising three, four, or five years old, be taken out as soon as they are loose?

2nd. Are Wolf Teeth injurious to the sight, or will they cause the appearance of heaviness in the eyes?

3rd. Do colts begin to shed their back teeth at the same time they commence shedding their front ones?

4th. Can anything be done for Lampas that would be equal to or better than letting alone? During the last ten years I have owned upwards of a dozen colts which were losing and getting teeth while in my possession, and like my children (when undergoing the latter process especially), their gums have been swollen and sore; but I have never been able to believe that burning the roof of the mouth with a red hot iron and then scratching it with a horse nail would better matters much, either with colts or children.

I have only got what were called Wolf Teeth knocked off the upper jaw of one colt, which at the time was twenty-two months old; and being advised to do so by a person who ought to understand such matters, it did not occur to me then, but it has often occurred to me since, that if colts begin to shed their back teeth at the same time they begin to shed their front ones, it could not have been Wolf Teeth at all that I got knocked off.

An answer to the foregoing queries will be thankfully received by the writer, and ought to be read with interest by many more. J. L.

ANSWERS.—In answer to query No. 1, we consider it advisable to remove the temporary teeth when they become loose and are likely to interfere with the growth of the permanent ones.

No. 2. It is a common opinion held by many people that wolf teeth are injurious to the eyesight; we believe such to be a mistaken opinion altogether.

No. 3. Colts shed the molar teeth from the third to fourth year; the first, second and third in the jaw are temporary, and the first and second are usually displaced by permanent ones about the third year, whilst the third permanent appears about the fourth year. The colt has only twelve temporary molars or back teeth, whilst he has twenty-four permanent, and the first permanent appears when the colt is about one year old, and is the fourth in the jaw. The second appears when the animal is from eighteen to twenty-one months old, and is the fifth. The sixth makes its appearance about the same time that the third temporary one is being shed; so at four years old the colt has a full mouth of back teeth.

No. 4. Occasionally the gum behind the incisor or front teeth are swollen and tender whilst dentition is taking place, and this is known as Lampas. When very much swollen and tender, two or three scarifications with a knife will frequently relieve the inflamed part, but on no account should the hot iron be applied.

What is known as a Wolf Tooth is a small supernumerary tooth in front of the first back tooth. Such a tooth sometimes sets up considerable irritation and interferes with the process of mastication. A wolf tooth is very easily removed.

Do not accustom your horses to the blanket unless you cover them under all circumstances after being driven in cold weather. The blanket is of great benefit if properly used.

Contagious Diseases.

DURING the progress of certain disorders, there are given off from the sick body specific organic particles which possess a wonderful power of self-multiplication, and which, if they come into contact with living animals, are apt to develop the same disease from which they originated. Disorders thus propagated are recognised as catching, contagious, or infectious. They include, amongst horses, glanders, strangles, influenza, and typhoid fever; amongst cattle, pleuro-pneumonia, mouth-and-foot disease, rinderpest, and vaccine pox; amongst dogs, distemper, typhoid fever, and rabies. Although intangible and not usually cognisable by the senses, the specific virus, or *contagium*, as it has been recently termed, possesses a distinct and positive existence. Judging from its behaviour it appears to consist of solid particles, or germs, or cells. That it is not gaseous is evident from the fact that most contagions retain their activity even after passing through the air, or being carried about on the clothes of men, or on other such articles. That it does not consist in a volatile fluid is tolerably apparent from the fact that admixture with water does not always destroy its reproductive power. From the careful philosophical investigations of M. Pasteur it appears now to be tolerably well ascertained that the matter of contagion, whether it came from the ulcerated nostrils of a glandered horse, from the teeth of a mad dog, from the body of a plague-stricken cow, or from any other source, consists of minute spores, germs or cells, which, under favourable circumstances, may preserve their vitality for some considerable time outside the body, may attach themselves to living objects, and may be carried uninjured through the air.

The unsuspected movement of such living organisms throughout the atmosphere is not so difficult to understand when we remember that the small seeds of mushrooms, mosses, and other such plants, are often conveyed in this way for considerable distances. M. Plasteur has, moreover, recently shown that the atmosphere, especially in inhabited localities, is always filled with invisible organisms, which, when they fasten on suitable substances, develop and multiply. In this way mould and other lower forms of vegetation spring up; various putrefactive changes are originated; whilst, what is still more to our present purpose, pus is produced in worms from pus germs settling upon them!

When the contagious virus gains access to the living body, a period of quiescence or incubation occurs, which varies in duration with each virus, and even with the same virus under different circumstances. Mouth-and-foot disease, for example, will sometimes show itself two days after the exposure to the contagion; whilst hydrophobia has appeared in animals several months after they have been bitten by a mad dog. But the living germs are not idle during this period of incubation; they grow and multiply. Like other growing organisms, the germs of any contagion require nourishment, which is doubtless extracted from the blood, or living parts with which the vital cells are in contact. Like other organisms, they probably also contaminate by excretions the body on which they feed. This ingenious view is lucidly set forth by Mr. Crookes, F.R.S., in his excellent Report on Disinfectants presented to Her Majesty's Cattle Plague Commissioners. "In the case of the best known ferment—yeast—its cells multiply by feeding upon the sugar in the liquid; alcohol and carbonic acid being their excretions. It is therefore probable that during the multiplication of the virus cells, they in a similar manner impoverish and weaken the blood, by feeding upon some element in it, whilst at the same time they excrete a poison to which the symptoms of the disease may be immediately due." Third Report, p. 187. In this twofold manner—by exhausting the constituents of the blood, and polluting it by excreta—we may rationally explain the occurrence of the febrile symptoms, weakness, and generally disturbed and deteriorated state of system which usually show themselves even before any distinctive symptoms of the particular disorder are noticeable.

So soon as the special symptoms of any contagious disorders are developed, the rapidly-produced germs of the virus are ready again to be given off, and to commence in other healthy bodies their career of destruction. Sometimes they are emitted from several different channels, as in the case of the cattle plague, which has been shown to be propagated by the mucus from the nostrils or mouth, by the discharges from the bowels, and even by the breath and the tears. Sometimes they appear to be confined more especially to one secretion, as in glanders to the discharge from the ulcers in the nostrils; in cow-pox from the vaccine pustules; in hydrophobia from the mucus about the mouth. In Influenza, catarrhal disorders, and probably also in pleuro-pneumonia, the specific morbid matters appear to be given off chiefly in the breath. In typhoid fevers and other such cases, where the digestive organs are mostly implicated, the dejections from the bowels probably contain the active germs in largest amount.

As the more familiar organic poisons, such as strychnia, prussic acid, hemlock, or ergot of rye, differ in their rapidity of effect, their potency, and their *modus operandi*, so likewise do these organized viri or contagions. Thus cattle plague poison, possibly from its greater diffusibility or tenacity of life, is more virulent than the virus of the mouth-and-foot disease, or of influenza; a very small dose suffices to disturb health, it travels uninjured long distances, it grows and multiplies even in the bodies of the healthiest cattle. Some of the contagious viri are so potent and destructive that no victim survives an attack—such are glanders and hydrophobia; others produce a mild and transient disturbance of health, such as vaccine pox, mouth-and-foot disease, and many cases of strangles: many confer an immunity from subsequent attacks, probably by removing from the blood those substances in which the germs grow and multiply. Some of the contagious viri only exert their reproductive powers when they are placed under the skin, or mucous membranes, or get access to the blood itself. The more diffusible and dangerous viri will travel, however, through the air, adhere to *fomites*, and gain access to the body of their victims through the respiratory membrane, or even through the digestive apparatus.—*North British Agriculturist.*

"HOOKS."—John Howie, of Forrester's Falls, in the County of Renfrew, makes the following inquiry: "I wish information from you about a disease, or supposed disease, called the Hooks, consisting of a piece of white gristle that grows upon the lower part of the horse's eye, which some people in our neighborhood contend should be cut off, or it will blind them in course of time. I have a two year colt that is affected as above. I took it to an Englishman who is allowed to be the best horse doctor around here; he says it does not need to be cut, and there is no such disease, and it will go away of itself. By inserting information on this matter in the CANADA FARMER, you will oblige the writer and many others in this neighborhood.

ANS.—"Hooks" are an imaginary affection. The *membrana nictitans*, or haw, an appendage of the eye that has the power to a great extent of protecting the eye-ball from injury, and also tends to remove any foreign substance that may become lodged in the eye, is often mistaken for an abnormal growth, and is in consequence sometimes rudely removed. In some instances the haw becomes enlarged, when, if it causes irritation, the eye should be fomented with tepid water daily, and a mild astringent afterwards applied, as five grains of sulphate of zinc dissolved in one ounce of water.

Poultry Yard.

Standard of Excellence in Exhibition Poultry.

BANTAMS.

GAME BANTAMS.

GENERAL SHAPE AND COLOR.

The same as in the corresponding varieties of Game Fowls.

POINTS IN GAME BANTAMS.

Smallness of size	2
Color	3
Shape of head and neck	2
" body and wings	2
" tail	2
" thighs, legs, and toes	2
Condition	2
	15

DISQUALIFICATIONS.

Cocks above 24 oz. or hens above 20 oz.; adult cocks unabbed, color of legs not uniform in the pen, birds not matching in the pen.

PEKIN BANTAMS.

GENERAL SHAPE—COCK.

Comb—Double, square in front, fitting close and straight on the head, the top covered with small points, with a peak behind turning slightly upwards.
Head—Small, round in front, carried well back towards the tail.
Beak—Short, slightly curved.
Eye—Full.
Wattles—Broad, rounded on the lower edge.
Deaf-ear—Flat.
Neck—Neat and taper, quite free from hackle feathers
Breast—Round, full, and carried prominently forward.
Back—Very short, perfectly free from saddle feathers
Wings—Ample, the points carried very low, almost touching the ground.
Tail—Square, similar to the hen, free from sickle or carved feathers, the feathers broadest towards the end.
Tail Coverts—Straight, round at the end and lying close to the sides of the tail.
Thighs—Very short.
Legs—Short, slender and very taper.
Plumage—Close, perfectly hen-feathered.
Carriage—Very upright and strutting.

GENERAL SHAPE—HEN.

Very similar to the cock. The comb and wattles much smaller, and the head neater.

GOLD-LACED SEBRIGHT BANTAMS.

COLOR.

Head, Face, and Wattles—Rich red,
Deaf-ear—White.
Plumage—Rich golden yellow, every feather laced with rich black, that is, having a narrow, even, well-defined rich black edge all round the feathers; the two colors distinct, and not shading into each other, the lacing of the same width on the sides as on the ends of the feathers.
Legs—Slaty blue.

SILVER-LACED SEBRIGHT BANTAMS.

COLOR.

Similar to the golden, substituting silvery white for the golden yellow ground color.

POINTS IN SEBRIGHTS.

Plumage most evenly and distinctly laced throughout	4
Purity of ground color in silver, and richness and clearness of ground color in golden	2
Comb	2
Tail	1
Smallness	2
Symmetry	2
Condition and general appearance	2
	15

DISQUALIFICATIONS.

Cocks weighing more than 20 oz., and hens more than 18 oz.
Cocks having either hackle, saddle, or sickle feathers.
Legs of any color except slate blue.

BLACK AND WHITE BANTAMS.

GENERAL SHAPE—COCK.

Comb—Double, square in front, close and straight on the head, the top covered with small points, with a peak behind, turning slightly upwards.
Head—Small, round, and carried well back towards the tail.
Beak—Short, slightly curved.
Eye—Prominent.
Deaf-ear—Flat and even on the surface.
Wattles—Broad and thin, rounded on the lower edge.
Neck—Very taper, curving well back, so as to bring the back of the head towards the tail, hackle full and long, flowing well over the shoulders.
Breast—Round and carried prominently forward.
Back—Very short, saddle feathers long.
Wings—Ample, the points drooping so as nearly to touch the ground, the secondaries slightly expanded
Tail—Full, expanded, well adorned with long curving sickle feathers, carried well up towards the back of the head
Thighs—Short.
Legs—Short, clean, and taper.
Carriage—Very upright, proud, and strutting

GENERAL SHAPE—HEN.

Comb—Same shape as that of cock, but very much smaller.
Head—Small, round and neat.
Beak—Small.
Eye—Full and quick.
Deaf-ear—Flat, and even on the surface.
Wattles—Small.
Neck—Short and taper, carried well back.
Breast—Round and prominent.
Back—Short.
Wings—Ample, points drooping.
Tail—Full, expanded, carried rather upright
Thighs—Short.
Legs—Short, clean and taper.
Carriage—Upright and strutting.

BLACK BANTAMS.

COLOR.

Comb, Face and Wattles—Rich bright red.
Beak—Dark horn color, or black.
Deaf-ear—Pure white.
Plumage—Rich black throughout.
Legs—Black, or very dark leaden blue.

WHITE BANTAMS.

COLOR.

Comb, Face and Wattles—Rich scarlet red.
Beak—White.
Deaf-ear—Pure white.
Plumage—Pure white, as free from yellow tinge as possible.
Legs—White, with a slight pink tinge on the back, and betwixt the scales.

POINTS IN BLACK OR WHITE BANTAMS.

Purity of white or richness of black	3
Smallness	3
Symmetry	2
Comb	2
Beak or face	2
Condition, and general appearance	2
	15

DISQUALIFICATIONS.

Cocks more than 20 ounces, or hens more than 18 ounces.
Legs of black bantams not black or dark leaden blue.
Legs of white bantams of any other color except white.

Do Poultry Pay?

THIS is a question concerning which much may be said on both sides. It is not often, however, that it is answered by the indisputable logic of facts and figures. Usually it is met by vague impressions. These sometimes array themselves on one side and sometimes on the other. We have met with people who were quite certain poultry are profitable, and others equally certain that they were a losing concern—neither of whom ever dreamt of keeping a balance-sheet. That enthusiastic agriculturist, Mr. J. J. Mechi, under date of Feb., 1868, gives the following interesting statement on this subject, which is very decisive in favour of poultry-keeping:—

"Having a conviction that poultry, like animals, consume according to their weight, I tested it by giving to a healthy, fine hen, weighing 6 lb., as much barley as she would eat. In seven days she consumed five half-pints. The very finest barley weighs 56 lb. per bushel; at that rate half a pint weighs 7 oz., so that the hen consumed 35 oz., or a trifle over 2 lb. in a week, having no other food. This is a third of her own weight weekly. A pig weighing 60 lb. (live weight), or ten times the weight of the fowl, would certainly consume quite 20 lb. of barley per week—or ten times as much as the hen; but see how great is the difference in value of the two for sale:—Pig, 4d. per lb. live weight; fowl, 9d. to 1s. per lb. live weight—wholesale price. But when the poultry are at large they consume many worms and insects, and therefore are produced at a smaller consumption of food than I have named. Altogether the advantage is so great, that the whole question of producing more poultry is a national and important one. If by a much larger supply the price were reduced one-half, they would still pay as well or better than sheep, bullocks, or pigs. Of course the same principle applies for poultry as for other farm animals. There must be good breeds, and no breeding in and in after the first cross. We import 500,000,000 of foreign eggs annually—to our disgrace be it said. It is a commonly received axiom that 56 lb. of barley will make 8 lb. of pork net dead weight, or 5 lb. will make 1 lb. live weight. Therefore 5 lb. of barley at 1d. per lb. (or average 40s per quarter) will make 1 lb. live weight of poultry, worth 9d. per lb."

Care of Young Turkeys.

THE first diet offered to turkey chicks should consist of eggs, boiled hard, and finely mixed, or curd with bread crumbs and the green part of onions, parsley, &c., chopped very small and mixed together so as to form a loose, crumby paste; oat meal with a little water may also be given. They will require water; but this should be put into a very shallow vessel, so as to insure against the danger of the chicks getting wet. Both the turkey hen and her chickens should be housed for a few days; they may then, if the weather be fine, be allowed a few hours' liberty during the day; but should a shower threaten, they must be put immediately under shelter. This system must be persevered in from three to four weeks. By this time they will have acquired considerable strength, and will know how to take care of themselves. As they got older, meal and grain may be given more freely. They now begin to search for insects, and to dust their growing plumage in the sand. At the age of about two months, or perhaps a little more, the males and females begin to develop their distinctive characteristics.

In the young males, the carunculated skin of the neck and throat, and the horn-like contractile comb on the forehead, assume a marked character. This is a critical period. The system requires a good supply of nutriment, and good housing at night is essential. Some recommend that a few grains of cayenne pepper, or a little bruised hemp seed be mixed with their food. The time of danger is over, and they become independent, and every day stronger and more hardy. They now fare as the rest of the flock, on good and sufficient food.

With respect to the diseases of the turkey, with them as with all other poultry, prevention is better than cure. The most important rules are: let the chicks never get wet, and encourage them to eat heartily by giving a good variety of food: yet to beware of injuring the appetite by too much pampering. Taking a pride in them is the great secret of success in the rearing of domestic poultry,—*Ex.*

Correspondence

County and Township Grants.

To the Editor of THE CANADA FARMER:

SIR,—In a recent number of your journal you gave some explanations of the New Agricultural Bill, in answer to the queries of a Secretary; perhaps you would be kind enough to explain a difficulty in the Act that occurs to a Treasurer. In section 48, subsection 1st, it is provided (among other things) that no Township or Horticultural Society shall receive more than *one-fifth* of the entire grant to any Electoral Division Society. Now the case is this: Township A deposits $260, B $168, and C $66, and to divide the grant ($700) in proportion to the amount deposited, A ought to receive $221.05; B $142.84, and C $56.11; but as one-fifth of the grant is $140, no more than that sum can be paid to any Township Society.

Now, the question is, how are such balances to be disposed of? In the above case $83.88 would be left in hand, for which, as far as I see, there is no provision for dividing it according to Statute. Is it to be paid to the other Township Society till its share comes up to $140, or is the Electoral Division Society to retain and use it, or will it be a "casual advantage" for the benefit of the

TREASURER?

NOTE BY ED. C. F.—The distribution of the three-fifths of any Electoral Division Society's grant to the townships in such division, is to be, to each, in proportion to the amount subscribed by its members, as compared with the amounts subscribed by the other townships in the Division, and as shown by affidavits of their respective Treasurers.

The provision objected to by "Treasurer" will not, in the case he cites, injuriously affect townships B and C; for, with the one-fifth limitation B will receive within $2.84, and C the full amount, of what they would have received if townships A and B had not been subject to such limitation, but had received the whole amount that, in the absence of the one-fifth limitation, each would have been entitled to, viz.: $221.05 and $142.84.

The Electoral Division Society, however, owing to the limitation to which townships A and B are subject, will reap the "casual advantage" of the unappropriated sums of $83.88 and $2.84, which townships A and B would have otherwise received. We do not suppose that in framing the provisions this result was contemplated, the intention of the limitation being to prevent one or two Township Societies obtaining a larger share of the grant than the County Society. When there are more than three Township Societies in any Electoral Division, the probability is that the whole of the three-fifths share of the grant will be appropriated by them.

Grass in Orchards.

To the Editor of THE CANADA FARMER:

SIR,—It is only by discussion that truth can be arrived at; and there is a communication in a late number of the CANADA FARMER which seems to call for some remarks, as it is quite at variance with the doctrines held by the majority of Canadian Orchardists. I refer to the article headed "Orchard Culture." Now, sir, it is almost an axiom among us that grass is bad for fruit trees, and that the more an orchard is cultivated the better the returns will be. This opinion has been arrived at by years of patient experiment, and by a careful noting of the experience of our American brethren, than whom there are no better orchardists in the world.

In a note to the writer lately, the leading fruit culturist perhaps in the Dominion said: "If you plant plums you must cultivate your orchard." Surely, what is good for plums cannot be bad for apples, and when we hear advice from such a quarter we cannot but think it safe to follow it. A conversation with an old and experienced horticulturist sustained this opinion, he taking strong ground against grass in orchards, while an actual experiment of a large orchard producing nothing while in grass, and giving liberal returns when broken up (which experiment I saw made), would go far to convince the most sceptical. But, although I state some of the arguments against the plan proposed, I should be far from wishing to dogmatize. I should like to have the subject thoroughly discussed, and the facts and arguments on both sides fully set forth. If we can seed down our orchards as soon as we plant them, and while getting a crop of hay each year, have our trees grow and produce better than by cultivation, by all means let us know it; or, if we can, by letting all the grass rot or be consumed on the orchard, produce equal returns, he will be a public benefactor who will establish the fact.

May 18, 1868. HURON.

P. S.—Is there any good pea-cutting machine? How has Collard's done the past season? If any of those who have used it would communicate the results of its use through the CANADA FARMER they would oblige.

Thorn Tree for Hedges

To the Editor of THE CANADA FARMER:

SIR,—I have seen so many charges preferred against my old friend the hawthorn, that I feel inclined to say a word or two in its behalf. But first let me say that when I left England to come here I was forty-six years of age, and twenty-five of those forty-six years I spent very much among the hedges. I have planted, plashed and trimmed hedges as much, perhaps, as any man in Canada, so that if I do not know a little about the business I must be a slow farmer indeed. The last three charges that I have seen against the thorn are by your correspondent, "R. W. S.," Woodstock. They are the following: First, the mice eat them; second, they are infected with wood-lice; and, thirdly, they do not grow thick at the bottom. Now, nearly one of the first things I wanted when I came to the farm on which I am now living was a thorn hedge. Having seen many young sprigs of Quick or Hawthorn in the bush, and having observed that they had plenty of prickles on them, and also that they were natives of this country, I could see no reason why they should not make a good hedge. So I gathered as much out of the bush as planted a hedge on each side of my garden. This is seven or eight years since. Now for the objections of "R. W. S." The mice during that time, I think, have eaten about six, that is all; but I rather think not even so many as that, and the few that were eaten shot out a number of young branches below the part where they were eaten; so that objection is not a very serious one. Perhaps about the same number have been infected with lice, but they were so little injured by them that I do not know now which they were. The last objection would be a great one if it were true; but as far as my hedge is concerned there is no force in it at all. For the benefit of your readers I will explain my plan of making hedges grow thick at the bottom. When you plant the hedge, set three roots in a foot, not further apart than that; cover the roots with good soil; let it grow two years or summers. The third spring cut it off, say the last week in April, to about an inch from the ground. Cut it off with a sharp knife, with an upward cut. Be careful in so doing not to loosen the root. In the Fall, after this, trim it down a little, not too much; take all the longer branches off, whether they be grown upwards or sideways; make it look snug and straight. But be sure you mind one thing; begin from this first trimming to form it into the shape of the letter A, sharp at top like a wedge; keep it in that form till you get it to the height you want it. One thing more; keep it clean of weeds, and you will have a hedge thick enough at the bottom. If any one doubts the truth of what I say, they can have an ocular demonstration if they will visit my farm.

STEPHEN NICHOLSON
Sylvan.

Mowers and Reapers.

To the Editor of THE CANADA FARMER:

SIR,—As the period is fast approaching when manual labour will be called into full requisition by the husbandman in securing the abundant growing crop, and it is to be feared that in some localities it will be inadequate to the task, it is important to utilize machinery as far as practicable. All admit, that were it not for the ingenuity and enterprise that has been employed in adapting machinery to the most laborious part of field labour, the agriculture of Canada would have been far below its present condition. Twenty years ago, in our palmiest days of wheat-growing, many farmers (the writer among the rest) would have grown it more extensively but for the difficulties of harvesting it. The "Canadian Reaper" has removed those difficulties, and makes what was before the severest labour almost a pleasure. There is still an effort being made to improve on these old and well-tried machines, by the addition of a self-raking apparatus. I would suggest to my brother farmers to see them tested before purchasing. The loss of valuable time in the middle of harvest with imperfect machinery is a serious drawback. With regard to Mowing Machines, they are no less useful, though not as yet come into such general use. Various unsuccessful attempts were made in the construction of this machine, and even after the cutting principle was brought to a tolerably good state, their prodigious weight and side draught made them a horse-killing implement to work, and prejudiced the mind against them. Perseverance has overcome the difficulty, and some of the Mowing Machines now manufactured might, I think, be termed almost perfect; and among that class you may number the "Cayuga Chief Junior," manufactured by Patterson & Bro., of Richmond Hill. This machine, for its adaptability to cutting all kinds of grass on the most rough and uneven surfaces, for strength, lightness of draught, and absence of side draught, surpasses all others that I have ever used or seen used, and I have been a close observer and anxious enquirer after truth in these matters. The old-fashioned "Canadian Reaper," and the "Cayuga Chief Junior Mower," furnish the farmer with two first-class machines, on which he may safely depend. Such is my opinion, based upon experience, and if of any advantage to my fellow agriculturists, I cheerfully tender it.

JNO. P. BULL.

York Township, June 5th, 1868.

WEEVIL.—A Communication from "A. J. B.," with a specimen of clay and insects, has been received, but too late for insertion in the present issue. It will appear in the next number, with remarks on the specimens, after we have examined them under the microscope.

AN OLD MAN'S HINTS.—A correspondent from Athol, who informs us that, though he has lived more than three-score years and ten, he now ventures to write with a view to publication for the first time, sends us the following hints:

THE THISTLE PLAGUE.—I have fought them for nearly fifty years, and am fully persuaded that all thistles cut when in full blossom, or rather just past bloom, are killed, and ploughing for the purpose of destroying them should be done at the same time. No seed, no thistle: three years without seed, and they would be exterminated.

THE USE OR ABUSE OF SALT.—I have seen a piece going the rounds headed, "Brine a Poison," and a French author quoted to prove it. Many of my neighbours also endorse the statement, saying that old brine should never be used. Now, my experience is that salt or brine may be used with safety under the exercise of proper judgment; but that it will kill anything that lives, whether man or beast, tree, shrub or plant, if improperly used. My father killed the first cow that I can remember with pickles saved in salt. A neighbour took a pail of brine, and gave his cattle a little sup; a large steer, being too greedy, got too much and died. Two others gave it to their sheep, and two to their pigs, with the same result, and so on to the end of the chapter. It is only the immoderate and injudicious use of brine or pickling salt that need be avoided. I use my old brine or pickle thus: Any spare brine in winter, I put on coarse fodder in summer; on nettles, thistles, elder-bushes, or anything I want to kill, and let the sheep grub them off. My best brine I boil, skim, and cool, then put on new pork, with the best results.

BLACK KNOT IN THE PLUM TREE.—A correspondent from Richmond Hill writes: "I am told that leached ashes are a certain cure for black knot. Mr. Welsh, of Thornhill, first observed that all his plum trees were affected with black knot, except one, around which some leached ashes had accidentally been thrown. Taking a hint from this, he placed leached ashes around the roots of all the trees, which are now smooth and healthy. As this is a time when thrifty housewives will be making soap, or will have just made it, I thought this a timely item for your invaluable paper."

WELLS.—A correspondent from Colborne enquires if we know any more economical way of obtaining water from below the ground than the old-fashioned way of digging and walling. "I have heard," he says, "of iron tubes being driven in the ground till water is obtained, but have never seen them in use." Can any of our readers give information to the point? We have seen accounts of the plan referred to in American papers, and have known the method adopted in the soft and uniform soil of the Western prairies, but have never heard of its introduction into Canada.

The Canada Farmer.

TORONTO, CANADA, JUNE 15, 1868.

The Provincial Exhibition.

THE prize list for the approaching exhibition at Hamilton, in the week commencing Monday, the 21st of September, has been prepared for circulation, and is now ready to be issued. The arrangements, as far as the Board of Agriculture are concerned, are well advanced, but a good deal yet remains in the hands of the local committee of what will properly fall to their share. There is plenty of time still remaining to arrange matters, and doubtless the City of Hamilton will do itself honour by making the most thorough preparations for the interesting occasion which is in prospect. The prize list, as amended this year, differs in few material points from that of 1867. The rules and regulations have been altered, and the programme changed, to adapt the latter to the year and the former to the new agricultural statute. An important variation, necessitated by the change in the law, is that entailed by the recognition of the Mechanics' Institutes and Fruit Growers' Associations, each of which will now hold its annual meeting during the exhibition week. The Fruit Growers' meeting has been arranged for Tuesday evening, the Mechanics' Institute meeting for Wednesday evening, and the annual meeting of the Association for Thursday evening of the week.

No changes have been made in the prize list for horses, but in cattle the prizes for all descriptions have advanced in the following ratio:—Cows from $20 the first prize, $12 second, and $8 third, to $24 first, $16 second, and $12 third; three year olds from $16, $10 and $6, to $20, $14 and $10; two year olds from $12, $3 and $5, to $16, $12 and $8; yearlings from $10, $6 and $4, to $12, $8 and $6; heifer calves from $6, $4, and $2 to $10, $6 and $4. These respectable additions will, if begetting no more competition, prove a healthy stimulus to an important branch of agriculture.

The Prince of Wales prize is given this year to the best herd of cattle, consisting of one bull and five female animals, all thorough-bred. The Ferguson Cup, formerly presented by the late Hon. A. J. Ferguson Blair, has been discontinued.

In sheep classes an increase of $55 in all has been made, $9 being added to the prizes for shearling ewes and ewe lambs, and $2 to the ram lamb classes.

In the Horticultural Department some details are changed, but altogether the amounts remain much as they were last year.

Some additions are made in the implement class, among them a land presser, horse pitch-fork, ditching machine, machine for sowing grass seed and for pulping roots, for all of which prizes are offered.

The Canada Company's prize for wheat is continued, the Association offering $40 as a second, and $20 as a third prize.

In the Arts and Manufactures department no changes of any note are made, and in the majority of instances the arrangement is continued.

The arrangement in the Fine Arts, though made last year, is not yet sufficiently known to make it unworthy of reference. For some time previous the classification of amateurs and professionals together was a matter of constant complaint. Amateurs alleged that they had no chance beside professional artists, and that if any encouragement was to be given the art of painting, and any inducement offered worth competing for, a distinction should be made. In accordance with these wishes, the Board of Arts last year separated the competitors into two classes, at the same time making sections in each for professional list, oil originals; amateur list, originals and copies; professional or amateur figure subjects; and the same in water colours. The separation proved acceptable last year, and will, we hope to see, make large additions to the exhibition under the same arrangements this year.

Judges in some of the classes of animals have been selected from the United States; the remainder will be named by the Committee of Societies.

Railway Gardens.

THE Grand Trunk Railway Station Master at Guelph, G. A. Oxnard, Esq., has set an example the present spring which we should like to see imitated all along that and the other lines of railway in the Dominion of Canada, having laid out and tastefully planted, at his own expense, a beautiful little garden adjacent to the Passenger Depôt. It is astonishing what a change this has made in the whole contour and influence of the place. Whereas before the scene had only an air of business and was purely utilitarian in all its belongings and surroundings, there is now an air of refinement and an appearance of beauty and elegance, whose influence is felt by all observers. The stone station-house and brown sheds have assumed a look of enhanced respectability, being affected by the garden very much as a man is, who already dressed in a good, substantial suit, gives himself the finishing touch by putting on a good hat and a nicely fitting pair of boots. Passengers who are waiting for belated trains beguile the weary moments by admiring the shrubs and flowers, and travellers beginning or pursuing a journey, get a glimpse of rural loveliness which reminds them of home. The town artisan beholds with pleasure the little enclosure, and thinks how easy it would be to get up such a scene of beauty in front of his own cottage door. Giles from the country, where grass and trees are abundant, reflects how readily he could make a pleasure garden on a far larger scale, and beat the little railway parterre hollow by a spacious lawn, an extensive shrubbery and spreading flower-beds on his own farm. Wives and daughters besiege husbands and fathers for leave and help to do something equally pretty where they live. The little railway

garden is thus not only a source of pleasure, but an educator. Railroads have educated us into promptitude, punctuality, and push; they have exerted mighty moulding influences on business; it is possible for them to give that dull scholar, the public, some lessons in æsthetics, and be an educator in the direction of rural improvement and home adornment. The question, will it pay? by which all railroad affairs are mainly settled, may, we think, be proved to be entitled to receive an affirmative answer without resorting to any very far-fetched argument. If people catch the contagion of taste and refinement, they will build better houses, import articles of adornment freight shade, ornamental, and fruit trees, and travel more under the influence of a desire to see the far-off loveliness of nature and art.

If these improvements are made, it must be, we understand, at the cost of the station-masters. Being subject at all times to promotion and removal, the encouragement to engage in this sort of thing is not great. Might not Railway Companies apply a stimulus in some way, either by affording inducements and facilities in this direction, or by giving a prize annually for the best laid-out and neatest-kept garden along their lines? At water stations it would be easy for companies to apply what would be the most striking feature in a railway garden, namely, a fountain. This could be fed from the tank and the flow carried back to the well or reservoir, so that there would only be the pumping to provide for—a comparatively small item.

Railway gardens are very common in England. Some of them are extremely pretty, and fix themselves in the recollection of the transient traveller. We have very distinct and pleasant memories of some we saw during a tour in England nearly seven years ago. Railway gardens are also becoming numerous in the United States. There are some very handsome ones in the vicinity of New York. On the line of the Erie Railroad, also on the Lake Shore Railroad between Cleveland, Ohio, and Erie, Pennsylvania, there are many tasteful depôts. An American exchange, referring to this subject, but more especially urging a better style of depôt building, remarks: "It is not to be supposed that all railroads can immediately rush into such landscape and architectural exercises; for it is a prime principle with them to make everything pay. But we submit whether pretty depôts, surrounded by nice lawns and gardens, do not go far toward making a road popular; and if popular, of course it pays."

There are very few railway gardens in Canada, but we hope the station-masters may have a run of horticultural fever, and then there will soon be more. Kingston and Brampton are the only places on the line of the Grand Trunk Railway where we remember to have noticed gardens. The Great Western Railway at Hamilton is beautifully ornamented in this way, and some time ago there was a very pretty little garden at Harrisburg, but the station-master during whose reign it flourished seems to have had a Gothic successor, who officiates

> "Near yonder spot, where once the garden smiled,
> And still where many a garden flower grows wild."

We hope more attention will be given to this matter by railway people.

New York Agricultural Exhibition.

It is now officially announced that the next exhibition of the New York State Agricultural Society will be held at Rochester, commencing on Sept. 19th, and open till Oct. 2nd, inclusive.

We commend the regulation referred to in the subjoined notice extracted from the *Journal of the N. Y. Ag. Soc.* A rule that shall render it imperative to close all entries some time previous to the opening of the exhibition is essential to the orderly arrangement of the specimens, and a timely adjudication of the prizes without hurry or confusion. The place appointed is eminently suitable and convenient of access, and the time will in no way clash with our own Provincial exhibition, which will be held during the week previous. The notice to which we allude is as follows:

"Attention is directed to the new regulation regarding entries. The entry books will be closed on Monday, September 14th (two weeks before the opening of the Fair), and no entries will be received after that day.

"This regulation is intended to insure the orderly arrangement of the exhibition, and to prevent the confusion and delay at the opening of the Fairs, which resulted from the reception of entries up to, and sometimes even after the time of opening. It is hoped that, under the new rule, the exhibition will be in order, and that the judges will be able to make their examinations and awards, in great part, on the first day, so that visitors on the second day may know what animals and articles have gained the premiums, and exhibitors may receive the benefit of their inwards—heretofore frequently not announced until near the close of the Fair.

"Entries may be made at any time until September 14th (the earlier the better), by letter addressed to the Secretary of the New York State Agricultural Society, Albany, N. Y., or personally at the Agricultural Rooms.

"The Premium List has been much enlarged, and the regulations (to which the attention of intending exhibitors is particularly directed), have been revised, and, in some other respects, amended.

"Copies of the Premium List and Regulations will be sent by mail on application to the Secretary as above, and may be had at the Rooms."

Report of the Secretary of the Michigan Board of Agriculture.

We have received a copy of his Report for the year 1867 from Mr. Sanford Howard, the Secretary of the Michigan Board of Agriculture. It is a thick octavo volume of nearly 500 pages, and is full of most valuable and interesting information, as a brief summary of its contents will at once indicate. The first fifty pages give an account of the State Agricultural College and its various operations during the past year. The condition and progress of this valuable institution are most satisfactory. Among the investigations conducted in connection with the College were a series of experiments on sheep-feeding, and also some trials with various fertilizers, the results of which, however, were defeated by an inroad of swine, showing the utter disregard of these unworthy republicans for authority or science. The Report next gives a statement of the characteristics of the past season in Michigan; the yield of crops, with a special record of certain new crops, viz., sorghum, hops and peppermint. The injurious insects that work such havoc in the farmers' fields, the Potato-Bug and Canker-Worm particularly, receive their share of notice. A very full report is given of the climate and general characteristics of that newly opened portion of the State, known as the Grand Traverse Country. The important subject of cheese factories, and the progress of the associated system of dairying in the State, are duly considered. Reports from Agricultural Societies occupy a large portion of the volume; and besides these various subjects of comparatively local interest, there are in the work some valuable papers that will be acceptable to agricultural readers everywhere. Among those may be mentioned the following: Agricultural Societies, their proper objects and right management; Irrigation; Cross-breeding of Sheep, by Wm. Spooner; Principles of Hay-making, by Dr. Voelcker; The Dew of Heaven—Influence of Forests, by Cuthbert W. Johnson; Food, by J. B. Lawes and J. H. Gilbert; and a most valuable dissertation on the Diseases of Cattle, by Professor Gamgee. The whole forms a noteworthy contribution to the agricultural literature of the day, and should be on the shelves of every well-furnished library in that department.

DEVON HERD BOOK.—Mr. H. M. Sessions, South Wilbraham, Mass., announces the early publication of the second volume of the American Devon Herd Book, containing over 600 pedigrees.

The Season.

We have still to chronicle favourable weather, and the promise of good crops. Much rain has fallen since our last issue, too much, indeed, for low-lying and undrained land, but none too much for land that is high or properly drained. Any excess either in the direction of wet or drought proves the importance of drainage. Drained land endures the want of rain much better than undrained, while it soon recovers from the effect of superabundant moisture. In some quarters we hear complaints of the wire-worm as very destructive in wheat fields, but with this exception the wheat report is most encouraging. Hay is now sure to be a good crop. Pasturage is abundant. Nature smiles with verdure, and is purpled with flowers. The land flows with milk and honey. Grain, grass, fruit, beef, mutton, and all farm products, bid fair to be abundant.

Wool.

The market is at present in a very dull state, and the prospect for dealers seems anything but encouraging. Stocks everywhere are large, and since the imposition of the heavy duties there is no outlet for our surplus supplies. The depressed condition of the manufacturing interests precludes the possibility of there being much demand at home, and therefore prices are expected to rule low. From 23cts to 25cts are the prices now paid by dealers for wool, and it is not expected that these rates will advance. Dealers will only pay the above prices for clean, good wool—indeed, it is now difficult to find a buyer at any price for dirty wool, or wool only partially cleaned. At any rate, much lower prices have to be accepted for any fleeces not properly cleaned.

Officers of Agricultural Societies for 1868

PAKENHAM BRANCH.—President, Andrew Dickson; Vice-President, Young Scott; Sec. & Treasurer, Alex. Fowler. Directors:—Samuel Dickson, Charles Dunlop, James Woods, William Dickson, Junr., John J. Browne, John A. Gemmill, Robert Elles, Thomas Bowes, James Elies.

PRESENTATION.—The members of the County Agricultural Society of South Ontario presented to their President, John Shier, Esq., on the 25th of May, a very handsome and valuable gold watch, as a mark of their respect and esteem.

TREATMENT OF EMIGRANTS.—We were very sorry to read in the *Globe* of June 10th a letter signed "Emigrant," complaining of the treatment which the writer and fellow-travellers had received on board ship and on their arrival in this country, treatment which the writer averred induced a number of his companions to change their destination from Canada to the United States. We hope and believe there must have been some misunderstanding in the case; for we cannot suppose that the chief authorities could be aware of the circumstances. Subordinates sometimes, in every department, give themselves fearful airs, and recklessly sacrifice their employers' interests to their own selfish whims or personal advantage. Such a statement as that to which we refer is calculated to damage the country in the estimation of neighbours, and of those especially who are contemplating a removal from the fatherland to this. Every possible kindness and assistance should be rendered to emigrants arriving here; railway officials, emigration agents, and all authorities concerned, should be especially careful to mitigate the unavoidable hardships and perplexities of the new comers, and to show them that they are welcome amongst us. We hope the letter referred to will receive some attention, and call forth a satisfactory exculpation of the chief authorities concerned.

Agricultural Intelligence.

Emigration from the East End.

The London *Times* of the 22nd ult., says: The committee of the East-end Emigration and Relief Fund are prosecuting their work of emigration to Canada as a means of relief for the distress at the east of London with some vigour. It will be recollected that on the 16th of April last they sent 163 emigrants to Canada in the St. Lawrence, the first steamer leaving the Thames for that port this season, and this was yesterday followed up by the despatch of another party of 167 souls, in the steamship Thames, to the same destination. These people have all been selected with great care from among the unemployed who have been thrown out of work in consequence of the slackness in the iron ship-building trade on the Thames, by a committee of gentlemen in Poplar, and in all cases attention has been paid to the selected candidates for emigration fulfilling the following requirements—that they shall have been long resident in the district; that their characters bore strict investigation; that they were not in the receipt of parochial relief; and that they had not refused work or been on strike. In all cases in which any doubt arose, personal application was made to the last employer of the candidate, and the characters of many among them have been certified by the recommendations of Messrs. Green, Samuda Brothers, Blyth, and other large employers of labour. Mr. Dixon, the Canadian Government agent, expressed his high approval of the appearance and bearing of the men, all of whom may be said to be in the prime of life, and stated his opinion that, provided they were steady, they could not fail to obtain employment in Canada, and do well there. It is particularly satisfactory that the younger members of these poor families (for all the emigrants are in families) have some prospect in life open for them. This seemed the great hope of the mothers. One poor woman was heard to say, "It's the boys I'm thinking of; I was afraid they would be disgracing me by idleness in Poplar." For the girls, too, there is much hope; all above 14 are sure to meet with immediate employment on arrival in the Dominion. The arrangements were satisfactory. After mustering the passengers and ship's company, and before reaching Gravesend, dinner was served to the emigrants, a fact they appeared to appreciate. The Canadian mail in the morning had brought letters from Mr. L. Stafford, the chief emigration agent at Quebec, announcing the arrival of the St. Lawrence on the 7th inst., and reporting the disposal of the emigrants, whom he describes as a "well-behaved and healthy-looking lot of people," and respecting whom he promises a full report when they are finally settled.

Preserving Meat.—The Gamgee Process.

Professor Gamgee, the distinguished Veterinary Surgeon, whose name has been so prominent before the British public and the world in connection with the ravages of the Rinderpest, and who is also the author of one of the best modern works on veterinary science, has recently visited the United States in order to introduce his newly invented method of preserving meat fresh, with a view of procuring from Texas and other parts of the continent an increased supply of fresh meats at moderate prices for the population of Great Britain. The *American Agriculturist* thus speaks in reference to the matter:—

"The process by which the meat is cured is patented in this country, and consists of causing the animal to inhale carbonic oxide gas until it loses consciousness, when it is killed and bled. The carcass is then quickly dressed, and while still warm, exposed a short time in a chamber to an atmosphere of the same gas, mingled with a little sulphurous acid gas. These gases, especially the former, combine with all the oxygen in the system, and take away all that enters the meat through the absorption of air. This very important discovery, which is the result of years of study, may be of incalculable advantage to the people of this country and of the old world. If Texas beef can be placed in our markets at five or even ten cents per pound, both the raiser there and the consumer of beef here will be greatly benefited. It seems almost as if the time might soon come when beeves, and sheep, and hogs, will no longer be packed in close cars, transported for days and nights in suffocating heat or piercing cold, driven through our crowded cities, feverish and excited, starved and famishing for drink, to be thus slaughtered; but killed within sight of their own pastures, and their flesh, preserved by this process, transported like any other merchandise, to be sold and used at any time within six or eight months. Experiments will soon be made of transporting "Gamgeed" beef and mutton from some of our Western States and from Texas, and our readers shall have reports of the success. These experiments or tests are taken in hand with great zeal by several gentlemen of large means and entire responsibility, so that we may hope for speedy and accurate results. It is but fair to add that this interesting discovery of the action of carbonic oxide on fresh meat was made in pursuing investigations having for an object the furnishing of healthy meat, at a cheap rate, to the population of Great Britain.

Goderich Salt Mills.

A correspondent of the London *Advertiser* says, within the past two weeks two salt wells have been completed. A stratum of fine salt, 15 or 20 feet thick, has been pierced at the depth of 1,000 feet. The first of these, called the Huron Well, was commenced on New Year's day, and finished in four months and about six days. The contractor, Mr. Morrison, having pushed on the work with vigour, was enabled to perform the work in one-half the time taken by him last year at the Ontario Well. The second, which is called the Victoria Well, owned by Captain Dancy, Messrs. Butler, Sheppard and Strachan—all citizens of Goderich—was completed in exactly four months. Taking into consideration that they have superintended the work themselves, at the same time being inexperienced drillers, this is decidedly the best time yet made in boring for salt. A third well—the Dominion—is now at the depth of 1,000 feet, and it is expected that a week or ten days will suffice to reach the salt rock. The contractors, Messrs. Olin & Bigelow, commenced the well on the 6th or 7th of February—a month later than either of the others—drilled a 5 inch hole for 500 feet, and a 4½ inch hole for the rest, and should nothing hinder them, they will finish the well in shorter time than was taken at any of the others. There is yet a fourth well sinking within the corporation of the town, the Tecumseh. The contractor was unfortunate at the commencement, getting the tools fast, and after spending two or three months in endeavouring to extricate them, he had to abandon the task and start a new hole. He is now getting on fairly, but it will take him a long time to complete the well. Across the river are two wells in course of being sunk, one of which will be completed soon. This makes eight wells in all; a number quite sufficient to supply the demand for salt in Canada for many years. The necessary buildings and furnaces for the manufacture of this article are rapidly proceeding, and will be in operation within three months

The Latest Improvement in Horse-Training.

For the last four days, Dr. H. S. Rary, the celebrated American horseman, has been giving his lectures and conversations at the Magog House, and in all candour we must admit that his mode of handling wild horses is wonderful. Although his method of shoeing and treating lameness is new, it is in accordance with common sense and commends itself by the best of all tests, experience. A young horse of our own badly affected by clicking or striking the front feet with the hind ones, was entirely relieved by the Dr. A horse owned by Mr. Harkness, lame from gravel, was enabled to move off glibly, by being shod with one of the Dr.'s new gravel shoes. A mare, lame from corns and knee sprung, owned by Mr. J. Griffith, was relieved in a few hours. His new theory respecting the bots was clearly illustrated on Thursday by the stomach of a horse, where the bots could be seen in their natural state as an organ of the stomach. The Doctor appears to be governed by nature's laws in all his dealings with the horse. After seeing him operate, and hearing his illustrations, we can readily appreciate the advice of a Montreal contemporary, to go and learn a lesson from nature by attending the Doctor's exhibition. A very wild colt belonging to J. G. Robertson, Esq., after a short training, followed the Doctor up three flight of stairs to the Town Hall, without difficulty.

Mr. Rary will be at Compton on Saturday; at Coaticook on Monday and Tuesday; and at Stanstead the remainder of the week.

We advise all interested in the raising of horses, or who have horses difficult to manage, to attend his lectures.—*Sherbrooke Gazette.*

☞ The hop plantations in Kent, England, have never been known to present so forward an appearance at this season of the year.

☞ The wheat crop in the south of England is looking very promising. It is estimated that it will yield three sacks an acre more than last year's crop.

☞ The weather reports from the agricultural districts of France continue to be favorable.

☞ X. A. Willard says, in the *Country Gentleman*, that more wheat was sown last Fall and this Spring in the dairy region in New York than for many years before. He thinks this approach to mixed husbandry desirable. So do we.

WHEAT CULTURE IN NOVA SCOTIA.—The Nova Scotia *Journal of Agriculture* says: We have had a remarkably severe winter, and the springtime has been a cold, wet, backward season. Our farmers all hope that they may never see its like again. Early in April, however, a good deal of wheat was sown on fall-ploughed land. More wheat has been sown this season than for many years. The Board of Agriculture has distributed, at cost price, 360 bushels of the finest Fife wheat that could be obtained in Western Canada. Last year a large quantity was distributed all over the country in the same way. It turned out so well that nearly all of it was kept for seed. In addition to these sources of extra seed, we know that several merchants imported seed wheat this season, and that the demands upon the Board of Agriculture were far from being met by the supply on hand. It is evident from all this, that a decided attempt is being made to regain our lost ground as a wheat-growing country.

FREE GRANTS.—The Peterborough *Review* says that the free grant system is to be at once extended to the entire "back country." Portions of the Townships of Cardiff and Monmouth are to be thrown open to settlement, and as soon as lists of the lands can be prepared, and other arrangements completed, the vacant lands in other townships, both on the Burleigh and Bobcaygeon roads, are to be placed under similar regulations. The Burleigh road is to be completed as far as the Monck road this season; besides that, the unpatented lands in the old townships, if not settled for, are to be forfeited, and resold by public auction. We hope it is true that the free grant system is to be extended to the "back country" of the County of Peterborough, though we have not as yet seen any advertisement whatever of the lands mentioned by our cotemporary.

DRAINAGE.—We observe that a project for draining some of the swamp lands in the County of Lambton is under consideration. It is said, on the authority of an engineer, that the well-known Brooke swamp can be drained in such a way as to render fit for cultivation some 30,000 acres of deep, rich, loamy, alluvial soil, now utterly useless for agricultural purposes. If that is true, the profit of draining the swamp will be very considerable. The effect will be to create a property worth, at the present value of good wild land in that part of the country, not less than a quarter of a million of dollars. There are other localities in the Province where large tracts of swamp land might be reclaimed by a little draining, and in nearly every case such land, when it is made fit for cultivation, proves of the best quality.

SHORT-HORN BULL, "DUKE OF SOLWAY."—We learn that Mr. John Snell, of Edmonton, has sold to Mr. Archibald McNee, V. S., of Perth, Co. Lanark, for $200, the Short-horn Bull, "Duke of Solway," eighteen months old. "Duke of Solway" is said to be a young animal of rare merits, and combines the blood of some of the best stock in the country, being sired by "Duke of Bourbon," the winner of the sweepstakes prize at the last Provincial Exhibition at Kingston. His dam, "Mary Grey," by imported "Baron Solway," is one of Mr. Snell's choicest cows; she was winner of the second prize as a yearling at the last Provincial Fair at Hamilton. The "Duke," if the people of Lanark avail themselves of his services, will be sure to make his mark in the improvement of the stock of the county.

Mr. Snell, in a recent communication, says that "he feels that he owes to the advertisement in the CANADA FARMER the satisfactory sale of this bull, as well as other sales that he has recently made."

Fruit Growers' Association of Ontario.

A MEETING of the Directors of the Fruit Growers' Association was held at Hamilton on the 20th May, in the County Council Chambers. The President, W. H. Mills, Esq., was in the chair.

It was resolved that the next meeting of the Association be held at Toronto, at the call of the Secretary, who should communicate with the member for Toronto regarding the time of meeting.

Resolved, that the following persons be nominated for judges of fruit at the Provincial Exhibition in September next, viz., W. Holton, R. N. Ball, Rev. R. Burnet, Charles Arnold, George Leslie, D.W. Beadle.

Resolved, that the Association respectfully suggest to the Board of Agriculture that, in view of the probable large exhibition of fruit, not less than six judges be appointed in the fruit department, three of whom shall be assigned to the amateur list, and three to the professional list.

Resolved, that the Annual Meeting of the Association shall be held in the City of Hamilton, on Tuesday, the 22nd day of September, at 7 o'clock, p. m., at the Court House, Prince's Square.

Resolved, that the Secretary cause one thousand copies of the Constitution and By-Laws to be printed for the use of the Association, provided the expense do not exceed $15.00.

Resolved, that an honorary medal be awarded to the originator of any new fruit, which shall have been tested according to the regulations prescribed for ascertaining the merits of such fruit.

Resolved, that any person competing for the honorary medal, shall place at the disposal of the Directors one dozen plants, or, in the case of apples or pears, one dozen scions, of the variety to be tested, which shall be placed under their direction in different localities, with the understanding that the parties so receiving them shall not disseminate the new variety.

Resolved, that any member wishing to exhibit a new fruit on his own grounds, shall notify the Secretary of his desire, in time to enable the Directors, in their discretion, to appoint a committee to visit his grounds, and examine and report thereon in writing to the Directors, and that any person desiring to receive such visit shall, in his request to the Secretary, state the kind of fruit he wishes to have examined, its origin, and the points of excellence.

Resolved, that the Association hereby offer a discretionary prize of forty dollars for the best essay on the apple and its cultivation, as applicable to the Province of Ontario. The essay is not to exceed eight printed pages, octavo, to be forwarded to the Secretary of the Association, D. W. Beadle, St. Catharines, on or before the first of September next, the essay to bear a motto, accompanied with a sealed note containing the name of the author, upon which note the same motto shall be endorsed.

Resolved, that the Committee appointed to examine new fruits, shall, in their report thereon, set forth the particular excellence of any of the fruit, and specially its quality as to hardiness, productiveness, flavor, and market value.

Resolved, that all persons having fruits which they wish to have examined by the Association, are requested to bring them in person to any of the regular meetings, and place them upon the exhibition tables; and all such fruits as shall be found to be of superior excellence, shall receive honorable mention in the Reports of the Association, and through the CANADA FARMER.

Resolved, that one hundred copies of the Declaration be printed, to be used in obtaining members.

Resolved, that the Association hold themselves at the disposal of the Board of Agriculture to assist them with a Committee of arrangement and classification of fruit during the ensuing exhibition at Hamilton.

Resolved, that the following names be added to the Fruit Committee, viz., James Dougall, nurseries, Windsor; —— Adams, Sarnia; W. S. Stripp, Gladstone, Ontario; Archibald McKellar, Chatham; G. W. Scribner, Chatham; A. P. Farrell, Cayuga; Dr. R. R. Smith, Komoka; Wm. Saunders, London; —— Partridge (lawyer), London; A. W. Dedman, Delaware; James Grey, Woodstock; Geo. Ferguson, Port Stanley; Luke Bishop, St. Thomas; J. B. Gordon, Goderich; A. B. Bennett, Brantford; W. A. Smith, Paris Road; A. Morse, Smithville; W. F. Murray, Clinton; James Young, Georgetown; Moses Kraft, Waterloo; Dr. Bolby, Berlin; George Morton, Guelph; A. F. Scott, Brampton; David Allan, Guelph; Norman Hamilton, Paris; Jeremiah Hagerman, Oakville; Thomas Chisholm, Milton; Oliver Springer, Wellington Square; Dr. Dixie, Credit P.O.; W. F. Clarke, Guelph; Peter Trout, Meaford P. O.; Dr. Luther Cross, St. Catharines; Nathan H. Pawling, Port Dalhousie; Gago Miller Virgil, Niagara; M. Y. Keating, Jordan, Ont.; S. J. J. Brown, Niagara; Zenus Lewis, Clifton; W. A. Johnston, Ameliasburgh; J. D. Humphreys, Toronto; —— Racy, Mohawk; Rev. R. Robinson, Owen Sound; D. Resor, Markham; J. M. DeCourtenay, Amherstburgh; R. N. Ball, Niagara.

Resolved, that Messrs. Miller, Burnet, and Beadle, be a committee to examine and report upon Mr. Arnold's raspberries.

Resolved, that the President be authorized in his discretion to appoint a committee to examine and report upon such other fruits as may be called for before the next meeting of the Board of Directors.

The Board adjourned to meet at call of the President.

Oil as a Remedy against Insects.

MANY years ago we were interested in some experiments made by some medical students on the destruction of insect life by oil. The slightest drop of sweet oil, put on the back of a hornet, beetle, bee or similar thing, caused its instant destruction. We were told the breathing pores were closed by the oil, and life was literally smothered out. In after life greasy water was always a favorite mode with us of destroying insects, and we have repeatedly urged it upon the readers of this journal. Yet we are astonished to find how little the hint has been acted on. Almost every day we meet people who ask how to destroy this insect or that, and our drawer is filled with similar inquiries; and to all the idea of grease or oil seems as new a one as if we had kept the matter a profound secret.

Of the millions of people in the United States, how few are there who would not "give anything," as they say, to know how to keep away the cabbage fly from their seed beds; yet about a tablespoonful of coal oil put in a common garden water-pot of water, sprinkled over the seed bed, when the little jumping beetle is noticed as having appeared, will instantly destroy the whole brood.

A correspondent of this journal recently gave us an article on the virtues of coal oil in killing scale insects. We have repeated the experiment on some Daphnes with entire success.

In short, we have no doubt that coal oil, well diluted with water, is death to all kinds of insects, and there is no reason why it should not be in as general use as tobacco is for killing aphides—more valuable, in fact, because it can be applied in so many cases where smoke cannot.

One great point in favour of coal oil is that it acts as a manure to vegetation, while dealing out death to insects. We have seen cabbage beds nearly destroyed by the cabbage fly, have the whole crop of beetles destroyed almost instantaneously; while in a few days afterwards the plants, as if by magic, would cover the bed with luxuriant leaves.

We do not believe that the undiluted oil would prove injurious to the leaves, but such extravagance is unnecessary, as the small quantity we have given is effectual.

No doubt the egg-plant fly, and all insects that can be reached by the oil, can be destroyed.

There is scarcely one of our readers to whom we are sure this hint alone will not be worth many annual subscriptions.

We may add that any oil is as good as coal oil, but that being likely to be more easily obtained when wanted, is recommended; also, care must be used to keep the water in the pot stirred when used, so that a portion of the oil gets out as the water runs, otherwise the oil floating on the top of the water will stay there till all the water goes out and only the oil be left for the last. For this reason a syringe, in many cases, will be preferable to the water-pot, as the oil and water will have a better chance of getting out.—*Gardeners' Monthly.*

Currants and the Currant Worm.

VERY few growers of the currant have escaped the ravages of that vile pest, the currant worm or caterpillar. There are a few localities which the insect has not reached, portions of Center county, (Penn.) being among the number. The currant bushes in the neighbourhood of the Pennsylvania Agricultural College, have, as yet, completely escaped. There are, doubtless, other localities equally favoured, and it has occured to us that in such places, the growing of both the fruit and the young plants might be a profitable business. Where the leaves are not injured the wood ripens more thoroughly, and is more healthy, and plants raised under such circumstances would, doubtless, be more valuable.

The currant worm is easily kept under by the use of hellebore, but to those who dislike the trouble of even this remedy, we would suggest the black currant, which we think deserves a more general introduction than it has yet obtained. Some persons object to its strong odor. To such the variety known as Black Naples might prove more acceptable. As a fruit for preserving, the black currant has few equals. Jam made from it is unrivalled in cases of slight sore throat, and we have seen the black currant, fresh from the bushes, used in dumplings or plum puddings instead of raisins, and with very little deterioration in the quality of the article produced. When cooked, the black currant loses somewhat its offensive odor.

We have no faith in wine made from any fruit except the grape; but to those who live in high latitudes, and whose thoughts have been turned towards "wine plants," we would say that the black currant makes a—shall we say wine?—almost equal to some varieties of port—better than a good many samples of that article, and far superior to the stuff made from rhubarb, elderberries, raisins.—*Country Gentleman.*

☞ Every man who plants a shade tree in Worcester, Mass., is paid one dollar by the municipality.

☞ Fuchsias should be shaded from the mid-day sun. It is a good time now to make cuttings and propagate,

☞ Herbaceous plants, as soon as they have done flowering, may be easily propagated by cuttings. These should be planted in a cold frame in a mixture of sand and loam, and kept shaded until roots have formed.

☞ Tomatoes will bear more abundantly, and occasion the least trouble, if the ends of the shoots, just beyond the fruit, are pinched off. A surface mulch of rotten manure, and if a dry time, frequent watering, well repay in increased size and abundance of fruit.

NEW-MOWN GRASS FOR MULCHING.—Nothing that I have ever used equals new-mown grass for mulching newly planted trees or for placing among strawberry vines. It keeps its place, is clean and neat, leaves no seeds, and creates no fungi, as is often the case with old tan bark or rotten wood.—*Horticulturist.*

DWARF APPLE STOCKS.—Some of our nursery-men advertise dwarf apple trees "on Paradise stocks." These, Dougall of Windsor, in the "Fruit Culturist," says, are "unsuitable for this climate," and "comparatively worthless." We should like to have the opinion of other experienced fruit-growers on this point. Our own little experience inclines us to think the above condemnation too sweeping. There is nothing in our garden we admire more than the diminutive apple bushes, grown on Paradise stocks. They look very pretty, bear wondrously, and so far, appear quite as healthy as the half-standards on Doucain stocks.

Entomology.

The Plum Curculio.

(*Conotrachelus nenuphar*, Herbst.)

THE havoc committed by this terribly destructive little insect among the fruit of not only the finest varieties of Plums, but also of Cherries, Peaches, and even Apricots and Apples, must be only too well known by the majority of our readers; the origin of the evil, however, is not so often seen as the widespread ravages that he commits would lead one to expect. We purpose, therefore, to give a short account of the "Little Turk," as he is often styled from the crescent-shaped mark he makes on fruit.

The Curculios, or Snout-beetles, differ from almost all other beetles in the peculiar prolongation of their heads in the form of a snout; sometimes this appendage is as fine as a hair, at others as broad as the rest of the head; sometimes again it is as long as the whole body, at others it is quite short and inconspicuous; in some species it has the appearance of an elephant's trunk. On this snout, which is really a part of the head, and not a separate organ like the beak or sucker of a bug, or the proboscis of a housefly, are situated the antennæ, and at the top of it the eyes, the end terminating in the organs of the mouth. Our foe, the Plum Curculio, differs from all other Canadian Curculios in having a narrow, black, shining hump on the middle of each wing-cover, and behind these humps a yellowish spot, which is sometimes enlarged into a band across the wing-covers. It is about one-fifth of an inch long, exclusive of the snout, which is about a quarter the length of the body. Its general color is ashen black.

As soon as the young fruit becomes fairly developed, the Curculio begins its work. Our seasons, of course, vary considerably from year to year, but we may as a rule begin to look out for this insect about the first week in June, when it commences to infest the trees, and deserts its winter hiding-places. This year we found some specimens under rhubarb-leaves that had been left a few days on the ground near the plants from which they had been taken, on the 26th of May; some years ago we found one in an old gall on a hickory tree as early as April 20th. Various American writers relate their having found them in November and March, and Dr. Trimble says that he found some specimens under the shingles of a roof late in the fall, and in the chinks of stone walls and under a scale of bark in early spring. Hence we may infer that they pass the winter in their perfect state, remaining torpid like a large number of other insects, until the warm weather bids them wake up and perform their allotted work. The female it is that makes the crescent mark on the fruit, an operation which is thus described by Dr. Trimble in his elaborate work on the Curculio and Apple Codling Moth:—"The semi-circle or crescent-shaped mark is made by the end of the proboscis, and merely goes through the skin. This part of the process, while the fruit is young and tender, is soon finished, sometimes not taking more than two or three minutes. From the centre of the concave part of the crescent, the proboscis is next introduced under this cut skin, and there it slowly works, cutting its way until it can reach no further. The end of this cell or cavity is now dug out or enlarged, to make it a suitable receptacle for the destined egg. The insect has an instinct which teaches her that the surroundings of this cavity must be so deadened that no subsequent growth of the fruit at this part shall press upon that delicate egg and crush it. The preparation of this cell is much the most tedious part of the process, usually taking about fifteen minutes, though sometimes half-an-hour. During most of this time, the Curculio will be found in a pitching position, and with her proboscis entirely buried; looking as the woodcock does when boring for food in the soft ground. This cavity finished, she turns round and deposits an egg at its orifice; then assuming the former position, very quietly pushes that egg with her proboscis to its destined place. Next the crescent-shaped cut is plastered up with a gummy substance that holds the cut edges together for the time being; probably an instinctive precaution against the weather or insect enemies, that might endanger the safety of the egg." This process is repeated on one plum after another till the whole stock of eggs is exhausted. After a few days, the egg hatches out and produces a little white grub without legs, that bores into the flesh of the fruit, and causes its final destruction. After some weeks the injured fruit falls to the ground, and then the grub, being full-grown, works its way out, and enters the ground, there to complete its changes into the pupa and perfect states. The beetles emerge from the ground in August and September, sometimes even a little earlier. The only fruit that does not fall to the ground when thus attacked appears to be the cherry.

Such is a short life-history of this very destructive insect; and now let us consider what remedy there is for it. We need not dwell long upon this, as a correspondent, "Fruit-Grower," in our last issue, gave an account of the very best remedy there is, viz., jarring the trees and destroying all that fall. For full particulars we refer our readers to his excellent and timely letter. We may add that all fallen fruit should be gathered regularly, and not left for any length of time on the ground, and then be either burnt or fed to pigs. By employing these two methods, and persevering in them, a very large proportion of one's fruit can be saved, even though one's neighbours do not look after theirs, but cultivate fresh crops of Curculios for the annoyance of the more thrifty. If all fruit-growers would only unite in employing these simple methods, the Curculio would speedily be banished from our midst, or at any rate be reduced to very insignificant numbers. May we beg that all our readers will this year give the plan a fair trial, save their fruit, and let us know the result?

A Strawberry Bug.

FOR an entomologist to lay claim to infallibility would be absurd in the extreme, since he has to deal with a race of animals which is said to embrace many times as many species as all the rest of the animal creation put together. While, then, we endeavor to be as accurate and correct in our statements as possible, we, of course, do make mistakes sometimes; one of these has lately been very kindly pointed out to us by Mr. Riley, the State Entomologist of Missouri, whom we have the pleasure of numbering among our correspondents.

In the CANADA FARMER for Aug. 1, 1867, (vol. iv, page 238), we gave an account of what we took to be a small *beetle* infesting Mr. Arnold's strawberry plants at Paris, Ont.; this insect turns out not to be a beetle, but a *bug*, though it is uncommonly like a beetle. What we took to be the connate wing-cases, covering, to our surprise, wings for flight, turn out, on more minute inspection, to be the immensely developed scutellum (the triangular piece that separates the wings on the back) of a singular family of bugs, called from this peculiarity *Scutelleridæ*. We have never devoted ourselves to the study of the order *Hemiptera* (true bugs) so much as to that of some of the other orders of insects, and thereforo have but little acquaintance with its classification; nor do we know of any work which treats upon the American species of the order in particular; we are unable, then, to say whether our species is the same as that sent to Mr. Riley by his correspondent, viz., *Corimelæna lateralis*, Fabr., though we have little doubt that it belongs to the same genus. If Mr. Arnold should find any more of these insects upon his strawberry-plants this year, we beg that he will favor us with a good supply of specimens, that we may be able to send some to our correspondents and have the matter set at rest.

Insects on Plum Trees.

"J. J., Campbellford, Ont.," writes as follows:—"Please inform me what it is that causes the fruit of the common wild plum to swell up almost immediately after blossoming, while the tame ones invariably escape? The first time I noticed this disease was about four years ago: I enclose a few specimens of the injured fruit. You will also confer a favour by giving a description of the Curculio; it has not made its appearance here as yet, to my knowledge, unless these curious-looking little creatures which I enclose are specimens of it,—I took them off a plum tree to-day. Please let me know what they are."

We have frequently noticed the disease referred to in wild plums, but do not know its nature or origin. Whether it is the work of an insect or not we cannot say, but we shall endeavor to find out this season. The request for information about the Curculio has been anticipated by the foregoing article, which we prepared as appropriate to the season. The insects enclosed, together with the plums, were crushed "as flat as a pancake" in their transit through the mail-bags. We must again impress upon our correspondents the necessity of enclosing specimens sent by mail in something that will resist a good deal of pressure—stiff pasteboard or tin boxes, for instance—else they are apt to reach us in a perfectly unrecognizable condition. "J. J.'s" specimens, however, are old friends, whom we should think it unpardonable not to recognize; we speak advisedly, they are *our friends*, but deadly foes to plant-lice. They belong to the family of Ladybirds (Ladybugs some people call them—a combination of names that ought to be abhorrent to everyone possessing a spark of gallantry), and are of a deep shining black colour, with a roundish blood-red spot on each wing-cover, whence they derive their name, the Twice-wounded Lady-bird (*Chilocorus bivulnerus*, Muls). These little insects, as well as all the other Lady-birds, should never be killed, for we owe to them in a great measure that all vegetation is not destroyed by plant-lice.

THE GRAPE-VINE FLEA BEETLE (*Graptodera chalybea*).—Now is the time for grape-growers to be on the look-out for this very destructive insect; it is quite abundant in some localities at the present moment. The best remedies for it are hand-picking, which we consider the most effectual, and syringing with strong soap-suds. For a description and figure of the insect, see the CANADA FARMER for 1867, vol. iv, page 327.

CURRANT-BUSH INSECTS.—The numerous foes of the currant-bush are now hard at work at leaf and stem. We have already found nearly full-grown larvæ of the Saw-fly, and small specimens of those of the well-known Moth. A highly recommended remedy for these insects is a mixture of White Hellebore and Alum in water; it is affirmed to be effectual by many persons in Toronto upon whose statements we can rely. We are about to give the receipt a thorough trial ourselves, and shall acquaint our readers with the result. The larva of the moth that bores into the stalks is now causing much injury also; all dead or dying stalks should be cut off and burnt at once.

FLEAS IN SOUTHERN INDIA.—Observing in the "Zoologist" a note remarking on the decrease of fleas of late years, it may interest the writer and others to hear that in this neighborhood, on the contrary, they were never, to my knowledge, so numerous as at the period referred to; I remember to have heard great complaints. I am not aware whether fleas breed and multiply on our shores, though in the South of India I have found them among the sand-hillocks skirting the sea in countless numbers; for instance, on one occasion, when passing a few days (in the year 1832) at a bungalow on the shores of the Gulf of Manar, I could not stroll on the beach of an evening without being covered with fleas from head to foot, so that my white dress was completely dotted and spotted with them. Fortunately, being of a sluggish kind, they could be brushed off by hundreds; however, I was eventually driven back to my head-quarters at Ramnad, finding the flea-plague even worse than the plague of mosquitoes, on the scorching sandy plains around the fort.—*Henry Hadfield; Ventnor, Isle of White, in the Zoologist.*

The Apiary.

Dividing Swarms.

No certain rule can be given as to the right time for dividing colonies, as seasons are so different and localities so unlike with respect to the putting out of blossoms. As a rule, I find that when fruit blossoms early, and good weather prevails during its blossoming, it is safe to expect early swarms. No new colonies can safely be made before drones appear, as on them depends the impregnation of the young queens.

It is always best to choose a time when the nights are warm, or the young brood may suffer after so much surplus population is taken from the hive.

Those who have used moveable frame hives for any length of time will have become familiar with various ways in which colonies may be divided; such need no aid in the matter, but a word or two of caution may be "in order." Never expect to benefit a colony that is not doing well by making two of it; unless a hive is very strong in numbers and in all ways prospering, do not divide it. Generally, such colonies may best be made vigorous by taking away their queen and replacing her by a young one.

Never divide when honey is not very abundant.

In making the division, whatever way you practise, be sure to have the main part of the worker force of the colony with the queen, leaving the hatching brood with few old bees in the old hive. To do this easiest, it is well to have the queen in a new hive on the old stand, while the old one is removed some distance away.

It always pays to rear queen cells eight or ten days in advance of swarming time, so as to give the part of the colony left queenless a queen cell nearly mature, thus saving them much time.

If the greatest yield of surplus honey is the object, it may best be secured by making no more than one new colony from each one in a season; where little fall pasturage is found, it is generally best to be contented with securing one new colony from two old ones, thus:

Take three frames of comb, containing brood and stores, from a good colony, replacing them by empty frames; put them in an empty hive and set it where the one from which the frames were taken stood; then move another strong colony a rod away, and put the one from which you took the frames where that one stood. In the new hive you have brood and stores and a good colony of bees; in the one from which you took the frames, there is still left brood and stores, and by setting it where a good hive was, you secure to it plenty of bees; one of these hives will contain a queen, it matters not which, for both are alike well provided with materials for producing another. The hive that you move a rod away will lose nearly as many bees as if it swarmed, but it keeps its queen and all of its brood, and will soon be strong again, much more so than if it had lost its queen as in natural swarming.

There are many whose bees are still in box hives, who wish to transfer them with the least possible loss to moveable comb hives. Such will find swarming season the best time to do it. The matter is very simple. In the middle of a warm, pleasant day smoke the hive that you wish to drive, in order to alarm the bees and induce them to fill their honey sacs; wait five or ten minutes, and then take the hive and carry it a few yards away; turn it over and put on top of it a box or cap as near the same size as possible. With sticks now drum smartly on the lone hive, making a continued jar, and the bees will mount rapidly into the upper box, and soon be found banging to it like a swarm. Take it off, then, carefully, and set in the shade. Carry the hive from which you drove the bees, to a location two or three yards behind where it stood before; it will keep bees enough to rear a queen and do well. Put your new moveable comb hive on the old stand, spread a sheet before it, and then empty the bees from the box upon the sheet, and they will run up into the hive, and go to work there like a swarm. It is well, if you have any good pieces of comb, to fasten them in the frames, as it gives the bees what all like—"a start in life." If you wish to transfer combs and all from the old hive, it can best be done just three weeks after the swarm is thus taken from it. At that time there will be little or no brood in the combs, and they can be easily handled; they will have a young queen, but she will not have deposited many eggs. Full directions for transferring combs are given in any standard work on bee-keeping. The operation is very simple.—*Mrs. E. S. Tupper.*

The Household.

The Household Lamp.

When suns decline, and crickets sing,
And wandering mists from seaward roam,
When nights no heavenly beacons bring,
Then brightest shines the star of home!

When the brown brooks, with music low,
Watch summers die and autumns come,
When stately golden rods must bow,
What cheer is in that light of home!

When winter strips the shuddering trees,
And chills the wavelet's wanton foam,
When in the world's cold grasp we freeze,
How blest is then that star of home!

Atlantic Monthly.

Emergencies.

PRESENCE of mind, under sudden alarm, is a species of moral courage that is rarer than might at first be supposed, and it requires the test of actual danger, or some stirring emergency to establish any one's claim to the possession of this valuable quality. Many persons are very brave or very wise when danger and embarrassment are at a distance, who entirely lose their self-possession when the time of trial comes unexpectedly upon them. This common deficiency of character is humorously described by Mr. Dickens in the "Pickwick Papers." Who does not remember the scene in which Mr. Pickwick, whilst enjoying with a merry company the exhilirating exercise of sliding on the ice, suddenly falls through with a crash and disappears? The gentlemen of the party, we are told, turned pale; the ladies fainted; Mr. Snodgrass and Mr. Winkle grasped each other by the hand, and gazed at the spot where their leader had gone down; while Mr. Tupman started off at the top of his speed across the country, calling "fire!" and it was not until the features and spectacles, followed by the shoulders of the old gentleman, emerged from the surface of the treacherous ice, and it was also announced that the pond was nowhere more than five feet deep, that the major part of the company recovered their senses, and were ready to perform prodigies of valor in the rescue. We have heard also of the lady whose first thought on learning that her house was on fire, was to save her best china, which she forthwith hastily collected and pitched out of the window. The actual experience or recollection of most readers will, doubtless, suggest similar instances of the want of presence of mind.

There are many cases, however, where the embarrassment arises less from a deficiency of this rare quality than from ignorance of what is best to be done under the circumstances. When people are left to their own resources, and neighbourly help is not always accessible, it is especially important that they should be prepared, by a little simple knowledge as well as common sense, for emergencies that may happen at any time. We remember seeing, many years ago in England, a very useful printed sheet, headed "Hints for Emergencies," in which were given plain and sensible directions for the course of action to be immediately adopted in the event of a variety of accidents in which any one might be suddenly called upon to render aid, such as fire, drowning, poisoning, &c., &c. We do not know whether this useful guide could be obtained now; but any one might, with a little pains, put together a similar compendium of useful hints for his own use, and the time might come when, if memory failed at the moment of need, a reference to such a written memorandum might be of immense value. To aid those of our readers especially whose lot may be cast in the back settlements of the country, we propose occasionally to give a few simple instructions as to the best course of action in the more common emergencies. We will begin with just one or two accidents to the person.

Not long since we gave an extract from one of our exchanges, under the heading "*How to act when the clothes take fire.*" We would again refer to the directions there given for guidance in this emergency, merely reminding the reader that the chief things to do promptly are; to throw over the flames, so as to smother them out, a rug, blanket, or anything of the kind that most readily comes to hand, and to lay the person whose clothes are on fire flat on the ground. When a burn is superficial and affects only a small space, immersion of the part in cold water will generally give great relief. Dredging flour over the burnt part, so as completely to exclude the air, is also one of the best applications in the first instance, and will sometimes be all that is necessary.

Next, let us take the case of *Fainting.* A person suddenly turns pale, and falls, losing his consciousness. Friends are alarmed, and sometimes not knowing what else to do, will raise the person into a sitting posture. Now, this is just about the worst thing that could be done. The pallor of the face should teach us that the heart is acting feebly, and does not send the blood into the head in the ordinary manner. Every facility should be given to let the blood flow towards the brain, and for this purpose a horizontal position, with the head even lower than the rest of the body, is the most desirable. Fresh air is a most important auxiliary; cold water, or even occasionally a little brandy, may be serviceable; but the horizontal position, or, in plain words, lying down, will generally bring about a speedy recovery.

Not to extend this article to a tedious length, we will notice at present only one case more, namely, the accidental taking of poison. In these cases it is not always easy or possible to ascertain what special poison has been taken. The only safe rule, then, applicable to all cases, is the instant administration of some efficient emetic. The best, such as sulphate of zinc or ipecacuanha, may not be at hand; though it is well, by-the-by, for persons living in lonely situations to have a few common remedies in the house. If either of these is procurable, then the proper dose of sulphate of is zinc about a scruple, or half a small teaspoonful, given in lukewarm water. The dose of powdered ipecacuanha is nearly double that quantity—that is, half a drachm, or nearly a teaspoonful. If the first dose of either does not answer the desired end in about a quarter of an hour, it should be repeated. When neither of these remedies is at hand, common table mustard may be used, and is a tolerably good emetic. From a teaspoonful to a tablespoonful, given in warm water, is the proper quantity. In addition to this, drinking freely of milk, or the white of an egg, is in the case of certain poisons a most valuable antidote, and in others often useful.

Perhaps the most common poisons that are taken accidentally are arsenic, corrosive sublimate, and oxalic acid. If it can be ascertained that any one of these has been swallowed, the appropriate antidote should be administered as speedily as possible. For arsenic the best antidote is sesquioxide of iron—a large teaspoonful for a dose. White of egg and milk are also useful. For corrosive sublimate white of egg is the very best corrective; for the poisonous salt unites with the albumen and forms an insoluble compound. For oxalic acid, lime is the proper antidote. This is best administered in the form of chalk.

These few hints may be useful, and worth remembering. In some future article we hope to notice and give directions for the proper course of proceeding in some other emergencies.

WHAT A YOUNG WOMAN DID.—I have an acquaintance in the middle class of society, the income of whose business was a comfortable support for his wife and three daughters. The eldest of the girls found much of her time unoccupied, except with unproductive fancy work, and she said to her mother: "Why should we all be dependent upon father for support? If he should die how helpless we should be. And even if he lives, and is able to work for a long time to come, we might relieve him from much care and anxiety by our exertions, and we might greatly increase our own opportunities for improvement." She followed out her ideas by fitting herself to be a book-keeper. Not satisfied with a small salary, she diligently applied her spare hours to acquiring a thorough knowledge of French and Spanish; and having an object in view, she learned rapidly. When she was able to write commercial letters in these languages, she soon commanded a salary of fifteen hundred dollars. Every morning she walked into the city with her father, where they parted to go to their separate places of business and met to return home in the afternoon. Most fashionable women had probably taken up as much time spending money during the day, as she had spent in earning it. Her example stimulated a younger sister, whom she aided in the development of her artistic talent, till she became a teacher of drawing in a large educational establishment.—*Ex.*

Useful Receipts.

A BAKED APPLE PUDDING.—Boil six apples well; take out the cores, put in half a pint of milk thickened with three eggs, a little lemon-peel, and sugar to the taste; put puff-paste round the dish, bake the pudding in a slow oven, grate sugar over it, and serve it hot.

CAROLINA WAY OF BOILING RICE.—Pick the rice carefully, and wash it through two or three cold waters till it is quite clean. Then (having drained off all the water through a colander) put the rice into a pot of boiling water, with a very little salt, allowing as much as a quart of water to half a pint of rice; boil it twenty minutes or more. Then pour off the water, draining the rice as dry as possible. Lastly, set it on hot coals with the lid off, that the steam may not condense upon it and render the rice watery. Keep it dry thus for a quarter of an hour. Put it into a deep dish, and loosen and toss it up from the bottom with two forks, one in each hand, so that the grains may appear to stand alone.

ARROW-ROOT PUDDING.—Simmer a pint of milk with a few whole allspice, coriander-seed, and half a stick of cinnamon for ten minutes or a quarter of an hour; then sweeten it with sugar, and strain it through a hair-sieve into a basin to one ounce and a half of arrow-root (about a tablespoonful and a half) previously mixed with a little cold milk, stirring it all the time. When cold, or as soon as the scalding heat is gone, add three large or four small eggs, well beaten, and stir well until the whole is perfectly blended. It may then be boiled in a well-buttered mould or basin, or baked in a dish with a puff-paste crust round the edge, and grated nutmeg on the top. From half to three-quarters of an hour will be sufficient to boil or bake it. When boiled, serve it with sauce. The flavour of the pudding may be occasionally varied by using a few blanched and finely-pounded or chopped sweet and bitter almonds—about one ounce of sweet, and half an ounce of bitter—or with orange-flower water, or vanilla.

PICKLED CABBAGE.—A correspondent of the *Country Gentleman* says: "In response to the enquiry, 'how to pickle cabbage?' I send the following, which my folks have tried several years, and I know to be good, and is liked by those who have eaten it. It keeps well a year, and how much longer it would keep I am unable to say. If one is not over nice in regard to the form in which it is served, I think it will suit the palate of any who are fond of the like pickle. Take any quantity of well-formed cabbage-heads, and thick-meated squash, or bell-peppers, and chop them fine and mix. Use about one-third pepper, and two-thirds or more of cabbage after being chopped; for each gallon take one heaping teaspoonful of ground cloves, about half the quantity of ground cinnamon, half a tea cupful of whole mustard seeds, and two tablespoonfuls of fine salt; mix thoroughly and place it in a stone jar, and pour over it scalding hot cider vinegar; cover and set in the store room, where it will keep cool and not freeze. It will answer to use after 24 hours. Small green tomatoes or other vegetables may be added, if desired, and pickled whole. One who does not like to be at the trouble of stuffing peppers will here find an excellent substitute. The vinegar should not rise above the cabbage, only well saturate the mass."

Poetry.

The Grass

The grass, the grass, the beautiful grass,
That brightens this land of ours,
Oh, why do we rudely let it pass,
And only praise the flowers?
The blossoms of spring small joys would bring,
And the summer-bloom look sad,
Were the earth not green, and the distant scene
In its emerald robe not clad.

Then sing the grass, the beautiful grass,
That brightens this land of ours;
For there is not a binde by nature made
Less perfect than the flowers.

The grass, the grass, the feathery grass,
That waves in the summer wind,
That stays when the flowers all fade and pass
Like a dear old friend, behind;
That clothes the hills and the valley dills,
When the trees are stripped and bare;
Oh, the land would be like a wintry sea,
Did the grass not linger there.

Then sing the grass, the bonny green grass,
That to all such a charm can lend;
For 'tis stanneh and true the whole year through,
And to all a faithful friend.

The grass, the grass, the bountiful grass,
Oh, well may the gift endure,
That never was meant for creed or class,
But grows for both rich and poor.
Long may the land be rich and grand
Where the emerald turf is spread;
May the bright green grass, when from earth we pass,
Lie lightly o'er each head.

Then sing the grass, the bountiful grass,
That stays like a dear old friend;
For whatever our fate, it kindly waits,
And it serves us to the end.

Ex.

Miscellaneous.

Respectability of Farming.

THE cities are full of young men—many of them from the country—who are out of employment and are glad to work for enough to pay their board. They could save enough money by working on a farm for a few years to buy one for themselves. But they think it more respectable to sell pins and measure tape. For my own part, I respect any man who is striving to make an honest living by any kind of manual or mental labour. But I give the preference to agriculture, because it is in itself the main foundation of our national prosperity, and because it calls into exercise the best faculties of our nature. A clergyman can be a farmer without soiling his cloth. As I was coming home to-day a city man asked me to give him a ride. "Do you live on your farm now?" he asked, "and how do you like it?" "Pretty well," I replied. After a few remarks as to the scarcity of water, what good sleighing we had had, and how warm it was to-day, &c., he remarked, "I wonder why you would not be a good man to keep tavern." It seems that he and a few others had built a tavern somewhere, and wanted some one to take charge of it. "If you had a few hundred dollars to buy furniture," he said, "you would get rich out of it." I told him I did not know enough to keep a hotel, and that I liked farming. "But," said he, "you could have a farm there, though I have known a good many farmers who went to keeping tavern that soon run the thing into the ground!"

Now, all this was intended to be very complimentary. In his eyes a tavern-keeper was considerable of a man, and in return for giving him a ride, he wished me to go home with the comforting assurance that there was one man at least who thought I was fitted for something better than a farmer. It is to be feared that I did not thank him with that degree of warmth such kind intentions deserved. He will doubtless conclude that "these farmers are a boorish set; they don't know enough to be polite."—*Harris's Walks and Talks.*

FEMALE FARMERS.—When a young lady offers to hem a cambric handkerchief for a rich bachelor, she means to sow in order that she may reap.

☞ An ugly young lady is always anxious to marry, and young gentlemen are seldom anxious to marry her. This is a resultant of two mechanical powers—the inclined plain and leave her.

ALL THE SAME.—An Irishman had to give the password at the battle of Fontenoy at the time the great Saxe was marshal. "The pass-word is *Saxe;* now don't forget it, Pat," says the colonel. "Saxe! faith, and I won't; wasn't my father a miller?" "Who goes there?" said the sentinel, after he had arrived at the pass. Pat whispered confidentially, "*Baas*, your honor."

J. H. THOMAS'

FIRST PRIZE BEE HIVES!

THE FIRST PRIZE has been awarded these Hives at the Provincial Fairs, and many County Fairs, for the last four years. They also obtained the first prize at the Michigan State Fair, held at Detroit last year. In fact they have always been awarded the first prize wherever they have been entered. During the last four years they have acquired a reputation unequalled by any hive heretofore offered to the public. They are now manufactured by steam-power, which will enable me to supply the increasing demand at the following rates, which include a right to make and use both double and single bearded Hives:

Single-boarded Hive	$5.00
Single-boarded Observing Hive—Glass in two sides	7.00
Double-boarded Hive	6.00
Double-boarded Observing Hive—Glass in one side	7.00
Single-boarded Observing Hive—Glass in one side	6.00
Double-boarded Observing Hive—Glass in two sides	8.00

All persons purchasing a Hive at the above rates, (which always includes the right to make), and preferring to order Hives of me, rather than make, will be supplied at the following prices:—D. B. $3.50; S. B. $2.50; or if ordered in lots of three to one address, D. B. $3.25; S. B. $2.25; in lots of six, D. B. $3; S. B. $2. Hives sent safely as freight by rail to any part of Canada. Three hives to one address for the same freight as one hive. Bee-keepers would do well to form clubs and order three or more hives sent to one address, and thereby save freight.

ITALIAN QUEENS AND BEES!

Having secured the services of H. M. Thomas, one of the best practical apiarians in Canada, to assist me in breeding Italian queens, I shall be able to furnish any number at the proper season, bred from the very latest importations. PRICE $5 each. I will also furnish a limited number of Italian Stocks in the fall, at the following prices:—In the D.B. hive, $20; in the S.B. hive, $15; sent by express at the expense and risk of purchaser. The Canadian Bee-Keeper's Guide sent to any address post-paid for 25 cents, five copies for $1. The trade supplied at a liberal discount.

Persons desirous of purchasing territorial rights for my Hives, would do well to apply at once, as I will sell for the next two months, Townships at from $20 to $30, and Counties from $50 to $150.

J. H. THOMAS,
Brooklin, Ontario.

N.B.—Parties residing in the Counties of Carleton, Russell, Ottawa, Pontiac, Renfrew, Lanark, Leeds, Dundas, Stormont, Glengarry and Prescott, and desiring to purchase my hives, must in all cases address their orders to JOHN HENDERSON,
New Edinburgh, Ont.

DAIRY necessaries of every description always on hand, particularly **Pure Annatto**, an article in much request among dairymen.

No Duty on Annatto purchased in the United States.

☞ Special attention given to Canadian orders. v4-19-tf

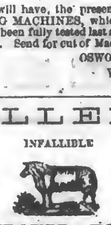
TO FLAX GROWERS.

THE undersigned will have, the present season, a supply of FLAX-PULLING MACHINES, which we can guarantee to do good work, having been fully tested last season. New improvements added this year. Send for cut of Machine and Price List.

OSWOLD & PATERSON,
Woodstock Iron Works.
1st May, 1868. v5-9-6t.

MILLER'S

INFALLIBLE



TICK DESTROYER FOR SHEEP!

DESTROYS the TICKS; cleanses the skin; strengthens and promotes the growth of the wool, and improves the condition of the animal.

It is put up in boxes at 35c., 70c., and $1, with full directions on each package. A 35c. box will clean twenty sheep.

HUGH MILLER & Co.,
167 King Street East. Medical Hall, Toronto.
v4-14-tf

FARMERS AND GARDENERS

LOOK OUT FOR YOUR CURRANT BUSHES &C.

THE CHINESE

GARDEN POWDER!

DESTROYS ALL KINDS OF

Insects, Grubs, and Caterpillars,

On Currant Bushes, Plants and Shrubs. You will save money, labour and disappointment.

Prepared only by

HUGH MILLER & CO.,
Medical Hall,
v5-11-2t 167 King Street East, Toronto.

GEO. A. DEITZ,

The Great Seed Wheat Grower,

CHAMBERSBURG, Pa., sends free a Descriptive List of the best Seed Wheats in the world. v5-11-6t

FOR SALE,

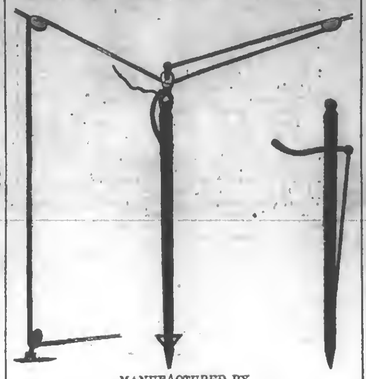
THREE yearling **Durham Bulls**—two red and one roan. Apply to

GEO. MILLER,
v5-11-2t* Markham.

M. L. ROBERTS'

PATENT

HAY ELEVATOR



MANUFACTURED BY

T. WRONG & CO.,

No. 70 BAY STREET,

TORONTO.

PRICE $10, WITH PULLEYS AND ROPE.

☞ AGENTS WANTED. v5-12-1t.

Markets.

Toronto Markets.

"CANADA FARMER" Office, June 11th, 1868.

The market has recovered from the decline mentioned in our last review, and prices are now advancing slowly, and have reached a point considerably higher than our quotations of last number.

Flour—The market has improved during the week, and a considerable advance over last quotations has been established. No. 1 Super now sells without much difficulty at $6. Several lots changed hands at that price yesterday and to-day; in the higher grades there has been nothing doing, and prices are entirely nominal.

Oatmeal—There has been nothing doing in this article during the week. Quotations are nominal.

Cornmeal—The market is dull and nominal. Nothing doing.

Wheat—In sympathy with markets east and west, the market here has improved. An advance of from 5c to 7c over last week's quotation has been established. Fall is now in fair demand at from $1 45 to $1 50. Several car lots have changed hands at these prices. Spring wheat has also advanced; lots have been bought at from $1 40 to $1 42, these prices ruling to-day on Change. The demand has considerably improved, but there is still not much doing.

Oats—The market is dull; several sales of car lots were made during the week at 52c.

Barley—The demand has become very light. For a few car loads $1 05 would still be paid.

Peas—The market has been very dull during the week. No sales were reported; quotations are, therefore, nominal.

Pork—The market is dull and only a retail trade doing; nominally unchanged; worth $23.

Bacon—Slow of sale at from 10c to 11c for Cumberland.

Cut Meats—Trade is confined to retail lots. We quote hams—smoked, 12c to 12½c; canvassed, 13c.

Butter—The market has been steadily declining, and prices may now be quoted at from 12c to 13c. The recent fine weather is having a depressing effect upon the market, increasing the supplies largely and bringing down prices.

Eggs—Market firm and higher. There is a shipping demand for New York. Worth from 10c to 11c for shipping.

Cheese—Very little in the market. Only a retail trade doing—worth about 11c.

Lard—Nominal, none in the market.

Potatoes—There is a fair supply. The current rates are 65c to 70c per bush by the load, and 90 to $1 per bush by the bag.

Apples—The market is firm; choice samples bring as high as $3. Dried, dull; worth $1 25 to $1 50.

Plaster—The market is fairly active; selling prices $1 05 to $1 10 on the wharf.

Water Lime—Selling at $1 60.

Hay—As high as $22 was paid for a few loads to-day; prices ranged from $11 to $21.

Straw—Prices range from $12 to $16.

New York Markets, June 10.—*Flour*—Dull; receipts 5,630 bbls; sales 6,900 brls at $7 60 to $8 10 for super state and western; $8 50 to $9 20 for common to choice extra state; $8 25 to $10 for common to choice extra western. *Wheat*—Quiet and weak; receipts, 96,000 bushels; sales 15,000 bushels at $2 19 for No. 2 spring; and $2 27 for No. 1 do. *Rye* quiet; receipts, 750 bushels; sales 400 bushels Southern at $2 02. *Corn* lower; receipts, 100,000 bushels; sales 70,000 bushels at $1 08½ to $1 09 for new mixed Western afloat; and $1 16 for white Western. *Barley* quiet. *Oats* easier; receipts, 35,000 bushels; sales 47,000 bushels at 86c for western afloat. *Pork* dull and lower at $28 25 to $28 37 for mess $27 62 for old do. *Lard* steady and quiet at 18 and 11¾c to 19¼c for kettle rendered.

THE CANADA FARMER is printed and published on the 1st and 15th of every month, by the GLOBE PRINTING COMPANY, at their Printing House, 25 and 28 King Street East, Toronto, Ontario, where all communications for the paper must be addressed.

CLUBS will be furnished at the following rates:—

TEN COPIES for..... NINE DOLLARS.
TWENTY COPIES for..... SIXTEEN DOLLARS.
FORTY COPIES for..... THIRTY DOLLARS.
ONE HUNDRED COPIES for..... SEVENTY DOLLARS.

To Agricultural Societies ordering more than 125 copies, THE FARMER will be sent at SIXTY CENTS.

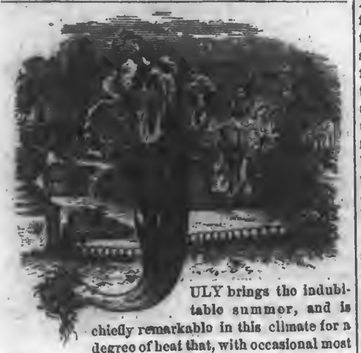
THE CANADA FARMER presents a first-class medium for agricultural advertisements. Terms of advertising, 20 cents per line space. Twelve lines' space equals one inch. No advertisement taken for less than ten lines' space.

Communications on Agricultural subjects are invited, addressed to "*The Editor of the Canada Farmer*," and all orders for the paper are to be sent to

GEORGE BROWN,
Managing Director.

VOL. V. No. 13. TORONTO, CANADA, JULY 1, 1868. POSTAGE FREE.

The Month.



ULY brings the indubitable summer, and is chiefly remarkable in this climate for a degree of heat that, with occasional most welcome relentings, keeps us almost constantly in a sweltering condition, and makes our anticipations and memories of the month rather painful than otherwise. We hail June, but dread July. "Ike Marvel" says: "I picture July as a stout woman perspiring fearfully; yet she wears a cheery, honest face, and if she have none of the bridal freshness of May and June, she wears the honours of maternity, and leads in a great brood of flowers and fruits in her train."

The mean temperatures for this month at various leading points in Canada are as follows:—

Stratford	66° 64'
Hamilton	72° 47'
Barrie	71° 88'
Toronto	70° 40'
Belleville	71° 87'
Montreal	69° 35'
Quebec	71° 00'
St. John, N.B.	61° 75'
Halifax	61° 00'

The above table shows nearly four degrees difference between Toronto and Stratford, makes Toronto and Montreal nearly alike, and, strange to say, gives Quebec a slight superiority in point of heat over both Toronto and Montreal.

We are still having a splendid season. The June frost put in a very feeble appearance, just enough to be identified, but doing no mischief. Copious rains have fallen from time to time. Nature seldom wears robes of such gorgeous green as the present summer. It has been a most favourable time for transplanting, and nurserymen, who are usually treated to many unjust execrations on account of dead trees, will this year have immunity from censure. Evergreens never wore a richer or more varied foliage than now. Grain and grass are most luxuriant. The face of the earth is radiant with smiles, and bewitching with beauty. There is promise of abundance of fruit, and crop prospects generally are all that could be desired. Will farmers find any cause for grumbling this year? As a class, they are so given to complaining, and so fearful it should be thought they are doing well, that we have our misgivings lest even the present season may not escape without some fault being found with it. The grain stalks will be so heavy that there will be lodging, the midge will commit a world of havoc, some of the best trees in the orchard will break down under the load of fruit, produce will be so plentiful that the prices will be low. Yes, not a doubt of it, but in the song of the year there will be a low, bass (base?) note of dissatisfaction with something or other. But if ever heaven rebuked this disposition surely it is now.

Thorough cultivation of the soil, unrelenting slaughter of weeds, turnip hoeing, hay-making, and wheat harvesting are the chief labours of the month. All crops that admit of it are greatly benefited by frequent stirring of the soil about them. July is a most favorable time for the extirpation of weeds. Only scratch them out of the ground, and the scorching sun will do for them very quickly. In a damp, cool time it often seems of but little use to hoe among weeds, they take root again so quickly, but the July heat finishes them in no time. Even the Canada thistle will "cave in" if hoed up or mowed down in July. The latter process is highly recommended by many farmers. It is especially likely to be effectual if rain come shortly after the mowing, as the wet filling the stalks and settling into the roots, induces quick decay. Almost the only bit of advice necessary about haying is to be sure and cut at the proper time; not too soon, or the fodder will be deficient in substance and nutritious properties; nor too late, or it will be tough, woody, and sapless. Grass ought to be mowed between blossoming and seeding. Very much the same advice may be given about harvesting wheat. The *Illustrated Annual Register of Rural Affairs* says:—"Cut wheat a week before full ripe. The grain will weigh more and be better. The straw will be brighter and richer." Early cutting of grass not only improves the hay, but secures a better after-growth for a second mowing, or for pasturage.

A word about the turnips. Early in July is the time to secure a good plant, and attend to proper thinning in the rows. Re-sow if there be extensive failure, through fault in the seed, or depredations of the fly. Gaps in the rows may be filled up either by transplanting or sowing again. When too late for Swedes, Yellow Aberdeens and White Globes may be sown. One great essential to success in turnip-growing is to get the plants thinned at the proper time. If left too long it is almost impossible to retrieve the error. A sharp hoe, about eight inches wide in the blade, is the tool to thin with, and a skilful hand will go over the ground very fast. This well done, and all danger [illegible] fly past, they will grow very fast quickly [illegible] the ground, and form bulbs.

Though [illegible] end of June is the usual time for sowing buckwheat, it does well most seasons if sown early in July. We recommended this crop last month for cakes and green manure, but forgot to speak of its value to bee-keepers. Buckwheat honey is not a choice table article, but it is good enough winter feed for the bees themselves, and it is easy to rob them of their white clover stores, and compel them to stock up again from buckwheat blossoms. The great drawback to bee-keeping in this country is the want of late summer and early autumn forage. This is removed in localities where buckwheat is largely grown.

Happy is the farmer who has green corn, vetches, or other soiling crops, wherewith to eke out the pasturage so apt to fail under the fervid heats of July. His milk pails shall still be full to overflowing, his butter and cheese rich as in June, his young stock shall grow without check, and his teams continue fat, sleek, and strong to labour. He that has no patch of green fodder for a time of need in July, may yet have one for a similar time in September. A rich bit of ground near the barn should be chosen for this purpose, and sown forthwith.

Orchards will be grateful for a stirring of the soil this month. Over-production of fruit should also be guarded against, and care taken that the trees are not broken down through being over-loaded. Now is the time for thumb-pruning of young fruit-trees, and thereby giving beauty of shape, vigour and fruitfulness to them. Budding may be done so soon as the terminal buds are well formed. Grape vines may be layered this month, and well-rooted plants obtained by winter. The duties of the garden in July are more than can be well enumerated. In fact their name is "legion" at all times when work is practicable. Extermination of weeds is the chief thing to be done this month. This must be thoroughly accomplished year by year. "Eternal vigilance is the price of" a garden, as well as "the price of liberty."

July is the Apiarian's harvest. Now, if at all, the surplus honey boxes are to be filled, and such arrangements made as will maintain stocks in full number and strength. Put on boxes forthwith, if they have not yet been supplied. Prevent late swarming, or unite two or three to make vigorous colonies. There is nothing more conducive to successful bee-keeping than to see to it that colonies are strong. Weak stocks are liable to many evils that never trouble strong ones. Some bee-keepers imagine that strong stocks consume far more honey in proportion than weak ones, and are therefore harder to winter. This, however, is a mistake, as is every other argument in favour of weak rather than strong colonies. The value of an apiary is to be estimated, not by the number, but by the weight of the hives composing it.

The Field.

"Eight Dollars an Acre."

A WRITER in the June number of the *American Journal of Horticulture*,—a periodical, by the way, of great excellence,—mentions the case of a Vermonter who, reporting his management of his farm of 125 acres, finds a balance for profit of $732.68 on the year's operations, and seems quite contented in view of the result, complacently remarking: "This, I think, is better than money at six per cent., and answers the question as to whether farming is profitable." Allowing for the woodland, this is about eight dollars an acre. This case is used to point a contrast between the said Vermont farmer and the New Jersey market gardeners, one of whom, a fair average specimen, is reported to have made $711.50 from less than four acres of extremely light land, or within a trifle of the gain upon thirty times the same number of acres devoted to grass and grain, in the case first instanced. Of course, near access to a market like New York or Philadelphia goes far to explain the difference, for the four acres of "truck" side by side with the farm crops on some White Mountain slope, would have been worth little more than the average profit per acre of the farm. Our object in referring to the Vermont example is to make it the occasion of putting three questions, which we beg our readers attentively and seriously to ponder.

I. How many farmers know what they make per acre annually? In other words, how many farmers are there who keep a set of accounts? We fear there are very few who have data on which to frame an answer to the enquiry, "what are your profits per acre?" Beyond vague general impressions on the subject scarcely any can go. When the crops are short they have an indefinite idea that they are not doing much, and when there is an abundant harvest they have a similarly indefinite idea that they are not doing so very badly; but, generally speaking, farmers "shoot in the dark," and "go it blind." Now, surely, this is discreditable and undesirable. Why should a large farm be carried on in a way that would be disgraceful in connection with a little huckster's business? No commercial concern could be reasonably expected to prosper, if carried on after the fashion on which too many farms are conducted. Confusion and loss would be the sure result. We conjure all and sundry to keep note of expenditure and income, so as to know how much per acre they are making year by year.

2. Is there good reason to think that farmers generally, take one year with another, clear "eight dollars per acre?" We apprehend that a negative reply must be given to this question. There are, doubtless, those who are making far more than the figure above mentioned; assuredly there are those who make much less; while we fear the majority cannot flatter themselves that they reach the average named. We know a better-than-ordinary farmer, cultivating over a hundred acres, who stoutly maintains that, taking one year with another, he is not so well off as a book-keeper or salesman who has a salary of six hundred dollars a year, and who would be glad to sell his farm, and take a situation of the kind just named. We have no objection to be contradicted, and to stand corrected by "stubborn facts,"—indeed, we should rather like it than otherwise—but our present conviction is, that it is by no means the majority of our farmers who make a yearly profit of "eight dollars an acre."

3. We have yet another enquiry to put, and it is this, ought a nineteenth century farmer to be contented to make *only* "eight dollars an acre?" We answer, decidedly, *very decidedly*, not That sum implies less than twenty bushels of wheat per acre; less than three hundred bushels of turnips per acre; not much more than a ton of hay per acre. A good system of rotation, a well-balanced quantity of stock and produce, liberal manuring, good tillage, a wise mixed husbandry, ought to accomplish more than this. Capital wisely invested, and labour well directed, should assuredly yield a better return. Such a balance sheet can hardly be said to exhibit successful farming. It does not satisfactorily meet the question, "Is farming profitable?" Contentment is a virtue only when we are doing our best. Let every effort be made to bring out the innate capabilities of the soil, and the recompense is certain. To till a smaller quantity of land, and do it better, would be the part of wisdom with many. Our counsel to every Canadian farmer is this: Keep exact accounts, work up your land to the highest point of fertility practicable, and set for yourself a higher mark than "Eight dollars an acre."

Clover versus Fallow.

To the Editor of THE CANADA FARMER:

SIR,—More than four months having passed away since you published my remarks on the subject of the Canada Thistle, and of an inexpensive way of getting rid of them, I had concluded that the thistle-growers of Canada saw no reason to trouble themselves further about it, but your number for May 15th has agreeably disappointed me. My outspoken, but friendly opponent, Peter Shisler, has done his best, in reviewing my letter, published in the first two numbers of this year's issue, to support a plan which I think thoroughly detrimental to the farmers' interest, and as such seriously affecting the welfare of the whole Province. We, as a family, are constantly in the habit of reading your paper, which has become quite a household necessity, and sometimes there is a little grumbling that the *two weeks* seem a long time, and sometimes I have heard remarks as follows: "Well, now, that is well worth knowing," "Yes, that is worth the year's subscription." But there are articles now and then make their appearance which cannot fail to puzzle, the opinions expressed being nearly as opposite as the poles. Last year a writer appeared on the stage, recommending his *eighty* bushels of potatoes to the acre, for seed, and this curiosity excited no reply. In your April number you quote from a States paper a plan requiring (as I understand it) about eight bushels an acre, which is a considerable difference. These extremes, while they puzzle, set men thinking, and from thinking to experimenting for themselves, and then they are on the right track, and will not fall in the end to benefit themselves. The question as to which is the best mode of subjugating the thistle (as subjugated they must be) is a subject fit for the philanthropist, as well as the philosopher, and whoever shall accomplish the task will be entitled to the grateful acknowledgments of the people of the Province. In submitting this for your consideration, (as a rejoinder to Peter Shisler's last letter, published in the CANADA FARMER, 15th May) you will please remember that my remarks applied to the two writers, (and the only two of the year) namely, the steam-plough advocate and to P. S. The first has remained silent, and the second has come out square on the mystic fallow as the great remedy for the great evil.

I quite agree with the substance of the first paragraph of the letter of P. S., namely, "The theory or practice that cannot stand a scrutinizing investigation should go down." He also informs us that "too many false systems and humbugs have been imposed on the farmer, causing him to spend time and money to no purpose," and yet he only mentions one, namely, "cutting (thistles) *in the moon*." In this paragraph P. S. has dipped his pen in vinegar, and approved of a mild mixture of *invective*, in defence of the misguided and abused farmer.

In the second place, he becomes jubilant, if not eloquent, in declaring "that my arguments show most conclusively, and ought to convince the most sceptical, that his method is the right one." I have heard that Irishmen are allowed to speak three times, Scotchmen twice, but an Englishman is expected to say what he means. I had no idea that his "method as set forth in his November letter," and what I suggested, were the same. His method made summer-fallowing superior to everything else. I entirely repudiate the utility of the plan, while neither himself, nor the advocate of steam ploughs, even so much as hinted at the smothering-out system. Therefore I must contend there is as much difference between the two methods as there is between the two methods used by the dog and cat in catching a mouse. The canine goes to work in a most resolute and laborious manner, and sometimes will continue for days successively, using the different tools at his command, such as teeth and claws, but more frequently gives up the hard job as a bad case, and so fails in his undertaking. The feline goes about the business just the very opposite of the canine, and, by waiting only a short time, the prey comes out from sheer necessity, and the feline pounces on it without spending any labour at all. I hope, by being allowed to speak twice, I shall be better understood.

I think my system might commend itself to all, on the score of economy at least, so far as to induce a trial, because no one can lose by it; and, permit me to say, no one will fail in accomplishing the object sought by the trial. But I fail to see anything new in P. S.'s "method" of fallowing, as set forth in his November letter; and why is it now put forth as a panacea for the evil? The simple routine of farmers in this locality for the past thirty or forty years (as I learn) is to sow peas, wheat, oats, (and of late years) barley, seed with timothy or a mixture of clover and grass; and every year it is held essential to good farming to cultivate a fallow. This routine does not differ, as I can see, from the "method" set forth by P. S. in the November letter. Then in favour of the plan recommended by myself are the aged and grey-headed, while the disastrous consequences of careless or bad farming would afford additional evidence on my side. I have seen the seed grain that was to precede the timothy crop mixed with not less than from twenty-five to one hundred thistle-heads, and plenty there are who seem so thoroughly ignorant about thistle-seeds growing, and consequently give themselves no concern about the mixture of thistle-heads with such seed grain. Such parties may, perhaps, fortify themselves in this careless practice by quoting our friend's dictum, that "not one in a million of thistle seeds ever grows." This class of farmers are "neither few nor far between." They have long since cut down their last stick of timber, and have not another fresh field to break up; their whole farms are being "run out," and the "plaguey" thistles are overrunning everything. As a very general rule, we see such farmers' stocks thrust out on the highways, "to pick about and get a little" of what they can find even before the snow is gone, because, we are told, "hay runs short, straw is run out (too much has been sold, perhaps), and roots didn't grow any last year, or it pays better to sell than to feed them." Yet, talk to these men about doing away with the fallow system, and you touch them in a tender place. If any were to ask me, what they could do with their land without fallowing, my answer would be, give it to some one (and four dollars per acre with it) to take it off your hands for the year, who would use it properly, rather than abuse it yourself by cultivating a fallow. Or, secondly, why not have a field of a clover lay to plough down after the first or second crop? or, thirdly, as a last and desperate recourse, why not have ten acres of roots? If it produced only two hundred tons it would pay better than cultivating a fallow; it would furnish abundance of food for their half-starved cows in the spring, and do away with the necessity of selling their *baby* calves at from twelve to twenty days old. They might then feed and fatten them to the age of eight or ten weeks, when the meat would have passed a transition state to something wholesome and nutritious. Then one-fourth of the calves that are now slaughtered would suffice, and the farmer might raise not less than four times the stock that he now does, and the Province of Ontario might become a great emporium either for live or dead stock; its soil and sunny seasons being so pre-eminently suited for the growth of all the roots, as well as cereals, that any farming community can need or wish for. The practice of growing roots instead of cultivating fallows would enable the farmer of one hundred acres to keep an extra man and boy, and (in many cases

that I have seen and known) he might spare the housewife from such laborious work as pitching whole fields of grain, climbing a loft to throw out a load of hay for market, or taking to the scythe to help mow a compound crop of grain and thistles, besides attending to the cows and pigs, &c. All this, over and above the whole weight of household duties, entirely devolving upon her unwearied exertions. Allow me to refer once more to the words already quoted, viz., "It is reasonable to suppose, not one thistle seed out of a million ever grows." This statement I consider is fraught with mischief, and is a serious error. To fully explain and explode such a mistake would require a separate article. But for the present I will only ask in reference to his own method of destroying thistles, at what cost has it been achieved. The loss of a year's crop, added to the expense of cultivating his fallow, say $20 per acre, which for thirty-six acres amounts to the considerable sum of $720. This method carried out through a hundred acre farm would make up the snug little sum of $2000. This in a financial point of view amounts to something. To fallow a tenth part of the arable land now under cultivation every year would enable the farming community to count their losses by scores of millions. I challenge P. S. (or any of his numerous followers) to show how land is benefitted by fallowing. I have one little case to report, and would that it were so perfect a success as the thirty-six acres of P. S. I had a piece of land cut off by a swamp, and it was some years before I could come at it to seed it down. This piece of land was thoroughly infested with thistles. I never attempted by fallow, or otherwise, to destroy them (only keeping them from seeding). The land was ploughed in 1866; sowed with oats, and seeded with clover, and mowed twice in 1867, and in the third week of May, 1868, when thistles were generally from six to nine inches high, I made diligent search for thistles, and could find only just two, and those miserably weak, and not more than from two to three inches high, and they grew on a spot where the clover was a little thin. I almost conclude that had the clover lay been ploughed in the fall, these two might never have been found to have told the tale. In your note, Mr. Editor, attached to Mr. Hammond's enquiries, I think you have illustrated and placed the subject in a very intelligible position, by stating the *partial* success of your fallowing, and what you might reasonably expect in another year, namely, success in the perspective, but never in the possessive. After fallowing and seeding with timothy, thistles will surely spring up again, (the country being full of flying seeds.) Then what is to be done? I suppose the reply will be, fallow again, to be sure. Twenty-five years ago, demagogues in the old country got a considerable hold on their ignorant followers by persuading them that the best thing to put the whole nation to rights was to divide the property of the country, and to make all men equal. A gentleman said to Pat, "suppose it were so; in twenty-four hours there would be great difference again, for some would save and some would squander; then what could be done?" "Nothing aisear, yer honour; divide again."

PUBLICOLA.

Young Grass for Hay.

MR. C. L. FLINT, Sec'y Mass. Board of Agriculture, in 1862 visited several European States. The leading object of his visit in "those foreign lands," was to make himself acquainted with the agricultural practices of the farmers in the "old world States." His mission was a success, the results of which are published in the Annual Report of the "Agriculture of Massachusetts, 1862." In writing respecting the grass or hay crop in Lombardy, (Italy,) he says:—

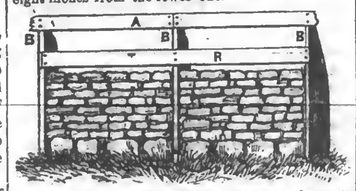
"To me, previous to seeing this fertile country of Lombardy, made fertile wholly by its admirable system of irrigation, the results that I had frequently read of—seven, eight, and nine cuttings a year—always appeared chimerical, but after travelling through the length and breadth of the watered district, I am prepared to believe that an enormous quantity of grass can be cut from it. Another thing has impressed me strikingly here, and that is, that the Italians understand the period at which grass should be cut, to make the most of it, *better than we do*. I nowhere saw grass allowed to stand even into blossoming; it was cut in a very green and succulent state, when full of its sweet young juices. In hundreds of instances, perhaps thousands, I saw men and women—mere frequently the latter—mowing grass less than six inches high, often less than four, and very often, and in many countries, cutting grass that our farmers would never think of cutting. So careful and so saving are they in all parts of the continent, that grass is cut very green, very often, and very close to the ground, almost universally. But they often apply a dressing of liquid manure immediately after cutting, and I saw it in innumerable instances carried out upon the backs of women, and applied by the slowest of processes, distribution by hand, often making an extremely bad smell, to be sure, after it was first applied, but causing a wonderfully rapid start and growth."

Bag-Holder and Tunnel Combined.

THE engraving represents the simplest, most convenient, and altogether the best arrangement for holding bags while filling with grain, meal, or anything else put into bags. It consists of a metallic tunnel, to which are attached four steel hooks, which hold the mouth of the bag distended in such form as readily to receive the grain from the measure or shovel without the inconvenience of filling the bag alone.—(*Prairie Farmer.*)

Wall and Board Fence.

IN many localities it is desirable and convenient to build a fence, the lower portion of which is stone and the upper of boards. I do not know of one that possesses so many advantages as the one shown herewith. The posts, B, B, B, are made from plank, two inches thick, and one foot wide, and of any length to suit the height of the fence. The portion above the wall is tapering, as shown in the figure R is a board six inches wide, the lower edge of which is nailed on the post, two and a half feet from the ground. A is a board four inches wide, and placed eight inches from the lower one.



Directions for building a Fence.—First, set the posts B in the ground; two feet will be about the depth; nail on the boards, or the upper one at least, when you are ready for laying up the wall. The nearness of the posts to each other, and the width, will enable you to use a great many round or coble stones in its construction, with a certainty of their remaining.

The superiority of this fence over the common round post and wall-fence, consists in—1. The wall never falls or tumbles down around the post, as they are laid between, and not around the posts.—2. The post never heaves by the action of the frost, as the stones in the wall hold it with the power of a vice, so to speak.—3. I consider this the only cheap and durable plan by which a half-wall fence can be constructed, and it looks neat and is substantial, as I can testify from examination.

Barrington, Yates Co. N. Y. L. D. SNOOK,
in *Country Gentleman.*

Flax Culture.

To the Editor of THE CANADA FARMER:

SIR,—It is now some time since I troubled you with a few lines on this subject, and I have much pleasure in handing you a letter from a gentleman of well-known experience, not only in the manufacturing of machinery used in this department, but a practical spinner and weaver, by which you will see he points out the plan whereby this branch of industry can still be successfully carried on in Canada.

We have not had a season during the last ten years as favourable for a flax crop as the present, and those who still continue to grow it in the counties of Waterloo and elsewhere, will find the crop remunerative. There need be little fear on the part of the manufacturer if he will only follow the advice offered by Mr. Walker in the accompanying letter.

J. A. DONALDSON.

Toronto, June 22, 1868.

"To J. A. DONALDSON, Esq.

"DEAR SIR,—I was very sorry to hear of the misfortune at Streetsville, and since arriving here I have heard that the linen mill of Messrs. Elliot, Hunt & Co., of Preston, has been given up. What are the flax-growers of Canada going to do for a market for their produce? There is now no consumption to speak of in Canada—the distance and expense of carriage prevents the sale of it in England. They have therefore to depend entirely upon the demand in the United States, which is liable to be stopped any session of Congress by a heavy additional duty. Does it not appear that the best way of securing a market is to manufacture in Canada the flax grown in Canada? But it will be said, what encouragement is there for men of capital to invest in a business, seeing that those who have attempted it in this country have not succeeded. I answer that not one manufactory has been planned, arranged, or managed in a way to succeed. They would not have succeeded anywhere, and I am sorry to say it, because the proprietors, in two instances at least, deserved success, having spared no pains or expense to render their works efficient, but they were misled at the very beginning. There is no reason whatever why linens cannot be made in Canada. The material produced in the country is quite good enough for the usual linens used. The expense in freight, duties, &c., on imported goods would more than make up the difference in the cost of labour, and now that cotton has advanced from 7*d.* to 12½*d.* per lb, in Liverpool, with every indication against a reduction below the latter figure, there is no doubt any party going into linen manufacturing in this country, on the same plan as that adopted in Europe, would make the business answer well. Should you wish to write me at any time, please address to care of Messrs. T. & W. Hunton, Ottawa, C. W., or to Box 4181 Post Office, Boston, Mass.

"JOHN WALKER."

Greasing Wagons.

BUT few people are aware that they do wagons and carriages more injury by greasing too plentifully than in any other way. A well-made wheel will endure common wear from ten to twenty-five years, if care is taken to use the right kind and proper amount of grease; but if this matter is not attended to, they will be used up in five or six years. Lard should never be used on a wagon, for it will penetrate the hub and work its way out around the tenons of the spokes, and spoil the wheel. Tallow is the best lubricator for wood axle-trees, and castor oil for iron.

Just grease enough should be applied to the spindle of a wagon to give it a light coating; this is better than more, for the surplus put on will work out at the ends, and be forced by the shoulder-bands and nut-washers into the hub around the outside of the boxes.

To oil an iron axle-tree, first wipe the spindle clean with a wet cloth with spirits of turpentine, and then apply a few drops of castor oil near the shoulder and end. One teaspoonful is sufficient for the whole.—*Rural American.*

Canadian Natural History.

Canadian Ducks.

THROUGHOUT nature, and especially among animated creatures, there is everywhere manifest, along with an almost endless variety of detail, a beautiful uniformity of type. This is especially remarkable in the great class of animals to which hitherto the brief notes in the Natural History Department of the CANADA FARMER have been confined, namely, the *Vertebrata*. Throughout the whole of this class we trace the same general principle of structure, and, indeed, the very same parts and members endlessly modified to adapt the form to the peculiar requirements and habits of the individual. Take, for instance, the fore-arm, and notice how wonderfully the same fundamental type is maintained, and yet

modified in the different orders of animals. The same variety, with uniformity, is observable in the different members of each order. Thus, among birds, the general character of whose form fits them for the air, some are adapted for spending a great part of their time seeking their food and taking their rest on the ground, having recourse only occasionally to their powers of flight; whilst others pass half their lives on the wing, and rest only at night amongst the trees; and another tribe again are specially fitted for floating on the surface of the water, where they find their food, and revel in the enjoyment of their appropriate element. Here, while the bird type is perfectly preserved, we see the breast broadened, and the whole body flattened to fit them for floating, while special arrangements are made in the plumage for throwing off moisture, and in the feet, forming jointed and flexible paddles, for progression through the water, or rather on its surface. The whole tribe of waterfowl are singularly beautiful and graceful creatures, and there is scarcely a more interesting study to the naturalist than the characteristics and habits of this extensive portion of the feathered race. Abounding as Canada does in lakes and streams, we should expect to find numerous representatives of the order amongst our native species or occasional visitors, and in this expectation neither the naturalist nor the sportsman will be disappointed. Canadian Natural History has hitherto had but few expositors, and, doubtless, there are many species of animals to be found that have not yet been enumerated in the Fauna of the country; but in the admirable list furnished by Professor Hincks, we find there are no less than thirty-eight species of the Duck tribe alone mentioned as being found more or less generally on Canadian waters. Specimens of nearly this number of distinct species of Duck were sent by the Board of Arts, along with other birds, to the Paris Exhibition. We have selected four of these for notice and illustration, namely, the Mallard (fig. 1), the Shoveller Duck (fig. 2), the Widgeon (fig. 3), and the Summer Duck or Wood Duck (fig. 4). These are all remarkably beautiful and characteristic species. The drawings have been made from specimens in the Toronto University Museum, or from the illustrations in Wilson's American Ornithology. To this excellent work we are also largely indebted for the description of the birds.

All the different varieties of wild duck are in their natural state extremely cautious birds, alert and quick, and difficult to approach; either lying closely concealed among the reeds of their favorite marshes, or taking suddenly to rapid flight upon the least alarm. They are greatly sought after as supplying a delicate article of food, and are sometimes, on this account, mercilessly slaughtered by sportsmen, or by most unsportsmanlike hunters. Various methods have been, and are still, employed in different countries to capture them. In India and Ceylon, we are told, the natives catch them in a curious manner. A man covers his head with a calabash, or large gourd, perforated with holes to see through, and thus disguised, wades into the water to such a depth that only his head is above the surface, and approaches right into the midst of the birds, who perceiving nothing but apparently a floating calabash, do not take alarm even when one after another of their number is caught by the legs, drawn under water, and attached to the girdle of their treacherous destroyer. A common method of decoying them is by the use of wooden figures shaped and painted to resemble ducks. These "dummies" are floated on the water, and enticing the wild birds, bring them within gunshot of the concealed hunter. Sometimes a frame, with a number of these figures upon it, is attached to the bow of a skiff, which is itself decked down to the water's edge with reeds, rushes, and coarse grass, so as to present the appearance of a small island, with ducks swimming about it. Thus concealed, the gunner can float his skiff within easy range of the birds, and take a murderous shot at close quarters. An elaborate account is given in Berwick's History of British Birds of the method practised chiefly in the fen districts of Lincolnshire, and called the "Decoy." A long curved ditch is dug from the edge of the lake inland. Over this ditch, which is wide at its junction with the lake, but gradually narrows towards the other extremity, is stretched, on arched hoops of wood, a net, terminating at the narrow end in a sort of purse or *cul de sac*. Along the side of this curved ditch are placed a series of screens formed of reeds, behind which the trapper hides, showing himself now and then to drive the birds toward the narrow extremity of the ditch. He is usually assisted by a trained dog, and also by tame ducks, employed to entice their wild congeners into the fatal snare. Vast numbers used to be caught in this way in England. In one season as many as thirty-one thousand and two hundred ducks have been sold in London alone from ten of these decoys near Walnfleet, in Lincolnshire. We trust that in this country a wise policy will protect our native waterfowl from any such wholesale destruction; and especially that during their breeding season they will be left unmolested.

In the present article we can only notice very briefly the Canadian species represented in the accompanying illustration. The most striking figure of the group is the Mallard (*Anas boschas*), the parent of the common domestic duck. In colour and plumage some of the domestic breeds very closely resemble the original wild stock, but in other respects are sadly degenerate. The duck of the

poultry yard is contented and happy enough truly, but inert and slow, waddling in its gait on land, while its wings, from disuse, can hardly raise it above the ground. The wild duck of the lake is quick and wary, full of life and spirit, and springs into the air when alarmed with a power of flight at once strong, rapid and enduring. Nothing can be more beautiful than the form, bearing, and plumage of the Mallard, especially when seen floating on its favorite element. Its length is about twenty-four inches. The general colour is too well known to need particular description. The bill is greenish yellow; irides hazel; the head and neck are a rich, shining green, abruptly terminated by a collar of white. The back is chestnut brown, deepening into black; the four central tail feathers are velvety black and curled up; the rest of the tail is of an ashy grey colour, edged with white. The greater wing-coverts are marked with a bold white bar, and tipped with velvety black, and the wings are beautifully coloured with shining purple, snow white, and velvet black. The colour of the female is mottled brown, the feathers bordered with a yellowish tinge.

The summer residence of this duck is in the northern latitudes. The female selects for her nest the most solitary recesses of the marsh, among reeds and rushes, where she lays from twelve to sixteen eggs of a greenish tinge. Occasionally, however, she seeks some sheltered woodland nook at a considerable distance from water, and there hatches her young, which for some time at least afterwards she nightly takes back to the same spot. Audubon mentions meeting on one occasion a duck thus leading her brood into the wood. His well-trained dog, at the master's bidding, brought all the young ones to him without hurting them; but the piteous behaviour of the bereaved parent moved the compassionate heart of the naturalist to restore the ducklings to their mother, and thus to make her, as he believed, a grateful and a happy duck. Instances are recorded in which the bird has so far departed from its usual habits as to build its nest in a tree, and several notices of a similar occurrence have recently appeared in the London *Field*. The Mallard is certainly a voracious bird, and by no means choice in its feeding. They are omnivorous; and in a domestic state, whatever of the wild spirit and activity they may have lost, they retain, at least, their enormous capacity of eating. On this account some farmers do not consider them profitable inmates of the poultry yard. They possess, however, many good qualities that well repay the trouble of keeping them. They are expert fly-catchers, and render excellent service by destroying vast numbers of insects, slugs, and other pests of the garden and fields.

The next species in our illustration is called, from the peculiar shape of its bill, the Shoveller Duck (*Spatula clypeata.*) This peculiarity in the bill, and the striking plumage of the bird, will always distinguish it from every other species and render its identification easy. It is liable, however, to considerable variety in the colour of its plumage. It is about twenty-two inches long. The bill, of a brownish black colour, is remarkably broad towards the extremity. The head and upper part of the neck are glossy green; the rest of the neck and breast white. The belly is reddish chestnut; the flanks are brownish yellow, pencilled transversely with black; between them and the vent is a white band. The back is dark brown; the wings are beautifully and somewhat variously colored with white, blue, green, and black. This bird frequents the muddy shores of lakes, and feeds on small worms and the larvæ of insects, which it sifts by the peculiar construction of its mandibles from the muddy water. Along the edge of each mandible is a row of comb-like teeth, closely fitting into each other, and forming a kind of sieve which admirably serves the purpose just mentioned. Each mandible is also grooved to receive the pectinated teeth opposite, when the bill is closed. Like the preceding species, the female usually builds her nest on the ground, in the secluded recesses of the marsh, concealed by reeds and rushes. She lays about ten or twelve rust-coloured eggs. The young are at first odd-looking, ungainly objects, the strangely developed bill appearing out of proportion to their downy little bodies.

Behind the Shoveller in the illustration, appears a somewhat smaller, less strikingly marked, but very elegant species, the American Widgeon, (*Mareca Americana*). A sober grey predominates in the plumage of this graceful bird, but beautifully varied with wavy lines, giving to the surface a softly shaded appearance, and rendering this species one of the most elegant of the tribe. The widgeon, or as it is frequently called, the Bald Pate, accompanies another well-known species, the Canvas-back Duck, so abundant in Chesapeake Bay. It is extremely fond of the tender roots of a particular aquatic plant on which the Canvas Back usually feeds, and for which the latter dives to the bottom of the water. But as the Widgeon never dives, its only means of procuring the coveted delicacy is to watch the movements of its bolder cousin, and, as the latter emerges after its plunge, to snatch the morsel from its beak, before it has well-recovered its breath or dashed the water from its eyes. On this account there is perpetual contention between the two species, the smaller of which, with the ordinary philosophy of thieves, considers discretion the better part of valour, and always retreats when attacked; only, however, to watch its opportunity for another petty raid on the very next occasion that presents itself. This species does not usually breed in the States, the southern portion of which it leaves in April, and appears in May along the coasts of Hudson's Bay. It is about twenty inches long. The bill is slate-coloured, with the nail black; the crown of the head is of a creamy white. Beneath this a band of glossy green, speckled with gold and purple, extends back from the eyes to the middle of the neck. The throat, chin, and sides of the neck are a dull, yellowish white, speckled with black; the belly is white; the breast and hinder part of the neck are of a bay tint, crossed with wavy lines of black; the back and scapulars, of of a darker hue, are also crossed with wavy lines; the lower part of the back is dusky.

The last species we shall notice is perhaps the most beautiful of our native ducks. It is called the Wood Duck (*Aix sponsa*), from its practice, not occasional, as in the case already mentioned, but habitual, of making its nest in the hollow of a tree, or sometimes even in a fork of the branches. It is also called the Summer Duck, especially in the adjacent States, because it remains and breeds there during the Summer season. This beautiful species is about nineteen inches in length. The bill is red, margined with black. The crown of the head and crest are of a rich glossy, bronzed green, ending in violet. A line of pure white extends from the upper bill over the eye; another white line meets this behind the eye, and both join their long pendent plumes with the green and violet ones. The cheek and sides of the upper part of the neck are violet; the chin, throat, and collar are white, the snowy band curving up in the form of a crescent. The white collar is bounded below with black. The breast is dark violet brown, marked on the forepart with minute triangular spots of white, increasing in size till they spread into the white of the belly: the side of the breast is bounded by a large crescent of white, and this again by a broader one of deep black. The flanks are marked by broad semi-circular lines of alternate black and white. The tail coverts are long, and hair-like at the sides, of a deep black blue glossed with green. The back is a dusky bronze, and the scalpulars are black. The tail is tapering, glossy green above, dusky below. The primaries, of a dusky silvery tinge, are tipped with violet blue; the secondaries are greenish blue, tipped with white. The legs and feet are yellowish red. This description, taken from Wilson, will give some idea of the singularly beautiful plumage of this remarkable bird. The specimen in the University Museum was very much damaged by moths. The nest of the Wood Duck contains about thirteen eggs, rather smaller than a hen's egg, perfectly oval, in colour of a creamy polished white, much resembling old ivory. The male is usually perched near while the female is laying or setting. When the young are fully hatched, the mother carries them in her beak, either by the back of the neck or the wing, from their elevated nest to the ground, and leads them off to the water. These birds do not occur in large flocks, but generally in pairs. They are easily domesticated, and become very tame, forming most beautiful objects to enliven the surface of ornamental waters in private grounds. The Indian frequently decorates the Calumet, or Pipe of Peace, with the skin from the Wood Duck's head, the most beautifully painted object that he could select in all his wide range of search.

We must not extend this notice by any description or even allusion to other species. Most of the family are migratory, and their movements are familiar harbingers of spring or warnings of approaching winter. The flight of the Mallard especially is swift, strong, and well sustained, its speed being estimated by Audubon as not less than a mile and a half in a minute, and, in long journeys, amounting to as much as one hundred and twenty miles in an hour. The instinct or faculty which guides their swift, extended, and unerring flight through the trackless air to distant regions, where both the temperature and means of subsistence are in accordance with their wants, is among the wonderful provisions of nature, which have ever called forth the admiration of the naturalist and the poet, and teach us much of the goodness of the universal Father, whose care and "tender mercies are over all his works." This lesson is pleasingly embodied in the beautiful lines of William Cullen Bryant, "to a waterfowl."

Whither, midst falling dew,
While glow the heavens with the last steps of day,
Far through their rosy depths dost thou pursue
Thy solitary way?

Vainly the fowler's eye
Might mark thy distant flight to do thee wrong,
As, darkly painted on the crimson sky,
Thy figure floats along.

Seek'st thou the plashy brink
Of weedy lake, or marge of river wide;
Or where the rocking billows rise and sink
On the chafed ocean side?

There is a Power whose care
Teaches thy way along that pathless coast—
The desert and illimitable air—
Lone wandering, but not lost.

All day thy wings have fanned,
At that far height, the cold, thin atmosphere,
Yet stoop not, weary, to the welcome land
Though the dark night is near.

And soon that toil shall end;
Soon shalt thou find a summer home, and rest,
And scream among thy fellows; reeds shall bend
Soon o'er thy sheltered nest.

Thou'rt gone; the abyss of heaven
Hath swallowed up thy form; yet, on my heart
Deeply hath sunk the lesson thou hast given,
And shall not soon depart.

He who, from zone to zone
Guides through the boundless sky thy certain flight,
In the long way that I must tread alone,
Will lead my steps aright.

☞ The English sparrows which have taken so kindly to the squares and parks of New York, are now numerous in Newark and other neighbouring cities, and by their hardihood and cheerfulness under adverse circumstances, put to shame their cousins of American birth.

Stock Department.

Breathing.

A CONSTANT process of change is one of the essential and mysterious elements of life, even in its lower forms, and becomes more marked in the higher organizations. In man and those animals nearest to him in physical structure, this process of change is very active. Hourly and momentarily some portion of the material of the body is being removed, and its place supplied with new matter freshly endowed with vital properties. No part of the body remains the same for two days together, and it is not in any case a long period that is required to change completely every atom of our frame, so that, while through all the transformation our identity is wonderfully preserved, the component materials are altogether new. In consequence of this perpetual waste and repair arises the necessity of furnishing new matter to be converted into living tissues, and take the place of that which has been removed. This is effected in large measure by food, and the process of digestion, whereby so much of the food as is fit for nourishment becomes converted into blood; and out of this fluid the tissues of the body are continually renovated. But digestion is far from being the only function employed in this work of restoration. Indeed, while essential for the maintenance of life, it is intermittent in its operation, and may be suspended for a considerable time without serious inconvenience. There is another function concerned in the process, and which is constant, and cannot be interrupted, for many seconds, without endangering life. This is the function of Respiration, or Breathing. By the process of digestion fresh blood is formed; by that of breathing the impurities of the blood are continually removed, and fresh vivifying material added to it. The impurities are contracted by the blood being charged with effete or waste matter, and the office of breathing is to supply the vital fluid with a fresh element that, while it helps to build up the system, unites chemically with the waste material and removes it from the body. The agent by which this essential restoration is effected is the element oxygen, which plays so important a part throughout the material world. This element, it is scarcely necessary to inform the reader, is a component part of atmospheric air, the grand reservoir, so to speak, in which it is stored. It constitutes one-fifth of the atmosphere, the remaining four-fifths being composed of a comparatively inert substance, nitrogen, whose chief office, as it exists in the air, may be said, speaking generally, to be that of diluting the oxygen. One part of the process of breathing, then, is a mechanical agency, that of bringing the blood and air together. There is, besides, another part, the chemical effect resulting from the contact. Let us consider first the mechanism of respiration.

We have seen, in examining the circulation of the blood, how this fluid, after traversing the system, returns to the right side of the heart, and is thence sent into the lungs, where it is distributed in a very fine network of delicate tubes, or capillary vessels as they are called, the coats of which are extremely thin and permeable to air, though they do not allow the escape of their liquid contents. Now, the air apparatus of the lungs is, in its essential nature, nothing more than a membranous sac or bag, communicating by a narrow opening with the air, and having its walls or coat completely surrounded by these delicate and closely set blood vessels. There are, then, between the blood and the air, two membranes—the coat of the capillaries and that of the lung sac—but each is extremely thin, and offers no impediment to the passage of air or any gas through it. It is a law affecting all gases that they tend to diffuse equally, almost as if one were a vacuum to another, and a thin animal membrane does not at all interfere with this diffusion and intermixture. It may therefore be understood that the air and blood are brought into contact. Air passes through the sac containing it into the blood, and any vapour or gas from that fluid passes out into the air. All that is essential to the lung then is, as before mentioned, a plain sac, the interior of which air can enter, while blood vessels cover it on the other side. Such, the simplest form of lung, is represented in figure 1 of the accompanying diagram, where the external line indicates the boundary of the chest, the inner line the coat of the air sac or lung, and the dark line between them the layer of capillary blood vessels.

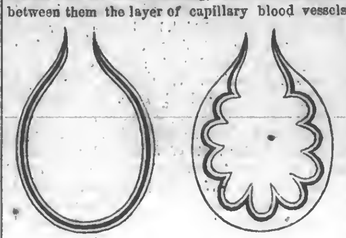


FIG. 1.

FIG. 2.

The further extension of the organ is mainly an economy of space, and is designed simply to increase the surface over which the air and blood can be brought together. Thus in figure 2 the air sac is turned in folds or scollops, whereby evidently the extent of surface is increased within the same boundary line. This is the actual form of lung in some *amphibia*, such as frogs. By still further deepening these folds a greater expanse of surface is obtained within the same external limits, as shown in figure 3. And again, by branching these deeper folds, we obtain a series of tubes ending each in a little *cul de sac*, or cell, as in figure 4. The last diagram represents the ramification of the air tubes and cells in the more complicated form of lungs, such as those of man and the higher animals. The simple principle is the same in all, a bag of air with blood vessels outside it; but in the more completely developed lungs an enormous extent of surface is secured, over which the blood and air are brought together.

Having stated the principle of the structure, let us now very briefly examine the details. We may take the human lung as the type, for the construction is precisely similar in that of the higher animals, and both the mechanism and the chemistry of the process are the same in all. Briefly to glance, then, at the anatomy of the lung, there are first the exter-

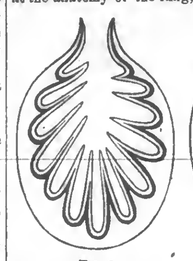

FIG. 3.

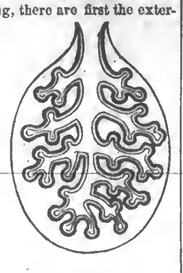

FIG. 4.

nal opening, and the tube leading from it. The latter is called the *trachœa*, or windpipe, and at its summit is placed an accessory organ, the *larynx*, or organ of voice. The trachœa is a membranous tube, kept open by a series of rings of gristle or cartilage. After it has entered the chest, the windpipe divides right and left into two main branches, and these again subdivide repeatedly, the minutest branches terminating in a cluster of small cells. These branches of the windpipe are called bronchial tubes, and the terminal sacs air cells. The cartilaginous rings are met with in the larger bronchial tubes, but throughout all of them is a highly elastic material, like that which forms the elastic coat of the arteries. This elastic tissue allows the tubes and cells to be distended, but as soon as the distending force is withdrawn causes them to collapse to their ordinary dimensions, expelling a portion of the contained air. If a lung be removed from the body after life has ceased, and inflated with air, the elasticity of its substance will, in the absence of all muscular power or any force from without, drive out again a portion of the air.

Now, we have seen that the blood is passing in a constant stream through the blood vessels of the lungs, constantly exposing, therefore, fresh fluid to the action of the air, which, as it receives the impurities of the blood, must become in turn impure. It is necessary, then, to change the air in the lungs, and this is effected on well-known mechanical principles. Take, for the sake of illustration, the simplest form of lung, the air sack, fig. 1. The chest itself is an enclosed cavity impervious to air; the lung within it an elastic bag freely communicating by an open orifice with the atmosphere. The pressure of this will necessarily fill out the internal sac, and press its sides close against the walls of the chest. Now, the chest is so constructed that its dimensions or capacity can be altered. When it is enlarged, more air will rush in; when it is diminished, a portion of the air will be expelled. This is just what takes place in ordinary breathing. The general shape of the chest is that of a hollow cone, with an arched or convex base. The ribs, placed obliquely, and muscles between them, compose the sides of the cone, while the base is formed by the diaphragm, a muscular and membranous partition, arching up, which divides the chest from the abdomen. The dimensions of the chest are altered by the elevation of the ribs, an action which increases the width of the cavity, and by the depression of the diaphragm, increasing its depth. These are muscular actions which in ordinary breathing are carried on under the influence of certain nerves without any effort of the will. This involuntary muscular action increasing the dimensions of the chest, causes air to rush in, and accomplishes the drawing in the breath, or inspiration, as it is called. As soon as the muscular action ceases, the elasticity of the lung comes into play, and, causing the tubes and cells to contract, drives out a portion of air, while, at the same time, the pressure of the external air keeps the walls of the chest still close against the boundaries of the lung. This part of the process is called expiration, and is, in ordinary breathing, entirely due to the elasticity of the lung. We can, however, by an effort of the will control these actions to a considerable extent. Expanding the chest to a greater degree, we can draw a deep breath; or contracting it by an effort, we expel the air more forcibly. We also fix the ribs,—hold the breath, as it is called,—for the purpose of making an extra exertion, especially with the arms; and we control these movements in the exercise of the voice.

The quantity of air that is taken in and expelled by the lungs in ordinary tranquil breathing varies somewhat in different individuals, but may be taken as an average in healthy adults at from twenty to twenty-five cubic inches with each act of breathing. The breathing capacity, or the largest amount of air that a person can, after a deep inspiration, expel from the lungs, also varies considerably, but maintains a curious relation to the height of the individual. Thus, the full capacity of a healthy person, five feet seven inches in height, is about 225 cubic inches. For every inch of height above this standard the capacity is increased on an average by eight cubic inches. This statement does not refer to the size of the chest, or the amount of air it will hold, but to the quantity that can be expelled by a forced expiration.

This brief and imperfect outline of the mechanism of respiration is all that our space or the scope of this journal will permit. The consideration of the chemical changes that take place in the process must be deferred to a future article.

The Dairy.

Hints on Dairy Matters.

IT is a fact too palpable for dispute, that the average of cows kept throughout the country, for milk production, is a low one. Various exceptions show what amount of milk a really good cow can produce, under proper selection, with abundant food of the right kind, and good care. With such examples as the latter for a standard, at which, in due time, we may arrive, if the proper means be taken to accomplish it, we can add twenty to fifty, or even a hundred per cent. to the production and profit of our cows, with little additional cost. We have known—we now know—men who derive an income from a single cow, in the sale of her milk, beyond the annual cost of her keeping, besides supplying their own families with milk and cream, and sometimes butter. The average of our milk dairies, as they are usually kept, is not over five hundred gallons a year; of the butter dairies one hundred and fifty pounds; of the cheese dairies, three hundred and fifty pounds per cow. These averages can be increased full one-half, in the simple items of selections of cows, more suitable and abundant food, and increased care in their keeping. The requirements to constitute a really good dairy may be somewhat more expensive, but much less so in proportion to the additional yields to be obtained from it, than in the loose and negligent way in which they are now managed. All these improvements we have suggested; and why not at once adopt and act upon them? A wise forecast will do so.

The establishment of cheese and butter factories has improved the quality of those articles, and cheapened their production. The tests of science, and accuracy of method, have been adopted in them, raising their flavor and quality to the highest standard, both at home and abroad. Knowing, thus, what has been accomplished in these particulars, we have every incentive to a still further improvement in the material—cows to furnish these most satisfactory results. Dairy factories, aside from improving the quality of their products, and increasing their prices over the old household way of making them, have accomplished a most beneficent and merciful mission, in relieving the wives and daughters of our dairymen of a routine of slavish and most wearing labor. The life of a household dairy-woman is toilsome in the extreme. Perpetual watchfulness, anxiety and work throughout the dairy season, frequently beyond her physical endurance, has been her destiny—over the cheese-tub, and shelf, the churn and butter-bowl—to say nothing of her labours in the milking yard, over the wash kettle, and scrubbing brush. No relaxation whatever is permitted. Necessity knows no law, nor mercy for those patient overworked solaces of the household. Even hired female labour is impatient of the task, and shirks it, except at the highest wages, and for a limited period.

We trust that dairy factories may soon become *the rule*, and the household thus relieved of an intolerable drudgery. In factories, the strength and ingenuity of man is employed almost solely, and the female assistance is so mitigated in its toil, as to be easily and cheerfully accomplished. In the spirit of drowsy Sancho, who invoked blessings on the man who invented sleep, we utter unbounded thanks to the benign brain of him who contrived the cheese and butter factory!

Every farmer, every owner of a cow in the land, should take a pride and a pleasure in having her the best, most useful of her kind. There is no more comely creature living than a fine, well developed cow or heifer, a steer or an ox; and the whole majesty of the bovine race stands forth in a well-bred, stately bull, of an established approved breed. No higher ornament to the farm, the park, the paddock or the stall, can be found than in them. Their presence is ever a pleasure to those who appreciate their value, whether in the humbler walks of rural life, or enjoying the highest social or public distinctions.—*Allen's American Cattle.*

New and Old Rennet---Curing it.

IN answer to an inquiry on the subject, Mr. Willard says, in the *Utica Herald*:

We do not believe new rennet to be so good for cheese-making as old rennet. We have experimented a great deal, first and last, with rennet in the manufacture of cheese, and we have invariably found old rennet, properly selected and cured, of more strength—that is going further in coagulating milk than new rennets. Again, new rennets are apt to produce a more active fermentation of the cheese while curing, causing it to huff or swell, and no cheese that huffs but is more or less injured in flavor. There is great difference in the power of different rennets to coagulate milk, not well understood or even to be fully explained by the chemists. Dr. Voelcker, the celebrated English chemist, after making numerous analyses of rennet, says the precise nature of rennet and its action on milk is yet a mystery, and that we have not even a name for its coagulating principle. We know from experiment that a superabundance of salt in curing rennet neutralizes in part the coagulating principle; hence, in curing rennet, no more salt should be used than is absolutely necessary to keep the skins from tainting. We have no doubt but that rennets which often prove weak in strength have been injured by over-salting, the soda in the salt not only neutralizing the active principle in the rennet, but having the same effect upon the lactic acid in the milk.

In saving rennet, we are of the opinion that the Bavarian method will prove of great value to our dairymen. We have adopted this method of curing in our own dairy, and we find it not only of less trouble, but the skins are more perfectly cured and more easily packed away than when salted in the usual way. We have heretofore explained in the *Herald* the manner in which rennet is cured under the Bavarian method, but as some may have overlooked our remarks we repeat again. The curing consists in simply turning out the contents of the skin, wiping off all specks or dirt with a cloth, and then blowing up the skins or filling them with air like a bladder. The ends are tied with a string, and a little salt applied to this part only. The skins treated in this way soon dry out perfectly, and are as sweet and clean as can be desired. If there is any truth in the assumption that salt neutralizes the action of the rennet, then rennets treated on the Bavarian plan must be much more effective than those cured in the old way. Again, when the rennets on the Bavarian plan are dry, the air may be expelled and the skins packed away in small space, and can be kept clear of bugs. The trouble with salted rennets is that the salt in wet weather accumulates dampness, and if particular care is not taken to keep them in a dry place, they drip, and consequently lose strength. Rennets saved on the Bavarian plan of curing, are said to be stronger as well as sweeter than any other. We can not say positively, from our own experience, that this is so, but we are testing the method, and shall be able in time to give the result. So far we approve of the system, and recommend it to the attention of dairymen.

To Make Cows Give Milk.

A writer who says his cow gives all the milk that is wanted in a family of eight persons, and from which was made two hundred and sixty pounds of butter in the year, gives the following as his treatment. He says: "If you desire to get a large yield of rich milk, give your cow, three times a day, water slightly warm, slightly salted, in which bran has been stirred at the rate of one quart to two gallons of water. You will find, if you have not found this by daily practice, that your cow will gain twenty-five per cent. immediately under the effect of it, and she will become so attached to the diet as to refuse to drink clear water unless very thirsty, but this mess she will drink almost any time, and ask for more. The amount of this drink is an ordinary water pail full each time, morning, noon and night. Your animal will then do her best at discounting the lacteal. Four hundred pounds of butter are often obtained from good stock, and instances are mentioned where the yield was even at a higher figure."—*Wisconsin Farmer.*

How to Prevent Badly Weaned Calves from Sucking.

IF you or any of your readers have been pestered with the contrary wilfulness and persistence of a badly weaned calf, as I have been for the past twelve months, they will be glad to know that a common snaffle bit will cure the beast most effectually. A colored man, George Daniels, who has charge of my stock, claims that he "is de first chap who invented dat dar," and it has certainly answered the purpose with a two-year old heifer who has given George a "site of trouble" for the past year. He tied a strong twine-string to the bit, and thus fastened it on her head as a bridle would be put on any animal. It does not interfere materially with the feeding of the beast, and I have no doubt will be an easy and thorough remedy for the trouble, either with calves or with cows disposed to milk themselves.—*Cor. Country Gentleman.*

How Country Folks Cheat City Folks.

IT is universally supposed that country farmers are an honest race; but a *city retail butter dealer* makes a grievous complaint as follows:

"It does seem to me as though the dairymen were determined to add in every possible way to the weight of their butter, as they manage in more than one way to defraud the retail dealer. I consider it sharp practice to overload butter with salt; also to put from a sprinkle to a half-pound in the bottom of the tub, and from three-quarters to a pound and a half on the top of the cloth covering the butter.

"It also appears as though the maker forced all the water in the tub with the butter that was possible.

"In fact, to sum up, butter-makers appear to think they have a good thing of it selling salt rags and water at the price of butter. My advice to producers and dealers is, to sort colors; do not put so much salt between layers, and in particular keep their kerosene in some other place than where they pack their butter."

☞ A woman in Brooklyn purchased a quart of milk, and found a small fish swimming in it. The milk-man stated he thought the cow must have swallowed the fish.

Veterinary Department.

Injuries and Diseases of the Horse's Foot.

AT all times, but more particularly during the dry, hot months of summer, the foot of the horse is very liable to injury and disease. When the roads are dry and hard, the jar and concussion occasioned by fast travelling is very great, the hoof also becomes hard and brittle, and frequently splits or cracks, and owing also to small rolling stones the sole is frequently bruised, and these injuries, when neglected, often extend and give rise to more serious disorders. When horses are used on the farm or on soft roads, the feet are not very liable to concussion, but when they are driven a distance upon a hard road, and, perhaps, with shoes that are pressing upon the soles, then the lamina, or sensitive parts become bruised and congested, and the horse will go slightly lame. At this season, many horses are lamed in the above manner. The lameness may be produced after one drive. Frequently horses are purchased in the country and then brought to town, when they are driven for a few days on our hard roads and streets without their feet being attended to in the least, and the shoes lying upon the sole; as a consequence of the jar and concussion, the horse will begin to stumble and falter in his action, which is most observable when he goes out of a morning, or after standing some time. What we refer to is to be met with mostly in the front feet, because the fore feet are raised higher from the ground, and are brought down with much greater force, therefore they suffer more frequently than the hind feet. From this continued buttering, the laminæ are strained and congested, and the horse goes lame, especially if he carries any weight upon his back. When standing, he will keep shifting his feet; the heels will be hot, and the fetlocks somewhat puffy, and in some instances the legs will swell upwards towards the knee. The foot taken up and the sole tapped with a hammer will at once cause him to evince pain, shown by suddenly jerking the foot. When these symptoms are observed, the horse should be at once laid off work for a few days; the shoes should be removed, and the feet cooled by means of wet cloths wound round the feet, or by keeping him standing for several hours daily in moistened clay; he should also have a mild dose of physic, and be restricted to a cooling diet, as bran mash, or, when it can be procured, green clover or vetches. In the course of eight or ten days, he may be re-shod, and if he evinces the least tenderness leather shoes should be applied, and also a stopping of tar and tow. By so doing, the sole is kept soft and moist, and the jar and concussion are to a great extent removed.

The Causes of Disease.

DARKNESS AND DIRT.

SOLAR light consists of luminous, chemical and calorific rays, and appears to be almost as important for the well-being of animal as of vegetable life. With what unmistakeable satisfaction do all the domestic animals bask themselves in the sunshine! In its brightness and warmth all creatures seem to revel. Yet horses in coal pits and mines, deprived of its cheering influences, if otherwise well managed, do not seem specially liable to any particular diseases. Young animals deprived of sunlight probably suffer more notably than adults, are apt to become puny, listless, and liable to scrofulous disorders. Human beings living in dark dwellings, underneath high walls where sunlight seldom penetrates, become the parents of an unusually large proportion of dumb, blind, and idiotic children. Amongst pigs and poultry we have observed the depressing influences of dark abodes. In covered yards, shut out from the direct rays of the sun, cattle do not thrive so well as where they can bask themselves in its cheering rays. During several winters we have had under observation, in one of the midland counties of England, two contiguous yards of nearly equal size, and capable of holding comfortably eight or nine two-year old Shorthorns. The inner is entirely covered with a lofty glass and slated roof; airy, but not liable to draughts. The outer has a deep, commodious shed, continuous with the roof of the covered yard. Both yards are similarly supplied with water. Successive lots of Shorthorns during seven consecutive winters have been fed exactly alike in each yard. In both they thrive remarkably well; but the occupants of the outer yard, albeit they are further from the barn-door, invariably come out in spring with better coats and rather more condition; and this we can ascribe only to the fact that they enjoy a full share of sunshine, from which their fellows in the inner yard are almost entirely shut out.

Light, when too abundant or dazzling, is trying to the eyes. The bright glare of the sun's rays, when reflected from white cliffs, sandy flats, snow, or even from white lime-stone roads, irritates the eye, and occasionally gives rise to blindness. Some horsemen object to brightly lighted stables, on the plea that the animals are kept more upon the alert, do not compose themselves, and cannot rest well. But in a stable or kennel too much light is preferable to too little. By curtains, blinds, or other devices, any excess can easily be excluded. Deficiencies of light usually prove a cloak to filth. A dark stable is seldom clean, fresh or airy. Solid or liquid excreta are apt to accumulate, contaminating the air; dust and cobwebs escape observation; the atmosphere, if not absolutely foul is generally frouzy. Darkness being favourable to repose, a dim light is however desirable for fattening animals. Thus feeding cattle ought to be kept quiet, disturbed only at meal times, and placed in comfortable, rather dark pens. Poultry cramming for the table, for a fortnight before being finished off are cooped up in dark pens, to which light is introduced only three or four times daily at the regular hours of feeding.—*North British Agriculturist.*

DISEASE OF THE HOOF IN CATTLE.—Mr. Robert McLaren, Secretary of the South Renfrew Agricultural Society, sends the following communication:—"There are some of the cattle in this county affected with foot disease, and the people are at a loss as to the proper method of treatment. The disease appears to begin at the heel of the hind foot and follows on like a tube to the toe, where the foot begins to rot, and threatens the loss of the hoof. Any information you may be enabled to give in your next issue of the CANADA FARMER relative to the disease, and the best treatment thereof, will be thankfully received by your readers in this part.

NOTE BY ED. C. F.—The disease of the foot above referred to, is generally the result of carelessness and filth. Gravel or sand accumulates in the clefts of the hoof, which sets up considerable irritation, followed by inflammation and suppuration so that pipes form in various directions. The treatment consists in thoroughly cleansing the parts with soap and water, and also removing any detached horn, and then dress with a mild caustic, as chloride of antimony; after which the cleft should be filled with a stopping of tar and tow, which soon brings on a healthy action.

Correspondence

Crops in England.

To the Editor of THE CANADA FARMER:

SIR,—I have now been just three weeks in England, and have taken a passing glance at agricultural matters from Lincolnshire through the Midland Counties to the English Channel, which separates this country from France. As yet I have not had opportunity of examining fully any district of country, and can only furnish you with a few general remarks.

The spring here has opened earlier than usual, accompanied by a high temperature, and, consequently, notwithstanding the want of rain in some parts, all kinds of crops are forward and generally promising. Showers having recently fallen, the appearance of this picturesque and highly-cultivated district resembles a well-kept garden, which indeed is more or less the appearance of the country generally. When I left Portland on the 25th of April, there were no signs, to the casual observer, of returning vegetable life, after, perhaps, one of the coldest winters ever experienced in North America. On the twelfth day the picturesque hills of Ireland became visible; the fields being covered by a thick mantle of the richest green. The next day brought us to Liverpool, with its forests of masts; and although Lancashire is by no means distinguished for natural beauty and rural prospects, I felt deeply impressed by the loveliness of the landscape, and the forwardness of the crops. Orchards were blooming profusely, the hawthorn hedges in full leaf, and, in places, rich with flowers; while in the gardens various kinds of roses, laburnums, and numerous other flowering shrubs and plants, were in full perfection—broccoli and asparagus were actually going out of season, and cabbage (planted in autumn) well turned into head. In a few days afterwards, I found the fruit blossoms in the middle and south of England fading away, peas in full flower, and early varieties podding, some almost ready to gather. What a wonderful influence have the Gulf Stream and the insular position of the British Islands on their climate and natural productions.

Wheat, on the whole, must be considered as promising, although I saw some in Lancashire and Cheshire, apparently on wet, heavy land, wanting plant, and of a yellowish colour. Spring grain is making great progress since the rains, but the grass, in consequence of the late dry weather, is backward, compared with other crops; it is now, however, progressing, and in meadows manured and otherwise well-managed, the yield will most probably be heavy. Turnips, mangels, &c., are sown early in this country, and are now coming up. All crops are generally drilled and carefully hoed, giving a clean and nicely finished appearance. In this section of country hops are extensively cultivated, and they are unusually forward, more so, I think, than I ever saw them before. The vines, almost without exception, are exceedingly vigorous, and the management being of so careful and liberal a character, a heavy crop is being reasonably anticipated. The aphis has already made its appearance in some situations, and with it the "lady-bird," its natural enemy. A large crop would certainly be accompanied by low prices. I think that I shall be able to offer our Canadian hop-growers some useful suggestions. So strong and forward is this plant that I have already seen it, in some places, over the tops of the poles.

I have attended several markets and fairs, and had much intercourse with farmers, laborers, &c. The condition of English agriculture is, I should say, on the whole, prosperous. The cattle plague in some counties (particularly Cheshire) was very disastrous. It has now ceased, and cattle this spring are permitted to be brought to markets and fairs, as formerly. Beef and mutton, though somewhat lower, continue to maintain, for good qualities at least, high prices: from 4s 6d to 5s per stone (8 lbs), dead weight. Lean sheep meet with a very heavy sale, owing to the extremely large supply and hitherto want of grass. For several years past, especially when grain was low, a large extent of arable land was converted into pasture, thereby greatly increasing the amount of sheep and cattle. If this had not been the case, the effects of the late cattle plague would have been still greater on prices. Some farmers, I find, now that the price of wheat is high, seem inclined to put a portion of their pasturage under grain culture. A good wheat crop in Europe and America this year would so reduce prices as to remove the motive for such a change of practice. It takes many years in England, say from 10 to 25, for poor arable land to be converted into a good, permanent pasture, a change involving not only time, but a considerable pecuniary outlay, in the way of draining, seeds, and manures. The best pastures, sustaining seven or eight large sheep per acre during a large portion of the year, have been in that condition for centuries. The older it is said they are, the better; hence the reluctance manifested against ploughing them up.

I shall be in London to-morrow to see the great horse show in the Agricultural Hall, from whence I proceed to the Bath and West of England Exhibition at Falmouth, of which I hope to send you some particulars in my next.

GEO. BUCKLAND.

Tonbridge, Kent, May 29th, 1868.

NOTE BY ED. C. F.—The foregoing letter only came to hand just as we were going to press with the last number, and therefore too late for an earlier insertion.

Circular to the Agricultural Societies.

TO THE OFFICERS AND MEMBERS OF THE AGRICULTURAL SOCIETIES OF ONTARIO.

GENTLEMEN,—Permit me to remind you of the purport of a circular issued early in the year by the Hon. the Commissioner of Agriculture, having among other matters reference to the formation of an industrial museum in the Parliament Buildings at Toronto.

As the season is approaching when grains and other agricultural productions will reach maturity, I trust that the Agricultural Societies of the Province will lend all the practical aid in their power towards the realization of so interesting and important an object. It must be obvious on the least reflection that the successful carrying out of such a project must, in a great degree, depend on the cordial co-operation of our farmers and mechanics, who have been earnestly requested to furnish characteristic specimens of their various productions.

I therefore trust that, before the termination of the present year, the Department will be put in possession of such specimens of our fields, gardens, and workshops as will indicate in a creditable manner our industrial and social progress. I may just remind our agricultural friends that grain in the *straw*, whenever practicable, is very desirable.

During the short period I have been in England, the mention of this object has met with approval from several influential parties, and I hope to be able to collect material here, mostly free of cost, that will be found of much practical utility. The mere attempt to carry out an object like this is regarded here as unmistakingly indicating a desire for sound and industrial progress.

In the pleasing hope that you will give this project your hearty support, and likewise our agricultural, mechanical, and manufacturing interests generally

I remain,
Gentlemen,
Your obedient servant,
GEO. BUCKLAND,
Secy. Bureau of Agriculture, Ont.

London, May 30th, 1868.

Railway Gardens.

To the Editor of THE CANADA FARMER:

SIR,—In your issue of the 15th inst., I read with much pleasure your article on Railway Gardens, and would beg leave to state that the little oases on this railway are more numerous than your article would lead one to suppose; also, that the chief officers are very anxious that, as far as possible, their agents and employés generally should do all they can to beautify their surroundings at stations, and also help them to the extent of placing fences around, and filling in land if necessary, leaving their men to lay out and ornament, the expense of which they kindly allow them (the agents) to pay out of their pockets. The Managing Director, for one or two years, on the Toronto and Montreal District, gave an annual premium for the best laid-out and kept garden, the prize being always taken by the one at Brockville, which is really most beautifully kept, and a great credit to the persons in charge. There are also very fine gardens at Cornwall, Belleville, Newcastle, Whitby, and several other places on the Central Division, and I believe the wish is general among the agents to do all they can in this direction, but in many cases the obstacles to be overcome are great. I sincerly endorse the idea that it would be a good investment for the Company to lay out and beautify their station grounds, as they would thereby attract more travel. I have had persons assure me they have chosen the Grand Trunk Railway from Detroit east mainly to see the gardens at Kingston and Brockville; and when the train draws up at these stations a general exclamation of delight is at once manifest, and passengers rush to view them, much as I have seen tourists leave the table on a Mississippi steamer to view the celebrated Maiden's Rock. Many of these stations have fine fountains, which add so very much to their attractions that I am in hopes your excellent article may induce the Company to place them at all water stations, and especially here, and that all who can, and particularly railway men, may adorn as far as possible their waste places.

G. A. OXNARD.

ENQUIRY.—A subscriber from Addington County sends an "enquiry," which has been handed to the proper authority and will be attended to.

OIL FOR INSECTS.—A correspondent cautions all gardeners against the use of diluted coal oil as a remedy for insects. He tried the plan recommended in the *Gardener's Monthly*, and copied from that journal in our last issue, and found the application destructive to all the plants on which it was used.

SPRING-BEETLE.—Mr. A. T. Walbridge, of Whitby, sends a specimen of one of our larger spring-beetles, and wishes to know its name. The specimen sent is the *Elater* (or *Alaus*) *oculatus*. The name spring-beetle is given to the genus from their power of throwing themselves up with a jerk when laid on their back, and this species is called *oculatus* (eyed) from the eye-like spots on its thorax.

WELLS.—Mr. J. Ketchum, of Brighton, Ontario, writes:—In your issue of 15th inst., I notice an enquiry from a "Colborne correspondent" for information as to whether there is not a more economical way of obtaining water from below the ground than the old-fashioned way of digging and walling. I think there *is* decidedly a much cheaper and easier method; and in California, where I have seen the method fully tested and generally used, it gives complete satisfaction and is universally conceded to be preferable by far to the "old way." In fact it can be used, particularly for extreme depths, where water could not be obtained at all by digging. I refer to the plan of boring and piping, using 2 or 4 inch tubes. If your correspondent will address or call on me, I shall be happy to give all the information I can on the subject, with regard to tools, mode of operation, &c.

CANADIAN FLORA.—A "subscriber" asks:—Would you through your valuable columns inform me what work on Canadian plants would be best for a person intending to make a botanical collection?

ANS.—The best book for the purpose at present published is the *Manual of Botany for the Northern States of America*, by Professor Asa Gray. This work, though not intended to give the Canadian Flora, contains an account of most of our plants, and is the only work, as far as we know, that will enable the young naturalist in this country to determine the names of the plants he may meet with. A small work by the same author, entitled, "*How Plants Grow*," will be found useful for beginners, and this also contains a large portion of the Canadian Flora.

EMIGRANT'S GUIDE.—"A Constant Reader" asks: "1st. Are there any books giving reliable information as to the cost of an outfit for the backwoods, with list of necessary articles? 2nd. Is it possible for a comparative greenhorn to obtain information that will enable him to judge properly of land and timber? If so, where can he get it?"

ANS.—We do not know of any complete Emigrant's Guide for Canada; and we think that such a work by a competent hand would be of inestimable value. Our correspondent may find some information that will be of service to him in the "*Canada Emigration Gazette*," published at Quebec, which can be obtained, free of charge, from A. C. Buchanan, Esq., Chief Emigration Agent, Quebec, and probably from other Emigration Agents in this Province. There is also a small work recently published by the Rev. W. Fraser, of Kincardine, entitled the "*Emigrant's Guide, or Sketches in Canada*," which contains many useful hints. Maps of the Free Grant lands are supplied by the Crown Land Department, and information respecting them can be obtained from the same quarter. But we would caution any one who is altogether unacquainted with "land and timber" not to take up land till he has practically acquired some little knowledge of these matters by a few lessons in the "Bush," beyond the mere study of books. A year's residence with an old settler would be a good school.

The Canada Farmer.

TORONTO, CANADA, JULY 1, 1868.

American Pomology.

WE have just examined with some care, and with no little interest, the recently published proceedings of the Eleventh Session of the American Pomological Society, held at [St. Louis, in September last. This goodly volume, of 264 pages octavo, contains a vast amount of information respecting the present state of the important branch of rural industry to which it relates. The Society above-named has for its objects, adjudication of the merits of new fruits, identification of varieties, establishment of a common nomenclature, dissemination of useful pomological information, and the promotion generally of fruit-growing. It meets biennially, and its transactions consist chiefly of essays and discussions on points connected with fruit culture. On the occasion to which the report in question relates, papers were read on the general subject of pomology, on diseases of the pear, on packing and marketing fruit, on diseases of the grape, on plant diseases, and on insect enemies of fruit. Free discussion was had in reference to the subjects just enumerated, also in reference to numerous varieties of fruit; reports were also given from different parts of the United States and Canada respecting the condition and prospects of fruit-culture.

Some idea of the work done by the Society, also of the progress of pomology on this continent, may be formed by looking at the following facts: The Society's catalogue now contains the names of five hundred and sixty-one fruits, viz.: 178 apples, 122 pears, 43 cherries, 55 peaches, 6 nectarines, 11 apricots, 33 plums, 3 quinces, 18 native grapes, 22 foreign grapes, 18 currants, 13 gooseberries, 12 raspberries, 2 blackberries, and 25 strawberries. Its list of rejected varieties is even larger than its catalogue of recommended varieties, containing no fewer than six hundred and twenty-five kinds, viz.: 126 apples, 351 pears, 5 apricots, 32 cherries, 2 grapes, 31 plums, 3 raspberries, and 75 strawberries, making a total of *one thousand one hundred and eighty-six varieties of fruit*, on which the Society has put the stamp of its approval or disapproval. Each of these varieties has been the subject of free and sometimes protracted discussion, and the decision come to has been arrived at by an open vote on the part of the members who have participated in, or listened to the discussions. It is especially indicative of pomological progress, that instead of only fifty-four approved varieties of fruit, which comprised the Society's list in 1848, there are now the large number of five hundred and sixty-one. This evidence of advance is the more striking when it is considered that the standard of excellence has not been lowered but raised. The President, Hon. Marshall P. Wilder, in his opening address laid down very clearly the requisites in a tree or fruit, for obtaining favour with the Society. A good tree must possess, *first*, health, or freedom from constitutional disease; *second*, hardiness, or the power of resisting extremes of heat, cold and drought; *third*, fertility or productiveness of fruit; *fourth*, persistency of fruit, or power of adhering to the tree; *fifth*, vigour of growth, or productiveness of wood; *sixth*, persistency of foliage; and *seventh*, a good habit of growth. Those which unite these characteristics in the highest degree are most valuable. A good fruit must be, *first*, of the best quality; *second*, it must possess durability, or the property of remaining sound after being gathered; *third*, size; *fourth*, colour; *fifth*, form. It is conclusive evidence of the vast capabilities of the American continent as a fruit region, that between five and six hundred trees and fruits have stood the test of the foregoing rules, while among the still greater number of ostracised sorts there are doubtless not a few of a high order of merit, though they are eclipsed by others that are still better than they.

The Society's catalogue of approved fruits is an interesting and useful study. Certain varieties do well almost everywhere, while others have only a limited range. Thus among apples the Red Astracan, Baldwin, Early Harvest, Fall Pippin, Fameuse, Gravenstein, Yellow Bough, Maiden's Blush, Northern Spy, Rambo, Rhode Island Greening, Roxbury Russet and Wine Sap, have won golden opinions North, South, East and West. The apple has been well designated "King of Fruits." It has been also said of it that it "belts the year." A farm that has on it an orchard comprising such varieties as those just enumerated is well enough supplied with fruit, though it refused to grow any other. Pears are perhaps less cosmopolitan than apples, yet the following are spoken well of in most parts of the United States and Canada; Bartlett, Belle Lucrative, Beurre d'Anjou, Flemish Beauty, Louise Bonne de Jersey, Seckel, Tyson, Vicar of Winkfield, Winter Nelis; and he who can grow these, or the half of them, is well off. Cherries are coy, and beyond the Kentish, May Duke, and Morello, there seems to be none that can be called universal favourites. Peaches, Nectarines, and Apricots are of course limited to sunny spots and favoured latitudes. Among plums, Coe's Golden Drop, Green Gage, Imperial Gage, Lombard, Smith's Orleans, and Washington, seem to have the widest popularity, and if curculio and black knot would only let these alone, we need hardly sigh for more. Of hardy grapes there are Concord, Delaware, Hartford Prolific, and Diana, which are widely diffused and approved. There is only one universal gooseberry, the Houghton. Hovey's Seedling, Triomphe de

Gand, and Wilson's Albany, are the favourite strawberries. When you add to these varieties, which appear to do well anywhere and everywhere, those which succeed particularly well in certain localities, you have a pretty respectable collection of fruits, one of which a comparatively young country has reason to be proud and one with which it may well be content and thankful.

That much enthusiasm exists in the United States and Canada in connection with pomology there are many encouraging proofs. We link our own Dominion with the Great Republic in this remark, because the efforts of Canadian fruit growers, and especially Mr. Arnold's experiments in hybridizing, received honourable mention at the St.Louis meeting, and there seems a very pleasing disposition to work hand in hand, oblivious of national distinctions, in the promotion of fruit culture. This branch of horticulture is yet in its infancy, and although most valuable discoveries and improvements have been made, it is by no means visionary to expect that they may yet be superseded and eclipsed. Many shrewd, intelligent, experienced and persevering experimenters are at work, and we believe they will not labour in vain. Such societies as the one whose proceedings have furnished the subject of this article, are doing vast good, and deserve all encouragement. Our own Fruit Growers' Association, though more limited in its field of operations, has already laid the country under a debt of gratitude, and will doubtless in coming years increase the obligation. We sincerely wish it, and all similar associations, the success they so richly merit.

Quebec Provincial Exhibition.

It is officially announced that the Agricultural and Industrial Exhibition for "Lower Canada," as it is still called in the announcement from which we quote, will be held in Montreal in September next, during the week commencing on Monday, the 14th, that is to say, the week previous to that in which the Ontario Provincial Exhibition will be held in Hamilton. This arrangement accommodates those visitors and exhibitors who may wish to compete or be present on both occasions. A very full and liberal prize list is published, and every arrangement seems to be made with a view of rendering the exhibition worthy of the Province. Parties intending to exhibit must make their entries in the Agricultural Department on or before the 22nd of August, and in the Industrial Department not later than the 15th of September. The programme for the Exhibition week is as follows:

Monday, Sept 14th, will be devoted to the receiving of articles for exhibition, and their proper arrangement. None but officers and members of the association, judges, exhibitors, and necessary attendants will be admitted.

Tuesday, Sept. 15th. The judges will meet in the committee room at 10 a. m., and will commence their duties as soon as possible afterwards. As soon as they have made their awards, they will report to the Secretary. Admission, 50c.

Wednesday, 16th. The judges of the various classes will complete their awards, and will place all the prize tickets if possible. Admission, 25c.

Thursday, 17th. The public will be admitted this day on payment of 25cts by each person, each time of entering.

Friday 18th. *The annual meeting of the Directors of the Association will take place at 10 a.m. in the committee room.*

Saturday, 19th. The Treasurer will commence paying the premiums at 9 a. m.

All protests must be sent to the Secretary before 10 a.m. on Thursday, the 17th September.

The prize list contains some new features, among them the addition of a silver and bronze medal, to accompany the first and second prizes in the more important classes of stock. This we think a commendable example, as it supplies the successful competitor with a permanent memorial of superiority. These medals, it is announced, will be publicly distributed by his Excellency, the Governor of the Province, on Thursday, the 17th September. Another noticeable deviation from former prize lists, is in the class of horses, in which the breeds are more distinctly specified. Thus the sections are—1, Clyde; 2, Percherons; 3, Suffolk; 4, Thorough-bred Stallions; 5, Brood Mare and Foal; 6, Heavy Draught Stallion, (1300 lbs and over); 7, Middle Draught Stallion, weighing 1200 lbs. and over; 8, Light Draught Stallion, weighing 900 lbs and over; 9, Three year old Stallion of any breed; 10, Brood Mare and Foal, Heavy Draught; 11, Brood Mare and Foal, Light Draught; 12, Three year old Filly, any Breed; 13, Pair of Draught Horses; 14, Pair of matched Carriage Horses; 15, Saddle Horses. We expect the above classification will be open to some criticism amongst horse fanciers, and will elicit considerable differences of opinion.

The industrial building will be fitted up for the reception of the industrial department, as in 1865. The skating rink will receive the Horticultural Department, under the special care of the Montreal Horticultural Society. The ground selected for the cattle sheds are the same as last exhibition. The usual half fare arrangements have been secured from the various railroad and steamboat companies.

Illinois State Fair.

The Illinois State Fair is to be held the present year from Sept. 21st to 26th, at Quincy, the same place as last year, one of the most beautiful and thriving cities in the Mississippi valley. The grounds and fixtures used last year were found very commodious and convenient. It is intended to enlarge and improve the accommodation, so as to afford every facility possible for intending exhibitors. Large additions have recently been made to the hotel capacity of Quincy, and it is considered that no place in the West, of its size, is better prepared to entertain a large number of visitors. There are two features in the coming Illinois Exhibition which we note with much pleasure. The first is, the prohibition of horse racing, and all its concomitants. Concerning this great and growing evil in connection with Agricultural Fairs in the United States, the Executive Board of the Illinois State Agricultural Society have taken most praiseworthy action, and we hope their example will be extensively copied. Let the New England Society, especially, blush at the idea of being outdone in moral excellence by the Prairie State. We quote from the Circular announcing the Exhibition of 1868, so much as refers to this matter, deeming it a capital epitome of the reasons why such a stand should be taken universally:

"The Executive Board, in obedience to their own convictions, have resolved to permit, as part of the exhibition, nothing having a tendency to lower the proper moral standard of Agricultural Fairs; and they are expressly determined to exclude from the grounds horse-racing and its usual accompaniments, jockeyism and gambling. Let their position not be misapprehended. This action is dictated not by any feeling adverse to the horse interest, the importance of which they well understand and are glad to acknowledge, but by a just regard to the legitimate aims of agricultural fairs, as well as to deliver the interest itself from the injury inflicted upon it by a certain professional class, who, claiming to be its especial champions, are its worst enemies. The legitimate breeder of horses of every class will find in the list of premiums unusual encouragement, and in the discretion given to committees, ample opportunity for the display of action, and other tests of the valuable qualities of his favorites; but those GIPSIES OF THE TURF "*who prowl about*" *the Race Course and County Fair speed-rings "for human prey,*" are not expected to participate as exhibitors. Having taken this position, the Board expect to be sustained in it by all good citizens who feel an interest in the true progress of agriculture and industry, and particularly by those whose specialty is rearing good, serviceable horses."

Another noteworthy feature in the Illinois arrangements, is the provision of suitable camping-ground, for those who prefer that economical and independent mode of self-entertainment during the fair. The expense of hotel accommodation, and the certain discomfort consequent on the crowded state of the hotels, are considerations that deter many from attending Exhibitions who would otherwise do so. At a season of the year when the weather is enjoyable, and the nights are warm, there is no danger to health in camping out, and if proper arrangements and regulations are made, we see not why the provision would not tend to secure both a larger and longer attendance on such occasions. Complaint has been made in connection with our own Provincial Fairs that horse boxes and cattle stalls have been occupied as bed-rooms and boarding-houses, to the exclusion of their legitimate occupants. What has been done irregularly and stealthily, might, we think, be advantageously done under official sanction and superintendence. In fact, we see no reason why a range of sheds might not be put up under the direction of the Board, and apartments let during the Fair at a moderate rental. It requires a considerable outlay to pay travelling, hotel, ticket, and other expenses at such times. Our backwoods farmers especially, who are not flush of money, but who, more than any other class, would be benefited by attendance at the Provincial Exhibition, would be allured by such an arrangement. They are accustomed to rough it in the bush, and would think nothing of camping out for two or three nights, if facilities were afforded for their doing so. We commend this feature in the Illinois arrangements to the attention of those with whom it rests to make preparation for our own approaching Exhibition.

The Season.

As elsewhere chronicled, in our article on the month, we have pleasure in putting on record that the season continues to be one of the most favourable within the recollection of that sapient and venerable individual "the oldest inhabitant," and that all the accounts which reach us from various parts in reference to the crops are of the most satisfactory nature. So far everything augurs well for a year of plenty, and consequently a year of prosperity.

NEW YORK AGRICULTURAL EXHIBITION.—The New York State Fair will be held in the week commencing Sept. 29th, not 19th, as by a typographical error was stated in our last.

ROBERTS' HAY ELEVATOR.—An advertisement of this Hay elevator appeared in our last issue, but was not sent in time for any editorial notice. We now draw attention to the new implement which, from a personal examination and testimony in its favour, we believe to be at once simple and efficient. It is manufactured by T. Wrong & Co., 70, Bay Street, Toronto. The price of the elevator, with pulleys and rope complete, is $10.

Worthen and Baker's Hand-Loom.

We direct attention to an advertisement in our present issue, of this very useful domestic machine, which we have had an opportunity of examining and seeing at work at Mr. Norris Black's in this city. It is neatly furnished, occupies comparatively little room, appears to be very easily operated, and to turn out good work. Such a machine would be invaluable to many of those who reside at a distance from large towns; and, indeed, almost any farmer in whose household the female members have any leisure would find it advantageous to possess one of these looms. We all know that the quality of home-made goods is genuine, and, as a rule, far superior in strength and durability to any that can be bought. The manufacturers thus speak in reference to the capabilities of the machine:

"The simplicity of this machine, and the speed and accuracy with which it performs all the work of making cloth, is admired by all who see it operate.

"It lets off the warp, winds up the cloth, throws the shuttle, and treads the treadles by simply turning an easy crank. When the warp is drawn through the reed and harness, on the same warp, Jeans, Satinett, Tweed, Linsey, Blanket Twill, Double Plain, Fencing Twills, and various kinds of Ribbed Goods and Balmoral Skirting can be woven. To make the changes from one kind of Cloth or Twill to another, requires but two minutes, and they are so easy and simple that a child can make them after one time showing. The improved Loom also weaves Flannel, Cassimeres, Flax and Tow, Linen Bagging, and all Wool, Hemp, and Rag Carpeting. Warping and beaming is done in the same way as per the old-fashioned Hand Loom, and every provision is made on the Loom to facilitate the beaming of work."

Multiplying Seedlings.

To the Editor of THE CANADA FARMER:

SIR,—One sometimes conceives a good idea, but neglecting to put it in practice, so as to communicate it, it is lost. Mine came too late to put in practice this spring, but unwilling that my flower should "blush unseen," I take the first opportunity of giving it to the world.

Everybody conversant with fruit-raising is aware that good fruit trees are raised from seed, in fact that our best varieties originate in no other way; but the proportion of good seedlings is so small, it is so long waiting for them to bear, and the whole expense and trouble of bringing them out so great, that any plan of lessening the expense and time will be considered important.

My plan is this: take cuttings from such seedlings as may be considered worth testing, and graft or bud them upon the previous year's wood, of a healthy grown tree. In this way an immense number of scions could be put on one tree, and nearly every orchard has one or more suitable trees, which do but little in the way of bearing fruit. I am of opinion that the wood of a young plant grafted into a tree of mature growth, would bear as soon as a scion from the old tree. I may be wrong; the thing has not been tried yet; but if it succeeds as well as I expect, what an immense number of apple, pear, and other seedlings can be put on trial at a very small outlay of time or money. I hope some of your readers who have a desire to benefit themselves and the fruit-eating community by developing new fruits, will give my plan a trial, and I would just remind them that the budding season is not very far off, and may be taken advantage of for the purpose.

TENDEAU L'ARRADEE.

Asparagus in France.

THIS is one of the leading vegetables in France. The following, from the London *Journal of Horticulture*, shows how careful they are in selecting seed:

"Every grower raises his own roots by sowing selected seed. The largest and earliest ripened seeds are chosen. A bed of sandy, unmanured soil is lined off, forming little furrows twelve inches apart, and the selected seed finger-and-thumbed-in at least four inches apart. After the rake has been drawn over all, the seed will be two inches from the surface. This operation is done on a dry day in February. By the end of March, a hoeing before the seeds germinate tends to keep the seed beds clear of weeds, after which the young plants soon begin to show themselves above ground. The end of April and the beginning of May bring hot, dry weather. A slight mulching with decayed manure is now applied. After this nothing more is required but a little hand weeding and repeated waterings in very hot weather throughout the year. At the period when they may be termed yearlings, with half an inch of growth, which will be about the end of March, is the time when the planting in the *Aspergerie* takes place.

How to Make Gravel Walks.

In the first place remove all the soil and vegetable mould, where the walk is to be made, to the depth of six or more inches, so that there will be nothing to promote the growth of grass roots. If this precaution is not taken, grass roots will soon spread from the sides of the walk, and grass will cover the entire foot path. After the way has been evacuated to the desired depth, let the depression be filled with coarse gravel, if it can be obtained, and the surface covered with clean, small gravel, about one or two inches in depth. Then roll the surface with a heavy roller. If any stray spears of grass should appear in the walk, let them be pulled up at once. A more effectual way, however, is to sprinkle salt over the walk, or apply a weak brine with a watering pot. A weak brine will effectually destroy all vegetation in a walk, at an expense of only a few dimes on the salt.

Another way to form the body of a walk is to fill the excavation with blacksmith's and iron founder's cinders, or pieces of old brick, old mortar, lime siftings, oyster and clam shells, or anything else of a similar character. Then cover the surface with about two inches of sharp, clean gravel, that is free from mould, or anything that will promote the growth of vegetation. If gravel must necessarily be carted a long distance, the surface of rubbish may be covered with only a thin coat of clean gravel. Let it be borne in mind that one barrel of salt sowed over the walk, will save much labor and expense in keeping down weeds and grass. This is a very cheap and satisfactory manner of making a loose or open gravel walk. Where the soil is heavy, and there is only a thin stratum of mould on the surface, resting on a compact subsoil, in which there is little or no vegetable matter, nothing but the thin stratum of mould need be removed, where a walk or carriage drive is to be made.—*N. Y. Times.*

Tree Mignonette.

Sow a pinch of seed in the centre of as many three inch pots as there are plants required. When the young plants are strong enough thin them by degrees to one plant in a pot, and that must be the strongest. Train that up a stake to the height required, pinch out all side shoots and the heads of bloom, but do not divest the stem of its leaves until the plant has attained its full height. To form a head leave about three shoots at the top, and pinch them in from time to time.

I have had tree Mignonette four and five feet high, with heads two feet through, by sowing the seed, as above described, in August, and growing the plants for twelve months, shifting into larger pots when required. These were handsome objects in the conservatory, and afforded many cut flowers all winter. For ordinary sized trees the seed should be sown during the first week in May, to bloom throughout the following winter. Different catalogues announce a giant variety for this purpose, but in growing the two I have found no difference.—THOS. RECORD, *Hawkhurst, in London Journal of Horticulture.*

TRANSPLANTING CABBAGES.—The *Gardener's Monthly* recommends the following mode for enriching the soil for young cabbage plants just before they are set out, for the purpose of giving them an early and vigorous start. Make holes with a dibble where the plants are to be set, and then fill these holes with manure water. It soaks away into the surrounding earth, and becomes perfectly diffused through it. The plants are then set in the holes.

TRANSPLANTING IN THE NIGHT.—A gentleman anxious to ascertain the effect of transplanting at night, instead of in the day, made an experiment with the following result: He transplanted ten cherry trees while in bloom, commencing at four o'clock in the afternoon, and transplanting one each hour, until one in the morning. Those transplanted during daylight shed their blossoms, producing little or no fruit; while those planted during the darker portions maintained their condition fully. He did the same with ten dwarf pear trees, after the fruit was one-third grown. Those transplanted during the day shed their fruit; those transplanted during the night perfected their crop, and showed no injury from having been removed. With each of these trees he removed some earth with the roots. The incident is fully vouched for; and, if a few more similar experiments produce the same result, it will be a strong argument to horticulturists, gardeners, and fruit-growers to do such work entirely at night.

THE USE OF FLOWERS.—Says a writer in *Harper's Weekly*:—There has been of late years a marked increase in the use of flowers for social purposes. Every dinner party or dancing party must now be graced with these "stars of the earth." At larger assemblies there is always a lavish display of flowers, as if it were designed to intoxicate the guests with the delicious odors of innumerable blossoms. If we visit a lady, flowers must precede our coming; if we drive out with her, the odor of flowers must sweeten the pleasure. Superb presentation baskets and bouquets are now seen in almost every parlor, and are the horticultural compliments of gentlemen to ladies. The favorite flowers are the camellia japonica, the sweet Neapolitan violet, and the white and tea rose. Although a large capital is employed in producing these, the supply is always unequal to the demand, and they bring high, even extravagant prices, on great occasions. Flowers are of course extensively used at weddings, but according to the florists, they are employed more liberally at funerals. Five hundred dollars are not unfrequently expended in crosses and wreaths for these solemn occasions.

Agricultural Intelligence.

An Agricultural Degree.

We are glad to learn from our British Exchanges that the University of Edinburgh intends to confer the Degrees of Bachelor and Master of Agriculture ("Agr. B." and "Agr. M.") on all who may be found worthy of such distinctions. Before any candidate can graduate in agriculture, he must satisfy the examiners as to his general attainments by undergoing a preparatory examination, unless that be rendered needless by the possession of certain specified certificates of qualification. The following is the published programme:

"The candidate who has passed successfully this examination may present himself at the next examination for his degree of Bachelor of Agriculture. For this examination the candidate must produce certificates of acquaintance with practical agriculture, and is required, with the view of specializing his studies, to profess one, and not more than one, of the following groups of subjects, with their practical relations to agriculture:—A. Natural Sciences—Botany, Geology and Zoology; B. Experimental Science—Chemistry and Physics; C. Mechanical Science—Mechanics and Engineering. The certificates of the Royal Agricultural Society, the Highland Society, and the Royal Agricultural College will be accepted for practical agriculture.

"Successful candidates who have thus acquired the Degree of Agr. B. may at the next period of examination, provided they have attained the age of 21, proceed to the examination for the Degree of Master of Agriculture (Agr. M.). For this Degree the candidate will be required to submit to a searching examination on one of the following subjects, in its special relation to agriculture:—A. Agricultural Chemistry—organic and inorganic:—B. Agricultural Mechanics—Machinery and Implements; C. Engineering (Civil) Surveying and Draining, &c.; D. Natural History—Botany, Geology, &c.; E. Animal Physiology—breeding, rearing, &c., of animals. The examinations for Degrees will be conducted by University examiners, and an examiner appointed by the Highland Society."

Agricultural Societies & Officers for 1868.

We publish in the present issue, as we did in the corresponding issue of last year, a list of the Agricultural Societies and officers for the current year, so far as returns have been made. Omissions, where they occur, must be attributed to the fact of no return having been sent in. Where blanks appear under the column headed Treasurers, it is to be understood that the office is held in connection with the Secretaryship. As soon as the new law comes fully into operation, it is expected that a more regular system will be adopted, and one which will enable us to give a still more complete and an earlier list.

☞ The canker worms have begun their depredations in the neighbourhood of Newton and Auburndale, Mass., and the foliage of the trees is rapidly changing to a rusty red.

☞ A new variety of corn, the result of selecting seed and of high culture, has originated in Minnesota. The yield last year was as high as one hundred and thirty-seven bushels to the acre.

FALL EXHIBITION.—The annual Exhibition of the South Simcoe Electoral Division Agricultural Society will be held at Bradford on Thursday and Friday, Oct. 1st and 2nd.

ARMY WORM.—The Corinth, Miss., *Model. Farmer* for May, says the army worm is on the march there in amazing force. The *Farmer* makes the following astounding statement: "The movements and numbers of this insect are astounding. The army worm has appeared in this country near the State line, and is now moving southward. Their breadth is about two miles, and they are stripping the forest of all foliage in their path. There are so many millions, that last week they actually stopped the freight train on the Memphis and Charleston Railroad. The worms were so thick on the track that they accumulated on the wheels until it caused the drivers to slide on the rails. We don't think this is the regular army worm, but a species of insect smaller, and not so destructive to vegetation."

AGRICULTURAL AND HORTICULTURAL SOCIETIES AND OFFICERS, 1868.

NOTE.—Towns distinguished by an asterisk (*) have organized Horticultural Societies, under Section 26 of the Statute.

Entomology.

The Wheat Midge.

SHORTLY before the issue of our last number, but too late for insertion in it, we received the following communication from Mr. Alex. J. Belch, Proprietor of the *St. Mary's Argus*. It was accompanied by a lump of clay containing an enormous number of small orange-yellow larvæ:—

(MR. BELCH'S LETTER.)

"A farmer of Blanshard has just handed me the enclosed lump of mud, containing the 'rare things' you notice in it, and which he and his brother farmers pronounce 'the weevil.' The handful was scraped up from a field in which was fall-wheat last year, and which contains wheat this year. The whole field is covered with these insects, discovered just after the late heavy rain, but none can be found on meadow land or in fields sown to peas and other grain last year. It is the opinion of farmers hereabout that the insects remain in the land all winter, from the fact that they are too far advanced in growth to be the product of the egg deposited by the fly this year. They are not found on land unaffected by weevil last year, nor upon land sown to other crops last year, or upon meadow land.

"Of course all depends upon whether the insects really are the weevil or something resembling it. I may say that all intelligent, observing farmers in this section, to whom the clay was shown, unhesitatingly pronounce it the weevil, and they feel so interested in the matter that I have thought it would be well to let you see a specimen, and ask you to ventilate the subject by enquiring through the CANADA FARMER whether the same deposit has been observed in other sections of the country. The investigation might possibly throw some clearer light upon the origin of that farmers' scourge, the weevil, than already exists."

We have given a very close and careful examination to a large number of the specimens contained in the portion of earth sent us, and can now state positively that the orange-yellow larvæ or maggots are the larvæ of the well-known wheat-midge (*Cecidomyia tritici*), an insect commonly, but erroneously, called "the weevil." To render us the more certain of the identity of the insect, there issued from the loose wrappings round the lump of earth, a single winged specimen which we had no difficulty in determining to be a male wheat-midge; the sex is remarkable, as, in general, myriads of females may be taken in the fields they infest, while a male is very rarely found.

With regard to the occurrence of these larvæ in the ground early in June, it is only what we should naturally expect, for, as we stated in an article on the 1st of May last, a large proportion of the larvæ descend into the ground to undergo their transformations, while some remain permanently in the ear. The specimens before us, in all probability, entered the earth last year before the crop was removed from the field, and there remained till the spring; the heavy rain referred to by our correspondent, quickened them into activity, and caused them to approach the surface of the earth; then the pupa state is assumed for a short time, from which they emerge in the form of winged flies, usually in the month of June, ready to lay their eggs in the blossoms of the new crop of wheat. We fear that the farmer from whose land were brought the specimens before us will obtain but a scanty crop of wheat this year, if the whole field is even half as thickly infested with the insect as the portion of earth sent to us. It is a great pity that wheat was again sown in the same field; the best plan would have been to have ploughed under the surface soil as deeply as possible, and then have grown upon it a totally different crop; the majority of the insects would thus have been either prevented from coming to maturity, or so much retarded as to be unable to do much injury.

The effect of moisture upon these insects is very remarkable. During our examination of them, we took a few dry, motionless specimens, and laid them upon a piece of glass, where they remained perfectly still; then we dropped a little water upon them, and almost immediately they began to move about, crawling over the surface of the glass as long as the water surrounded them; after a time the drop evaporated, and very soon they became as stiff and motionless as before. This experiment we repeated several times, and always with the same result. Dr. Fitch has also observed somewhat similar effects, so much so, that he speaks in one place of the larva as being amphibious in its nature.

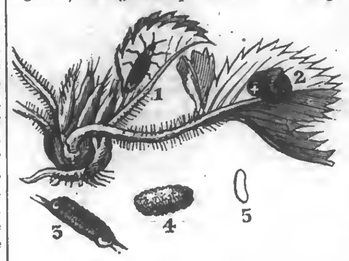
We shall be glad to learn from our correspondent what is the condition, from time to time, of the wheat field from which this earth was taken; we shall also be especially anxious to hear how the crop turns out, and whether the midge proves troublesome in the neighbourhood. It is only by gathering together information from different localities, and under different conditions and circumstances, that we can ever expect to understand completely the life history of our insect enemies; and to know thoroughly their nature and habits is the greatest help of all towards finding out an effectual remedy.

The Strawberry Worm.

(*Emphytus maculatus.*)

As this delicious fruit is now so universally cultivated, it is well for us to be acquainted with its enemies, that they may be prevented from such undue multiplication as to become a universal curse.

There are two caterpillars which, by their very destructive attacks on this plant, have of late years attracted attention in the West. One of them is a true caterpillar—the larva of a moth—rather more than one and a half inches long, of a pea-green color, smallest at the first, and largest at the last segment; curling itself up in a ball and falling to the ground whenever the plant is touched. The other is a false caterpillar—the larva of a four-winged fly—much smaller, but more destructive, and it is the history of this last that I will now elucidate.



This insect is, in all probability, quite generally distributed throughout the West, as it occurs in the southern portion of this State, and I have found it in this county. Complaints of its ravages have also been sent me from Berrien County, Mich., and Mr. W. H. Castor, of Niles, had great difficulty with them last year.

In the month of May, in this latitude, numerous flies may be seen hanging to, and flying about the vines, in fields which have been previously infested. They are dull and inactive in the cool of the morning and evening, and at these hours are seldom noticed. They are of a pitchy black color, with two rows of large transverse dull whitish spots upon the abdomen. The female, with the saw-like instrument peculiar to the insects of this family, deposits her eggs, by a most curious and interesting process, in the stems of the plant, clinging the while to the hairy substance with which these stems are covered. The eggs are white, opaque, and 0.03 of an inch long, and may be readily perceived upon splitting the stalk, though the outside orifice at which they were introduced is scarcely visible. They soon increase somewhat in bulk, causing a swelling of the stalk, and hatch in two weeks—more or less according to the temperature—and by the middle of May (speaking of Northern Illinois) the worms attract attention by the innumerable small holes which they make in the leaves. Their colors are dirty yellow and gray-green, and when not feeding they rest on the under side of the leaf, curled up in a spiral manner, the tail occupying the centre, and fall to the ground at the slightest disturbance. After changing their skin four times they become full-grown, when they measure about ¾ of an inch.

At this season they descend into the ground, and form a very weak cocoon of earth, the inside being made smooth by a sort of gum. In this they soon change to pupæ or nymphs, from which are produced a second brood of flies by the end of June and beginning of July. Under the influence of July weather, the whole process of egg-depositing, etc., is rapidly repeated, and the second brood of worms descend into the earth during the fore part of August, and form their cocoons, in which they remain in the caterpillar state through the fall, winter and early spring months, till the middle of April following, when they become pupæ and flies again, as related.

The accompanying illustrations represent the insect in various stages: fig. 1, showing the perfect fly, natural size; fig. 2, the larva at rest; fig. 3, the larva crawling; fig. 4, the cocoon; and fig. 5, the egg enlarged.

And now, knowing the facts in the case, it will be no difficult matter for any one interested to make war in his own way. Their habit of falling to the ground enables us to destroy them with coal oil, or any other decoction, without sprinkling the vines; while, knowing that they are in the earth during the fall and early spring, when there is no fruit, the ground may be stirred and poultry turned in with good advantage.

This insect belongs to the order HYMENOPTERA, the family *Tenthredinidæ*, the genus, *Emphytus*, and as I learn from Mr. Walsh was named *maculatus* by Norton, in consideration, no doubt, of the spots above referred to.—*C. V. Riley, Prairie Farmer.*

The Black Currant Caterpillar.

To the Editor of THE CANADA FARMER:

SIR,—For the first time during the life of, or rather during the time the writer has been able to observe anything, the black currant has become affected with a worm or devourer apparently peculiar to itself. The first time it was observed was last summer, 1867, when suddenly the whole of a long row of black currant bushes became covered with innumerable light-coloured moths. There were a few worms followed, but not many, and some holes were eaten in the leaves; but the worms were very hard to find, and they did not come at all in proportion to the number of the moths.

The moths were white and ash-coloured, feathery and soft, with small black spots on the wings. They were very active and busy during the day, more so than in the evening, although they appeared in the evening also. There appeared to be so little difference between the males and the females that they could not be distinguished, and we could not trace any eggs on the leaves. This year, however, 1868, on the 13th June the worms first showed themselves, and they bid fair to strip the trees.

The worm is light in colour, white crash-coloured, with longitudinal yellow stripes down the back, with black spots; the back whiter than the side. It is a "measurer," and moves the hinder parts close up to the fore set of legs, arching its back and bringing the extremities together. The skin of the worm is not hairy. It is very active; it is a spinner also, and when disturbed throws itself down, holding on to a short web which exudes from the mouth, similar to the worm which at times devastates the oak forests in England; indeed, both worm and moth are very similar to the oak worm and moth, but it does not spin so long a thread.

Samples of the worm are enclosed herewith for the entomologist to pass judgment on and to name, and the moths all besent when it appears.

It is a curious fact that these plagues to different kinds of trees and plants make their advent, continue for a few years, and then nearly or quite die off. The Locust or accacia borer, has now ceased to work in destructive numbers, and all the locust trees are recovering, being able to grow faster than the borer can injure them. No doubt all these insects are governed by the same laws, and in time bring their own parasites with them, which reduce their numbers below the destructive point.

C.

Toronto, 18 June, 1868.

NOTE BY ED. C. F.—The caterpillars sent are specimens of the larvæ of the well-known currant moth (*Abraxas? ribearia*, Fitch), of which a full account has been given in former numbers of this journal (see CANADA FARMER, 1865, p. 231; and 1867, p. 202, for description and remedies.) It is only during the present and last seasons that we have found these caterpillars on the black currant bushes; formerly they confined themselves to the white and red varieties and gooseberry bushes. The moth, we should say, can hardly be called *white*, it is rather pale buff or nankeen yellow, with black spots. We are glad to hear that the ravages of the locust-tree borer (*clytus flexuosus*) are beginning to subside; probably a parasite affects it; should our correspondent find that such is the case, we should be glad to hear further from him.

The Palmer Worm.

A correspondent from the neighbourhood of Kingston, sends the following hint:—"The Palmer worm is very numerous in this locality. Yesterday I called the attention of a person seventy-seven years of age to the fact; he immediately got a ladder and cleared the tree of the pest. If it was of so much importance to him at his time of life, surely it must be equally so to the community at large."

We are not quite sure whether our correspondent means, by "the Palmer Worm," the insect usually called by that name in the New England States, or the common Tent Caterpillar. The former we have never met with in this country, though, of course, it is not at all unlikely that it should be found in Canada; the latter is but too well known throughout the length and breadth of our land. However, no matter which insect it is, the duty of fruit-growers remains the same—to destroy it utterly whenever and wherever seen. The tent-caterpillar had better be destroyed at night or on rainy days, when all the inhabitants of a web are at home; this can easily be done either by cutting off the branch and burning it, or by tying some rags to the end of a pole, and with it rubbing off the whole nest, burning or stamping on all its inhabitants.

The habits of the Palmer-worm are different, and are thus described by Dr. Fitch:—"Appearing the latter part of June, at times excessively numerous, residing in worm-eaten leaves drawn together by silken threads, and when jarred, dropping and hanging in the air suspended by a thread: a pale, yellowish-green worm, having a dusky or blackish stripe along each side of the back, edged on its upper side by a narrower whitish stripe, and with a dusky line on the middle of the back. The pupa remaining in the same mass of leaves occupied by the worm, and giving out the moth in about ten days. The moth ash-grey, with its fore-wings sprinkled with black atoms, and having four black dots near the middle and six or seven smaller ones around their hind edge." He recommends, as a mode of destroying them, "attaching a long, stiff handle to an old tin pan, smearing the inside of the pan with tar, bird-lime, or some similar adhesive substance, and catching the worms in this by swinging it around under the tree as they hang suspended—renewing the coating as often as it becomes so covered with the worms and their threads as no longer to adhere to them."

The Apiary.

Why do Bees Refuse to stay in a Hive?

BEEKEEPERS often experience great difficulty in getting a swarm of bees to stay in a hive. Not unfrequently a few hours, and sometimes even a day or two, after a swarm has been hived, it suddenly swarms out, and either goes to the woods, or clusters again as at first. There are various reasons given for their doing so, many of which, however, are not correct. It is said by some that if a nail appears on the inside of the hive, or if the hive is planed on the inside, the bees will not stay in it. Others again affirm that bees will not stay in a painted hive, because they do not like the smell of the paint, and many other equally absurd notions are entertained by some few bee-keepers. Such reasons, however, are but the flickering rays of superstition, fast fading out before our rapidly increasing knowledge in the science of bee-culture. The principal cause of bees leaving a hive after having been newly put into it is, too great heat. When a swarm of bees are cast, they rush from the hive under great excitement, causing much animal heat. They are then, not unfrequently, put into a hive which has been standing exposed to the sun, and are then left with the rays of the sun still falling upon the hive. The consequence is, the heat becomes so great in the hive that they are compelled to leave. If the hive is new or recently painted, the heat will of course be greater. Care should be taken to keep the hive well shaded, and if the weather is excessively hot it is well to wet the hive with cold water two or three times a day for two or three days. Bees will sometimes leave from other causes, such as being hived without a queen, the queen being lost or killed; or if they had found a home in some hollow tree before they swarmed they may prefer it to the hive, and accordingly leave and go to it. Such instances, however, are rare, and the more frequent cause, as before said, is excessive heat in the hive.

BEE BATTLES.—In almost every work on bees you find accounts of bee-battles; but in no one of them (at least so far as I have seen) do you find any attempt to explain the causes of them. Now, any one who has observed bees at all, will readily agree with me that they are far too *sensible* to engage in *causeless* war, and I am surprised that some one has not, before this, found out that it has been caused by *starvation*. In every instance of it which has come under my observation, (and I am sorry to say they are not a few,) it has been the effect of want of stores. The starving bees attempting to join, and strong stocks who make violent resistance to the union, and thus ensues desperate war.—Cor. in *Bee Journal*.

First Prize Cheese Vats!

TO THE DAIRYMEN OF CANADA.

THE UNDERSIGNED keeps constantly on hand the following articles: Cheese Vats and Heaters of all sizes and styles. Red Cherry Press Hoops and Followers, (turned). Screws of all sizes and patterns. Carrying Cans and Dairy Pails, of the best material. Bleached cotton Bandage Cloth, imported expressly for the trade; and everything required in the manufacture of Cheese

AT LOWEST REMUNERATIVE PRICES.

☞ My Vats took First Prize and Diploma at last Provincial Exhibition.

v5-10-1f. Address H. PEDLAR, Box 100 Oshawa, Ontario.

MILLER'S

INFALLIBLE

TICK DESTROYER FOR SHEEP!

DESTROYS the TICKS; cleanses the skin; strengthens and promotes the growth of the wool, and improves the condition of the animal.

It is put up in boxes at 35c., 70c., and $1, with full directions on each package. A 35c box will clean twenty sheep.

HUGH MILLER & Co., Medical Hall, Toronto.

187 King Street East. v4-14-1f

LAMB KNITTING MACHINE

Price Reduced to 58 Dollars.

IT sets up its own work, knits all sizes, narrows and widens, knits the heel into the stocking, and narrows off the toe complete—producing all varieties of knit goods. It is *simple, durable, easily-operated*, and guaranteed to succeed in the hands of *every purchaser*. Send Stamp for Circular and sample stocking.

JAMES D. ORNE, *Gen. Agent.*

v5-8—tf. 176 State Street, Rochester, N. Y.

SMALL CHEESE VATS!

H. PEDLAR, Manufacturer, will send to any Railway Station in the Province of Ontario, (free of charges,) a first-class Cheese Vat, all complete, in running order, suitable for twenty to thirty Cows, on receipt of $30.

☞ All work warranted to give satisfaction.

v5-10-1f. Address H. PEDLAR, Box 100, Oshawa, Ont.

JONES & FAULKNER,

(Late J. JONES & Co.)

Dairymen's Furnishing Store!

—AND—

DEALERS IN BUTTER AND CHEESE,

No. 141 Genesee Street, Utica, N. Y.

DAIRY necessaries of every description always on hand, particularly **Pure Annatto**, an article in much request among dairymen.

No Duty on Annatto purchased in the United States.

☞ Special attention given to Canadian orders. v4-19-1f

TO FLAX GROWERS.

THE undersigned will have, the present season, a supply of FLAX-PULLING MACHINES, which we can guarantee to do good work, having been fully tested last season. New improvements added this year. Send for cut of Machine and Price List.

OSWOLD & PATERSON,

1st May, 1868. Woodstock Iron Works. v5-9-6t.

GEO. A. DEITZ,

The Great Seed Wheat Grower,

CHAMBERSBURG, Pa., sends free a Descriptive List of the best Seed Wheats in the world. v5-11-6t

Duncan's Improved Hay Elevator.

PATENTED April 13th, 1867.

THE cheapest and simplest constructed Fork in use in the Dominion of Canada. County or Township Rights for the manufacture of the above Fork may be obtained from the undersigned.

JAMES W. MANN,

v4-20-1f Port Dover, Ont.

J. H. THOMAS'

FIRST PRIZE BEE HIVES!

Persons desirous of purchasing territorial rights for my Hives, would do well to apply at once, as I will sell for the next two months, Townships at from $20 to $30, and Counties from $50 to $150.

J. H. THOMAS, Brooklin, Ontario.

N.B.—Parties residing in the Counties of Carleton, Russell, Ottawa, Pontiac, Renfrew, Lanark, Leeds, Dundas, Stormont, Glengarry and Prescott, and desiring to purchase my hives, must in all cases address their orders to JOHN HENDERSON, New Edinburgh, Ont.

ITALIAN QUEENS.

HAVING made arrangements for BREEDING a large number of Italian Queens, I will be able to fill all orders for the same, guaranteeing their purity and safe arrival by express. Have obtained two very fine Queens through Mr. Gray, of Ohio, for breeding purposes, and therefore prepared to furnish Queens of a bright color, and producing fine workers. **Price $5 Each.**

Bee keepers would do well to send their orders at once.

J. H. THOMAS.

THE BEST SHEEP MARK YET INVENTED.

IT is made of tinned wire stamped with name and number. Is cheap, does not wear out, and looks well. Price three cents each.

ARCHIBALD YOUNG, Jr., Sarnia, Ont.

☞ N. B.—AGENTS WANTED. v5-13-tf.-o.s.t.

SHARPE'S

IMPROVED SWEDE!

NOW READY FOR SENDING OUT.

WE beg to announce to our customers that our SHARPE'S IMPROVED PURPLE TOP SWEDE can be sent forward on receipt of order, and that we are prepared to supply them in full. Our reason for curtailing their orders last season was in consequence of a very short quantity we were able to obtain. We are, however, pleased to state that we are able to surmount this difficulty this season, having made our purchases somewhat in accordance with the requirements of previous years, and consequently will endeavor to fill all orders entrusted to us.

This superior Swede has gained a world-wide reputation and far surpasses any other variety, both for quality and quantity, yet introduced. We also have the following varieties of Swede:

SHARPE'S IMPROVED SWEDE.	
SKERRING'S	DO.
MATSON'S	DO.
MARSHALL'S	DO.
SUTTON'S CHAMPION	DO.
EAST LOTHIAN	DO.
ASHCROFT'S	DO.

ALSO,—White and Yellow Fleshed Turnip Seeds in every variety.

☞ Parcels of over ten pounds DELIVERED FREE to any part of Canada.

Paxton, Tate & Co., Port Perry, Ont.,

MANUFACTURERS OF THE

MARSH HARVESTER!

AGRICULTURAL IMPLEMENTS

OF ALL KINDS,

STAVE & SHINGLE MACHINERY,
OSCILLATING MULLEY SAWS,
TURBINE WATER WHEELS,
MILL CASTINGS, etc., etc.,

MADE TO ORDER.

☞ *Repairing of all kinds promptly attended to.* ☜

WARRANTY.

We warrant the Marsh Harvester to be well made, of good material, and when properly used, not liable to get out of repair; to be a good grain-cutting machine upon which two experienced binders can bind in average grain, on suitable ground, from eight to twelve acres in twelve hours; and that it will work on as rough ground as any other Reaper

PAXTON TATE & CO.

Port Perry, March 28, 1868. v5-7-tf

FRUIT GROWERS' MEETING!

THE SUMMER MEETING OF THE

ONTARIO FRUIT GROWERS' ASSOCIATION

WILL BE HELD IN THE

AGRICULTURAL HALL, TORONTO,

On Wednesday, July 8, at 11 o'clock, a.m.

WORTHEN AND BAKER'S

HAND-LOOM

WEAVES all kinds of Cloth with either Woollen or Cotton Warp. It is all worked by turning an easy crank. Farmers would get better clothes if they would make up their own wool, especially now, when the price of Wool is so low. The above Loom can be seen in operation at

NORRIS BLACK'S,
No. 18 KING STREET EAST, TORONTO,

The Agency for the SINGER SEWING MACHINES, which is another machine that every family should have. v5-13-1t.

Markets.

Toronto Markets.

"CANADA FARMER" Office, June 27th, 1868.

FLOUR AND GRAIN.

The market has been dull and in the higher grades of flour there has been nothing doing; prices are therefore entirely nominal, and cannot be quoted.

Wheat—The market has been without animation. There was some demand for spring, but at lower prices than holders were disposed to accept; $1.40 was the price buyers were offering; in general buyers would not give over $1.40. To-day the market improved, and holders, owing to an advance in the Eastern markets, are asking higher prices. Spring is held at $1.45 and $1.47, and Fall at $1 50. We, however, heard of no sales at those prices with the exception of a small lot of 200 bush spring, which sold at $1.45. The street prices have been as follows:—There is very little coming in on the street market; spring and midge-proof $1.38 to $1.40; fall $1.40.

Oats—The market has declined since our last review. Lots are now offering freely at 45c without buyers. Retail lots on the street market have sold at from 41c to 50c.

Barley.—There is nothing doing in this grain; car lots are nominally worth from $1 to $1 05. The few lots offering on the street market bring only from 60 to 70c.

Peas.—The market has been dull and drooping, lots sold as low as 74c. A better feeling has succeeded, however, within the past two days. We heard of no sales of car lots, but a small lot sold to-day as high as 79c.

Rye—Lower; worth only from 80c to 90c, with very little doing.

PROVISIONS.

Pork.—Mess pork is held at $22 50 to $23; with but little doing, and extra prime at from $15 50 to $16 50. *Cut Meat*.—Very little doing. We quote Cumberland cut at 10½c to 11c. *Eggs*—Scarce and higher; selling at from 11c to 12c. *Butter*—The market is firm with light supply—selling at from 12½c to 13c. *Cheese*—Unchanged, about 11 cents.

HAY—As high as $21 was paid for a few loads to-day; prices ranged from $12 to $21. *Straw*—Prices ranged from $12 to $15.

SALT—American, bbl. $1 60; Liverpool coarse in bags $1 20 to $1 30.

WOOL.—The market is quiet, but some buyers have advanced prices; the ruling rates now are 25c to 26c and 27c, the latter price being paid in silver.

HIDES AND SKINS.—Hides, green, rough per lb. 5½c to 6c., do. green, inspected 7c., do cured and inspected 7½c to 8½c. *Calfskins* green, 10c., do cured 12c., do dry 18c. to 20c.

Galt Markets, June 23.—Market still dull; the quantity of wool offered is much less than in former years. Farmers are holding back in order to manufacture for themselves. The price yesterday was 21½c silver, 20½c bills.

Guelph Markets, June 23.—Fall wheat, per bush, $1 40 to $1 45; spring wheat, $1 30 to $1 36; oats 50c to 51c; peas, 70c to 75c; barley, 90c to 95c; wool, 26c to 27c; *eggs*, per doz. 12c to 13c; butter, 12c to 13c per lb.

Hamilton Markets, June 22, 1868.—*Fall Wheat*, per bush. $1 40 to $1 45; *spring wheat*, per bush, $1 38 to $1 40; *barley*, do. $1 to $1 05; *oats*, do. 52c to 55c; *peas*, do. 80c to 85c; corn, do. 65c to 70c; *potatoes*, per bag, $1 25 to $1 50.

London Markets, June 23.—*Fall Wheat* per bush. $1 25 to $1 40; *spring wheat* $1 29 to $1 33; *barley*, 75c to 80c; *peas*, 60c to 70c; *oats*, 46c to 48c; *hay*, per ton, $9 to $10; *straw*, per load, $2 to $4; *pea straw*, per load, $2 to $3; *potatoes*, per bush. by load, 75c; *carrots*, do., do., 40c to 50c.

Montreal Markets, June 24.—*Flour*, superior extra, $7 50; extra, $7; fancy, $6 60 to $6 70; Welland Canal superfine, $6 50; superfine No. 1, Canada wheat, $6 30 to $6 70; superfine No. 2, Western wheat, $5; bag flour, $3 50. *Wheat*—Canada Fall, none here; Canada Spring, $1 50; Canada Western (Chicago No. 2), $1 50 to $1 62½. *Oats*—Per 32 lbs., 40c. *Barley*—Per 48 lbs., 90c. *Butter*—Dairy, 14½ to 18½c; store packed, 13c to 15c. *Cheese*—9c to 9½c. *Ashes*—Pots, $5 37½; pearls, $5 50. *Pork*—Mess, $22 75; Prime Mess, $16 00; Prime, $15. *Peas*—97½c. *Rye Flour*—$5 75

New York Produce Market.—*Flour*—Dull; receipts 3,800 bbls; sales 6,000 brls at $6 85 to $7 30 for super state and western; $7 65 to $8 00 for common to choice extra state; $7 70 to $9 75 for common to choice extra western. *Rye Flour*—Quiet at $5 85 to $10 40. *Wheat*—Limited export demand; receipts, 72,000 bush; sales, 630,000 bushels at $2 20 for choice No. 1, Spring; $2 12 for No. 2 do. *Rye*—Quiet. *Corn*—Dull; receipts 118,000 bushels; sales, 40,000 bush at $1 05 to $1 06½ for new mixed Western afloat, and $1 11 for white western. *Barley*—Dull. *Oats*—Active and in good speculative demand; receipts, 34,000 bush; sales, 36,000 bushels at 83c for western in store; 83c to 83½c for western afloat.

Chicago Markets, June 24, noon.—William Young & Co.'s report.—*Wheat*—Receipts, 24,000 bushels; shipments, 45,000 bushels. No. 2 wheat, quiet at $1 99. *Corn*—Lower at 88½c; receipts, 145,000 bushels; shipments, 60,000. *Pork*—Unchanged

Milwaukee Markets.—June 24, noon.—Wm. Young & Co.'s report.—Wheat—Receipts, 23,000 bushels; shipments 17,000 bus. No. 1 wheat, irregular but moderately active at $1 07½ to $1 08; No. 2 wheat irregular but moderately active at $1 83½ to $1 89. Flour dull. Pork unchanged.

THE CANADA FARMER is printed and published on the 1st and 15th of every month, by the GLOBE PRINTING COMPANY, at their Printing House, 26 and 28 King Street East, Toronto, Ontario, where all communications for the paper must be addressed.

☞ Subscription Price $1 per annum, (POSTAGE FREE,) payable in advance. Bound volumes for 1864, 1865, 1866 and 1867, may be had for $1 50 each. Subscribers may either begin with No. 1 of the present Volume, or with the first No. of any preceding volume. No subscriptions received for less than a year, and all commence with the first number for the respective years.

CLUBS will be furnished at the following rates:—

TEN COPIES for ..... NINE DOLLARS.
TWENTY COPIES for ..... SIXTEEN DOLLARS.
FORTY COPIES for ..... THIRTY DOLLARS.
ONE HUNDRED COPIES for ..... SEVENTY DOLLARS.

To Agricultural Societies ordering more than 125 copies, THE FARMER will be sent at SIXTY CENTS.

THE CANADA FARMER presents a first-class medium for agricultural advertisements. Terms of advertising, 20 cents per line space. Twelve lines' space equals one inch. No advertisement taken for less than ten lines' space.

Communications on Agricultural subjects are invited, addressed to "*The Editor of the Canada Farmer*," and all orders for the paper are to be sent to GEORGE BROWN,
Managing Director.

VOL. V. No. 14. TORONTO, CANADA, JULY 15, 1868. POSTAGE FREE.

The Field.

Blank Places in the Turnip Field.

OWING to defect in the seed, or to fly ravages, there will often be blank places in the turnip field. These to a farmer of neat instincts and habits are a great eyesore. Moreover, they involve waste of rich land, valuable manure, and costly labour. When these blank places amount to a considerable proportion of the field, the loss of crop thereby occasioned becomes a serious item. It is therefore every way desirable that these blank places should be filled up and turned to some useful account. This may be done in a variety of ways. The best, were it practicable, would be to transplant from rows that have an excess of plants, and so occupy the vacancies and make the field complete. But this can hardly be said to be practicable, though we believe it is done to some extent by British farmers. The turnip does not transplant kindly, and only submits to the process in a humid climate, or during a remarkably wet time. Even under such conditions, the plant is checked and the bulb stunted. Mangolds are much more docile under transplantation. Indeed, during a spell of moist weather, they can be transplanted almost without their knowing it. Hence there need be no blank spaces in a mangold patch—ought to be none.

Blanks in the turnip field may be filled up by sowing Yellow Aberdeens, White Globes, Stubble or White Stone turnips. These mature in a much briefer time than the Swede, and though not so valuable, are by no means to be despised. They may be fed in the late fall or early winter, and made to help materially in eking out the supply of roots. The Yellow Aberdeen is the best of these late varieties, and will come to a very respectable size if the season be good, though sown three or four weeks after the general crop of Swedes. A good supply of White Stones is by no means bad filling for a bin in the cellar, or for the pot on days when there is a "boiled dinner" preparing in the kitchen. It is very little trouble, when the turnip crop is gathered, to separate the different kinds, and convey them to their proper destination.

There is another mode of filling these vacancies, which may be mentioned, though the suggestion is rather late to be of practical value the present season. It can, however, be made a note of, and acted on another year. We refer to filling up with another kind of forage crop, namely, the cabbage. There is no better expedient than this, and none that can be more easily carried out. Moreover, cabbages are greatly relished by cattle in the winter time, and are especially valuable for milch cows. Being of easy culture, the wonder is that they are not more extensively grown as a field crop. The plants require to be grown until fit for transplantation in a seed bed, which should be located in some sheltered and sunny spot, and the seed sown in early spring. The soil of the seed-bed should be very rich, well-worked and mellow. In sowing a quantity for field culture, of course a good-sized bed will be required, and it is the better plan to sow in drills, as the plants can then be more readily hoed and weeded. They will also require thinning, and if the plants can be used at different intervals, it will be well to take the larger and stronger ones first, leaving the feebler ones to grow into more vigorous condition. A moist time should be chosen for transplanting, and the work done with a tool known among gardeners as a "dibble." This tool is usually made of an old broken spade handle. The top part of the handle, about eighteen inches in length, is what is used for the purpose. A gradually tapering point is made to it, which is pushed into the soil, and withdrawn with a turn of the hand. Into this dibble-hole the young plant is set, and the dirt firmly pressed around it. The most expeditious way of doing the work is for one person to make the hole and drop the plant beside it, while another sets the plant. This is an operation in which the "young folks at home" can be employed to advantage, as their backs are short and their fingers nimble.

The Drainage of Land.

To the Editor of THE CANADA FARMER:

SIR,—The principal object of draining is to take away surplus water; but in effecting this other important benefits are secured. It is obvious that a larger quantity of water in the soil than is required for the support of the plants is injurious. It is injurious in various ways. That wet lands are cold and sour is a common expression, and an acquaintance with the principles which this condition of the soil involves shows that the popular idea is correct. It has been repeatedly proved that evaporation produces coldness; that in the exhalation of moisture heat is carried off, and this is one of the reasons why a wet soil is really a cold one. That such a soil is also sour is proved by the fact that vegetable matters form acids when decomposed in water. The sourness of peat may be taken as an example. Prof. Johnston observes, "When soils are soaked in water their vegetable matter either decomposes very slowly, or produces acid compounds more or less injurious to the plant, and even exerts injurious chemical reaction upon the earthy and saline constituents of the soil." One of the first objects in the production of any plant is to secure a temperature congenial to its habits. Every person may have observed that vegetation makes no progress till the weather becomes sufficiently warm. Different species of plants require different degrees of heat, but as a general rule those which grow in the lowest temperature are the least valuable.

The effect of drainage has been found highly favorable in raising the temperature of soils. Experiments have been made which proved that at seven inches below the surface the average degree of heat for thirty-six successive days, on a soil which had been underdrained and pulverized, was ten degrees higher than on a soil precisely similar that had not been drained and worked. The more rapid growth and perfect maturity of crops on drained land is doubtless attributable to the higher temperature thus obtained, and is an evidence of the great value of drainage in high latitudes where, from the shortness of the season, the results of the agricultural labours are peculiarly uncertain. It may be safely assumed that draining is the basis of the great improvement which has taken place in British husbandry within the last fifty years. In Canada the practice of draining systematically can hardly be said to be introduced. Various trials have, however, been made in different parts of the country; the subject is attracting great attention, and we may expect shortly to see the business carried on largely and profitably, provided we can obtain an Act to compel neighbours to make an outlet for farms lying above them similar to the one for surface water. It has been objected that drainage is less necessary here than in Britain, that in our drier climate crops are more liable to drought than moisture. To this it may be replied that proper drainage, with a thorough working of the soil, is the best possible protection against drought. A little observation will convince any person that those lands are most affected by drought which at some seasons of the year are too wet. Clays which are not drained keep the water so long on the surface that the soil runs together and forms a mortar, which, when the water is evaporated, becomes like sun-burnt bricks, unworkable and totally unfit for the growth of plants. On the hard pan soil the surface is completely saturated with water in spring, or in wet weather, the compact subsoil not permitting it to soak into the earth. In both cases the workable soil is usually thin, and as soon as drought comes on, the plants droop, and, "because they have not much root, they wither away." Crops on such soils are very precarious; the only bed for their roots at any time is the little portion moved by the plough, and it is but for a small part of time, comparatively, that even this is wholly available to them—it being almost always either too wet or too dry. The roots cannot perhaps penetrate the hard subsoil, or if they do are liable to be brought in contact with substances more or less poisonous to vegetation. The effect of drainage in such cases is to increase the depth of the soil, to render it more permeable to the roots and less liable to be affected by drought.

The first action of the drain is to take the water from that part of the soil with which it is in direct

contact. A contraction of the soil soon follows and cracks are formed, beginning at the drain and extending laterally and vertically, which admit the percolation of water and conduct it to the drain. When the soil is thus brought into a state which allows the water readily to pass through it, the former difficulties of its running together and baking are obviated, the soil remains open and friable, and plants are protected against extremes of wet and drought. It is a fact that plants suffer less from drought on a friable soil than on a compact one, as may be seen by a comparison of crops on clay and loam. This results from two causes: the roots of plants have more scope in a loose soil and are thus enabled to draw support from a greater source. A mellow soil is also most moist in time of drought, pulverization favouring the ascent of moisture from below as well as its absorption from the atmosphere. A heap of moulding sand will seldom dry except to a little depth, while hard clay in the same situation will become almost destitute of moisture. And it is now a proposition regarded among the best English and Scotch farmers as completely established, that drained land is not only better in wet seasons, but in dry seasons also.

E. B.

Broadcast and Drill-Sowing.

THE following is part of a discussion on the comparative merits of broadcast and drill-sowing of grain, which took place at a recent quarterly meeting of the Morayshire Farmers' Club, as reported in *The Farmer*, (Scottish) of May 20th, 1868.

"The Chairman said it was proposed that they should have some little discussion on the merits or demerits of drill-sowing compared with broadcast sowing; and he might initiate the discussion by stating his own experience and opinion. He had had a drill-sower in use for several years, and he thought it particularly well adapted for the generality of soils in Morayshire, and especially so for the farm of Spynie. In light soils the drill-sower deposited the seed equally and at a uniform depth. The braird comes up very regularly, and so equally distributed that for himself he was satisfied it was of great advantage to use the drill machine, provided they got a good implement. The one he used was made by Mr. Ben. Reid, Aberdeen. They made some little blunders at first, and even the second year, by making little bits of slips when turning the machine; but since then they had had the work most excellently done. There was a great saving of seed—about a bushel per acre. He thought they might calculate upon the same return after saving a bushel of seed upon what they would use with broadcast sowing.

"Mr. Walker, of Altyre, said he had no experience in drill-sowing, but he should like to hear the difference in seed and crop from the two systems. There was said to be a very considerable saving of seed, but he should like to hear the time and labour occupied by the drill-sower, so that they could know what actually was the profit of working it, and whether, by sowing thinner the crop is much heavier or lighter than it would be otherwise. Those who have experience might give them information on this point.

"Mr. Harris, Earnhill, said that for the last four years he had sown his wheat with a drill machine eight feet broad, and with the rods four inches asunder. He had gradually decreased the quantity of seed, and he must say his crop had as gradually increased in weight and quality. He had never used the drill for spring corn, for which he did not think it was of so much advantage, because it certainly took a long time to sow the drill, and whatever way they put down spring corn, it would grow. The seed took only a short time to germinate, and the land was so late in being prepared after turnips that there was really no time to lose. As to the time taken in sowing, that depended upon the machine. If the frame measured from seven to ten feet they could sow from ten to twelve acres a-day with a pair of horses, though that was certainly heavy work for the animals. He thought, however, that the time lost with the drill was thoroughly compensated for by the saving of seed effected. Before he got the drill-machine he used to give from three and a-half to four bushels of seed per acre. This year he sowed wheat with two bushels per acre. He thought he had made a great mistake when he saw the braird rising, and too much black land appearing to the sight; but that morning he walked through the field, and however the crop might turn out, he did not think it would fail for want of plants. There was one thing to take into consideration in sowing ten or twelve acres a-day with the drill machine—namely, that they were conducting three operations at once. They were depositing the seed, they were packing the land, and at the same time saving a harrowing; so that he did not know that the labour would be found to be greater than by sowing with a broadcast machine or in any other manner, while certainly the saving of seed was considerable.

"Mr. Patterson, Mulben, said his practice for the last eight or nine years had been to sow with a broadcast machine, but last year on the farm of Lennox, in Dallas, he introduced a one-horse drill-sower, made by Mr. Benjamin Reid, Aberdeen. There were about three or four acres of very steep land, which the men sowed with the hand, and in which they put down six bushels to the acre. The rest of the field, about the same in breadth, was sown by the drill, and only got three bushels to the acre. Three very practical men asked his leave to go into the field and examine the two crops, and they reported to him that the part sown by the drill with three bushels of seed was a better crop, more equally grown, and thicker than the other. He had gone on with the drill this year, and so far as he could see it was an advantage. He had not, however, as yet adopted the drill machine at Mulben.

"Mr. Walker—You say the land sown by the hand was steep, but was the quality of the land equal in both cases?

"Mr. Paterson—The part sown by the hand was a much better sort than the other part. He did not thrash out the crops separately and measure them; he only took an estimate of them by the eye. The gentlemen who took the trouble to go over the field, however, were also perfectly satisfied that the difference in the crop was in favour of the part sown by the machine.

"Mr. Garden, Grangegreen, said he had sown his corn with the drill machine this year only, and he was very much pleased with the braird that was coming up. The machine saved about a bushel an acre of seed, but unless the crop turned out satisfactory he would not give much consideration to that. The drill certainly involved very much more labour, but still, with a little activity, they could get over that. He sowed about sixteen acres a day with different relays of horses. He put a man to manage the steering machine, and also a man to walk behind to see that the machine wrought properly. This supervision was very necessary to see that the work was well done, because he would not on any account have his fields sown in the way he saw some done by the drill machine.

"Mr. Yool, Coulart Bank, said he had used a drill machine for eight years, having got it from East Lothian. It had eight inches between the coulters. He had made no rigid experiments to ascertain whether the broadcast or drill-sowing was most profitable, or made the greatest returns; but, judging from the appearance on fair good land in good condition, he had no hesitation in saying that the eight-inch drill had been satisfactory and amply remunerative. On very light land he thought eight inches was too great a distance for the drills to be apart. They could not make the seed cover the land where the soil was light, but where there was good land they could cover it. There was certainly a saving of one bushel per acre on the seed. He did not think that the labour was very much more; and he quite agreed with Mr. Harris that the drill-sower accomplishes one or two other operations. It consolidated the land and saved harrowing. If they could get the drill machine, with a frame attached to the back containing a grass-sower, as he believed they had in Aberdeen, it would be a great saving. The grass being deposited at the same time as the grain, would save an after broadcast sowing with a machine or by hand. He intended to get next year a machine with a narrow drill for his light land. He had a very good example of the advantage of sowing with the drill on a field verging on a piece of blowing sand. He drilled the good land, and sowed the light land broadcast. Two or three days afterwards, a very strong breeze set in, and very soon the broadcast sown seed was left bare; while on the drill-sown part immediately verging upon it there was not so much as a single seed visible on the surface, and on scraping away the earth to the depth of about half an inch the braird was found coming on finely. If the part where the seed was blown had been drilled with a narrow drill, it would have been all saved. He had no doubt that much of the seed thus exposed would never germinate, for it was just beginning to spring when several dry days came, which, together with the exposure, would prevent it germinating. He found with drill-sowing that though the corn did lodge, it did not go down so flat as it would do if sown broadcast. The root had a firmer hold on the ground, and though the crop was blown over, it did not lie so closely at the root as to let it lodge compactly on the ground, and prevent it from ripening. That was a very considerable advantage on a farm with a quantity of good land. He thought it would be very desirable that some members should make rigid experiments on as good land as could be got. Impressions from merely looking at the crops were all very well, but until they got the thing measured and weighed they could not be sure. He might say that he sowed spring corn as well as wheat in the autumn with the drill, and he thought it was a great advantage in both cases."

Cultivation of the Beet for Sugar.

A French literary *savan*, M. Merais, lately presented to the Academy of Sciences of Paris, a paper on the cultivation of the beet for sugar, which propounds a theory worthy to be labelled "important if true." Moreover there is great probability that it is true, for it seems reasonable. The leading features of this scientific theory are given as follows in *The Grocer*:

"The results at which M. Merais arrives are, that if in the choice of seed plants care be taken to reproduce those roots which are richest in sugar, the result will be the production of a radical type somewhat concave in form, with large hollow neck, carrying several heads; such in fact are the characteristics which distinguish the variety obtained under such conditions by M. Louis Vilmorin. But if such roots possess the grand advantage of richness in sugar, they have the grave inconvenience of yielding but a poor weight per acre, and also of striking many lateral roots, which are equally inconvenient for cultivation and sugar-making. If, on the other hand, those beets are chosen for seed which are roundest, heaviest, and have the fewest roots, which is the common practice of farmers in order to obtain as heavy a crop as possible, the result will be the finest roots to look at and the poorest in sugar.

"The grand object, says M. Merais, in order to improve the beet with a view both to the culture and the manufacture, is to obtain at the lowest cost possible the maximum of extractible sugar per acre, and for this purpose it is necessary to study carefully all the conditions of the case:—1. The richness of the roots in sugar. 2. The weight of the crop per acre. 3. The purity of the juice, and especially the quantity of foreign salts which the roots contain. 4. The proportions of pulp to juice, taking into account the modes of extraction. 5. The convenience of cultivation and manufacture. It is very probable that in pursuing this course we may arrive at a type of beet intermediate between that which has great tap roots and that which has scarcely more than a few threads, and also perhaps at an average form of root, such as the conical or slightly bulging form."

Salt as a Manure.

A CORRESPONDENT sends in the following clipping from a local paper, with a request that we would give it a wider circulation by inserting it in the CANADA FARMER. The communication is addressed to the *Goderich Signal*, and is as follows:—

Thinking the following extracts from Mr. Johnston's book of lectures on Agricultural Chemistry would be beneficial to the Farmers of Huron, by showing them experiments which have been actually tried in the old country—I send you them. Mr. Johnston says:—The use of salt as a manure has been long recommended; it is still extensively and *profitably* applied to the land. Some of the most carefully observed results which have hitherto been published are contained in the following table:—

Locality & Grower.	*Produce per acre.*				*Quantity per acre and kind of soil.*
	Unsalted.		*Salted.*		*Bushels.*
Essex; G. Sinclair, Upon Wheat.....	16½	bushels	22¾	bus	11 after Barley.
	11½	"	21	"	5½ " Beans.
	16	"	17¾	"	Sown with seed after Peas.
	12	"	28½	"	5½ applied after sowing—after turnips.
Suffolk; Wm. Ranson on Barley	30	"	51	"	16.
Near Richmond, at Aska Hall on hay.	tons.	cwt.	tons	cwt	
	2	10	3	12	5, on thin light soil, with clay sub-soil.
	2	10	2	12	5, light soil on gr'l.

Now, there are certain localities in which we can say beforehand that salt is likely to be abundant in the soil. Such are the lands that lie along the sea coast, or which are exposed to the action of prevailing sea winds. Over such districts the spray of the sea is constantly borne by the winds, and strewed upon the land, or is lifted high in the air, from which it descends afterwards in the rain. (Dr. Madden has calculated that the quantity of rain which falls at Penicuick in a year brings down upon each acre more than six hundred pounds of salt.) This consideration, therefore, affords us the important practical rule with regard to the application of salt as a manure, viz:—*that it is most likely to be beneficial in spots which are remote from the sea, or are sheltered from the prevailing sea winds.*

THOS. WEATHERALD.

Goderich, June 4, 1868.

Root Crops and their Management.

MR. ATTCHISON, Abinger Hall Farm, Surrey, writes in *Bell's Messenger*, as follows, on this subject:—"The first and most important point is the preparation of the soil. In all cases that should be done, if possible, in the autumn. Have the land well cleaned, the farm-yard manure carted out, and ploughed and subsoiled, or cultivated deep by steam, before the frost sets in; and only use the cultivator and harrows in the spring. Then, with two or three hundred weight of guano per acre, you stand the prospect of a good crop of roots. The safest and best for the south is mangold-wurtzel and kohl-rabi. I have fourteen acres of them mixed, two rows each; and six acres of carrots, mangolds, and kohl-rabi all mixed, and have had 125 sheep feeding on them since the beginning of October. They will last them three months, and I have never seen sheep do better. They are all cut up by the turnip cutter and mixed; for fattening stock do better with a mixture, and you can grow more produce of a better quality. It may not look so well to the eye, but it is much better for the pocket and the farmer's profits and the health of his stock. I have stored all our other mangolds, and the kohl-rabi I intend to feed off by sheep. There are no roots that you can grow that sheep do so well on as kohl-rabi. They should all be sown by the end of April, and you can get any quantity per acre, by using plenty of manure; as they are like mangolds, you cannot give them too much. I used only two and a half hundred weight of Phospho-guano, and four hundred weight of salt per acre, and well horse-hoed and stirred the soil to let in the air; and hand-hoed them to keep them clean. The land, when fed off with half the crop, will be in a very high state of condition, and fit to grow anything you wish to put on it."

Weeding Potatoes with Sheep.

IT may not be known to farmers in general that it is a common practice in some of the potato-growing districts to turn flocks of sheep into the potato fields for the purpose of eating down the weeds. The sheep will not touch a potato vine; they can not be starved into eating them. This Pasturing with sheep is very advantageous when the crop is a late planted one, so that the hoeing cannot be completed until the hoeing or harvest is finished. At the growing season it is the planter's aim to keep down the grass and weeds so that they may be covered with dirt by the cultivator and hoe, when these are used. Pasturing with sheep will attain this object. Early planted crops, the cultivation of which is completed in the first half of the summer, frequently become grassy and weedy before the time of digging—when the size of the tops precludes cultivation. In this stage the sheep are economical weeders. It is hardly necessary to mention that the food thus given to the sheep makes a double profit, inasmuch as it costs absolutely nothing, while labor is saved and weeds prevented from seeding in the crop.—*Rural.*

Burdock.

No good farmer will allow this coarse and disagreeable weed to flourish on his farm. After a few plants have been allowed to go to seed, a long time will elapse before they can be exterminated. As burdock is a biennial plat, the seeds germinate one season and produce seed the next. After this, the root and all dies. Burdock is seldom seen in cultivated fields. In neglected nooks, where the ground is rich and bare, burdock will supplant everything else.

The best way to eradicate the plant is to cut it away with sharp hoes, two or more inches below the surface of the ground, late in autumn, when the water will enter the roots and destroy them. If the ground where they grow can be ploughed, they may be easily exterminated, unless there is much seed in the soil, which a few years of cultivation will destroy by vegetation.

At this season of the year, burdock plants may be seen in many nooks, spreading their broad leaves over an area of ground, allowing no other plant to live beneath them. If they be cut off, there will be sufficient vital energy in the roots to send up a new system of stems, which will produce a bountiful crop of seed before winter. But cut them off a little below the surface of the ground with a sharp broad hoe, or grubbing hoe, or mattock, and put a table spoonful of salt on the top of the tap root, and burdock will never sprout from such roots.—*Ex.*

A Somersetshire Stile.

A CORRESPONDENT in the *Cottage Gardener* sends the following illustrated descriptions of a kind of stile which appears easy of construction, and effectual against larger animals, though it would be of little use against sheep and pigs:—

"As the merits of the Cornish stile have been discussed in the last few numbers of your journal, I venture to call attention to an invention of my own, which I have had in use for nearly two years, and which has been found to answer every purpose for which a stile is required, even to a free passage of your correspondent's 'departed crinoline.'

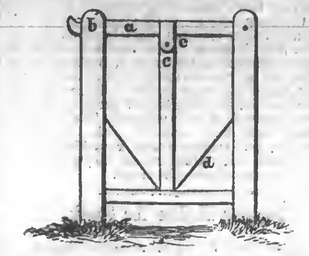

FIG. 1.

"You will observe from the above engraving (*fig.* 1) that it is very simple in construction, and entirely self-acting. It has no fastening, as the cross-bar (*a*), after being lifted up for the person to pass through, falls back to its place in a slit in the post (*b*) by its own weight, so that it cannot be left open, a great desideratum in stiles and gates of all kinds.

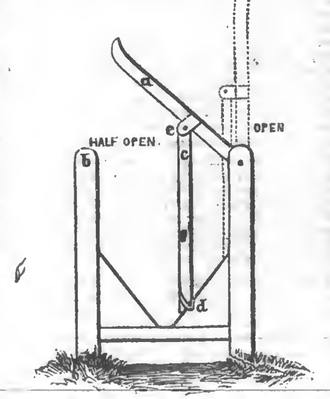

FIG. 2.

"When the bar (*a*) is lifted up (see *fig.* 2), the pendant (*c*) turning on the pivot (*e*) naturally rises with it, and runs up to the bar (*d*), to which it is fastened by a ring at the bottom, thus leaving a perfectly clear space between the posts for a person to pass through. The stiles are made of iron and wood as required, and are found to answer well in other places besides this, as the orders now rapidly coming in abundantly testify. It is patented."

Plaster for the Hop Aphis.

MR. F. COLLINS, of Rochester, N.Y., a gentleman thoroughly conversant with hop culture, and patentee of the best system of training the plants we know of, strongly urges all engaged in the business of hop-raising to be ready with plaster to avert the ravages of the aphis by a thorough dusting of the vines at the first appearance of this insect pest. He says that simple as this remedy is, it is entirely effectual. Indeed the remedy is even more simple than appears at first sight, inasmuch as common road dust will answer the same purpose as the plaster so far as the insects are concerned, but plaster is to be preferred because it not only destroys the aphis, but benefits the plant. He mentions in confirmation of his statements, that a number of hop-yards lying under the lee of a railroad, and swept during the summer by its clouds of fine dust, were entirely free from aphis, and produced fine crops, while yards at some distance from the track were badly infested, and the product destroyed.

On Drying Corn in Sheaves.

THE following extract is well worth the attention of both landlord and farmer:—"Mr. Stephens, of Edinburgh, communicates to the *Journal of Agriculture*—'The simplest method of securing the crop after cutting it down from being damaged by standing long in stooks on the ground, is that universally practised by the agriculturist in the woody parts of Sweden and Norway, and which never fails in completely protecting at least nine-tenths of the grain from growing in the sheaf, as well as the straw from any serious injury. In those districts every farmer provides as many *sades stor*, corn stakes (that is stakes for drying the grain on), as will be necessary for the quantity of his growing crop. They are generally made of young white pine, eight feet long, about one and a-half inch diameter at the top and four inches at the bottom. The upper end is pointed, to allow the sheaf to pass easily down over it, and the lower end is likewise pointed to facilitate its being fixed in the ground. When a field of grain is ready for the sickle, the stakes are conveyed to the spot, and the reapers proceed with the work; the stakes are put up in rows behind them, in the same manner and at the same distance from each other as is common in stooking the crop. A man, with the assistance of an iron crane or spit, will set up five hundred of these in a day. The next operation is to put the sheaves on the stack. This is performed by raising the first sheaf up to the top of the stake and passing it, with the root end downwards, to the ground, the stake being kept as nearly as possible in the middle of the sheaf. The sheaf then stands perpendicular and round the stakes. The second sheaf is fixed on the stake in an inclined position, with the grain end sloping a little downwards, the stake passing through the sheaf at the band in a transverse manner, and in that position it is pressed down to the first sheaf, and thus forms a covering to it. All the other sheaves are threaded on to the stake in a similar way as the first sheaf put on, keeping them all one above another, with the root-ends facing the south-west to receive as much of the sunshine as possible, on account of the greater quantity of grassy substance they contain at the end. As each sheaf thus acts as a covering to the one beneath it, and as there is only one that can touch the ground, rain cannot at any time penetrate through them, and it is very rare that any single heads of grain on a stake are injured. I have witnessed these operations performed with as much expedition as actually attends the common way of setting the crop in the field in stooks. The number of sheaves put upon each stake is generally fifteen or sixteen. The advantages arising from the above simple manner of protecting the crop are many, exclusive of the consideration of the grain and straw being preserved in a wholesome state. The farmer by it is enabled to commence reaping early in the morning while the dew is yet on the grain. Partial rainy weather does not prevent his operations; he can employ all his people in cutting down the crop before carrying home part of it, and when he does commence carrying it home not the least particle is shaken out, for, instead of throwing a single sheaf into the corn cart or waggon at a time (by which much grain is frequently lost), the stake with the whole of its contents is taken up, put into the cart, and carried to the corn-yard. When the crop is all carried home the stakes are collected and laid aside to be similarly applied the succeeding year, and when carefully kept during the period they are in use they will last twenty or thirty years. I have known many farmers residing on the plains of Sweden, where wood is extremely scarce, who, rather than be without such preservatives of their crop, choose to purchase them at a dear rate and transport them thirty or forty miles to their possessions. Indeed, the practice of staking the grain is there so general and so beneficial that the number of stakes used is often taken notice of when a lot of land is offered for sale.'" The above method of securing the crop during a wet season is so well adapted for our variable climate, and being cheap, simple, and efficient, it must be the stupid adherence to old habits that hinders our farmers from adopting such a mode. I believe in some parts of Aberdeenshire it is adopted during wet seasons with success, though many projects made of late induce me to think that a lesson might be taken from Norwegian and Swedish farming.—J. KERR, Galashiels, in *Inverness Courier.*

Stock Department.

A Sensible Proposition.

"G. G." (George Geddes), one of the *Country Gentleman's* most prolific correspondents, an old country man by the way, proposes as one measure which would tend greatly to the improvement of farm stock, that a tax be levied on all stallions, bulls, rams, and boars." He says:

"If every horse colt not altered when a year old entailed a tax of $20 per year upon his owner—if every bull calf of six months old had to pay $5, and the same per annum afterwards, and every ram lamb and boar pig were taxable at $2 per year, commencing at three months of age—it would "do away" with most of the worthless brutes, and in five years' time the live stock would be worth very many millions more, and in the course of a few generations there would be nothing living but had some good blood in it, for the dullest of farmers would not pay taxes on the hideous objects which now rove around."

We entirely concur with "G. G." and cheerfully help to pass his proposition round, in the hope that our legislators may profit by it, and aid in abating the masculine nuisance in question. The great proportion of the wretched creatures referred to are of no earthly use to their owners, and their existence tends more than any other one circumstance to perpetuate worthless kinds of stock. In consequence of accidents which will happen in the best regulated families, great damage is done to better bred animals by unlucky crosses, which to all careful, intelligent farmers, are indeed "crosses" in more senses than one.

Nutritive Value of Food for Cattle.

The following table will afford some valuable suggestive information. It shows the nutritive value of several kinds of food—first according to theory or from analysis, and secondly according to the average of several different experiments. The figures given represent the quantity in pounds to be taken of each kind in order to reach a standard of nutrition—as, for instance, that of hay:—

	Value by Analysis.	*Value by Experiment.*
Good Hay	100	100
Wheat	47	43
Peas	20	44
Beans	29	46
Rye	58	49
Barley	65	51
Indian Corn	70	56
Oats	60	59
Buckwheat	74	64
Linseed Oil-Cake	22	66
Red Clover Hay (well cured)	77	95
Potatoes	324	195
Oat Straw	364	220
Ruta-Bagas	676	262
Carrots	412	280
Field Beets	291	346
Rye Straw	502	355

One of the most valuable substances for the food of cows in winter is *bean meal*. Fed upon it, with hay, although giving less milk than when fed upon grass, they have actually yielded more butter. Bean meal is particularly valuable for the production of cheese. In using it the meal should be diluted with bran, cut food, or Indian meal.

The foregoing calculations have been still more simplified by the following condensed statement of the "constituents of feeding materials." Perhaps from it a better idea may be obtained of the proportionate value of various kinds of food:—

PARTS IN 100.

	Real Food.	*Water.*	*Ash.*
Beans	82½	14	3½
Peas	60	16	3½
Oil Cake	75½	17	7½
Swedes	14	85	1
Turnips	10	89	1
Mangolds	10	89	1
Carrots	12	87	1
Common Hay	76½	16	7½

One pound of flesh, it is said, will be produced, under favourable circumstances, by the consumption of

Turnips	160 lbs.	Milk	25 lbs.
Potatoes	50 "	Oat Meal	9 "
Peas	3½ "	Flour	7½ "
Beans	4 "	Barley Meal	7 "

The Descendants of Captain Cook's Pig.

The native (Maori) saying is, "As the white man's rat has driven away the native rat, as the European fly drives away our own fly, and the clover kills our fern, so will the Maoris disappear before the white man himself." It is wonderful to behold the botanical and zoological changes which have taken place since Capt. Cook set his foot in New Zealand. Some pigs which he left with the natives have increased and ran wild in such a way that it is impossible to destroy them. There are large tracts of the country where they reign supreme. The soil looks as if it were ploughed by their burrowing. Some stationholders of 100,000 acres have had to make contracts for killing them at 6d. per tail, and as many as 22,000, on a single run, have been killed by adventurous parties, without any diminution being discernible. Not only are they obnoxious by occupying the ground which the sheep-farmer needs for his flocks, but they assiduously follow the ewes when lambing, and devour the poor lambs as soon as they make their appearance. They do not exist on the western side of the Alps, and only on the lower grounds on the eastern side, where the snow seldom falls; so that the explorer has not the advantage of profiting by their existence where food is the scarcest. The boars are sometimes very large, covered with long black bristles, and have enormous tusks, resembling closely the wild boars of the Ardennes, and they are equally savage and courageous.—*Dr. Haast.*

Summer Shelter for Stock.

Mid-summer, and during the months of August and September, we shall probably have much hot and sultry weather. Give therefore a little attention to your stock, in the way of preparing a temporary shed in the pasture, as a shelter from the scorching heat of September sun. Trees, which are more or less common in all pastures, afford a good shade, but a cheap temporary shed is even better, and especially if there is no other protection. An open shed, through which the air will freely pass, and near a brook if possible, should be erected and provided with boxes for holding salt, that the cattle may partake of it at pleasure. In the middle of these hot summer days they will not eat, and how much better and more humane for the farmer to build such a shed in which they can lie and rest themselves. Sheep especially, as well as milch cows, need such a protection. Cattle should also be stabled, these nights in August and September, in a cool and well ventilated place. A shed built in a pasture would cost but a trifle, and could be taken down after the weather became cool.—*Cor. Dixie Farmer.*

Live and Dead Weight in Sheep.—The English rule is to weigh sheep when fatted, and divide the weight by seven and call it quarters. Thus, sheep weighing one hundred and forty pounds, would give twenty pounds a quarter as the dead weight. If the sheep are in good condition, this rule is sufficient for all purposes. Poor sheep will fall below the mark, and extra fat ones go over it.

Free Martins.—It has been the general opinion, and I certainly must say that I was of very strong opinion myself, that Free Martins do not breed, but I am now entirely convinced to the contrary, from the following fact:—Young Duchess, a full blood Durham, was a twin with a bull calved August 20th, 1865, got by Butterfly 2d [91,] Canada Herd-Book, served August, 1867, and on 5th of June, 1868, she bred a heifer calf, which she is now suckling. Duchess, the dam of young Duchess, was bred by the late Hon. Adam Fergusson, Woodhill, Ont., was calved July 1st, 1850, making her 15 years old when she bred these twins. She has been a pretty regular breeder, breeding twins in 1859 to Ethelbert, [234], Canada Herd-Book. Jos. Kirby. *Milton, Canada.*

Veterinary Department.

Swelled Legs.

Regulation of the diet is an essential part of the treatment of swelled legs, and especially of that form of the disease which was last described, as affecting "grass" horses—animals whose systems have become deranged in consequence of injudicious feeding with indigestible material, or with ordinary aliment in quantities disproportioned to the animal's requirements. To correctly adjust the supply of nutriment to the amount of waste of tissue is not easy, but it is nevertheless of great importance in the treatment of the morbid condition of which swelled legs is one of the consequences. No difficulty would be encountered if it were only necessary, in dealing with a plethoric animal, to reduce the condition; active depletive measures would effect this object in a short time; but, while under such treatment the swelling of the extremities would quickly but temporarily subside, the debility which would result would certainly tend to increase the disease. So far from there being a necessity for depletive treatment, the animal must be looked upon as already in a condition of weakness. Despite the increase of bulk, there is a want of energy and activity in the functions, due to the enervating influence of rest and repletion. Excessive deposition of fat is scarcely compatible with a state of health under any circumstances; and when it is traceable to improper diet and inaction, it is always associated with debility and disordered nutrition. Therefore it is necessary to adopt a system of dietetics and exercise calculated to diminish the animal's bulk, by causing the removal of superfluous fat, to improve the tone of the muscular system by exercise, and to supply the necessary quantity of nutriment in the most easily digestible form. The value of any kind of food cannot be determined by merely calculating the exact amount of azotised matters which it contains. It is possible that the nutritious principles may be so combined with other constituents as not to be capable of being assimilated. For this reason we object to the use of beans for animals in a debilitated condition, whether plethoric or emaciated; large quantities of straw are similarly detrimental; and for "grass" animals food which is rich in fat-forming constituents must be avoided. Oats, with a small proportion of bran and old hay, with green food or roots to be added as alteratives, will constitute a liberal and safe *régime*. Exercise must be gradually increased as the condition improves, and there is no better test of improvement than the restoration of firmness to the flaccid muscles. Meanwhile the occasional use of a mild dose of laxative medicine will be beneficial, and once or twice a week two drachms of powdered nitre may be given in a mash. If the swollen legs are complicated with cracked heels or grease, the treatment which has been suggested for these diseases in previous articles may be used; but if no discharge or wound exists, the local treatment should consist of frictions and bandaging when no heat or pain are present, and of warm fomentation, followed by sedative lotions, if the swelling is tense and the limb tender to the touch. Perseverance and patience will, in perhaps the majority of cases, be rewarded; but it must be admitted that obstinate cases of chronic swelled legs are not uncommon. No treatment seems to make any impression in such instances, and the skin of the swollen extremity ultimately becomes thickened permanently by a deposit of fibrinous material, that may be said to form a part of the organism. Animals affected in this way, however, generally belong to the poorer equine classes; and, if the progress of the disease could be traced, it would in most instances be found that the malady had been neglected in its early stage. Instances, nevertheless, are now and then met with in well-kept and tolerably well-bred horses, which are said to be "humourry," just as among human beings we find persons afflicted with a tendency to scrofula, or consumption, or gout. And in dealing with such subjects the most that can be expected is that, by careful treatment and avoidance of all causes which are likely to develope the predisposition, the tendency may be so checked as not to seriously inconvenience the individual or the animal. It will be apparent, from a review of what has been stated upon the subject of swelled legs, that the affection cannot be treated as a generic one. Each case will present certain peculiarities which require to be noticed, and, as the condition of the limbs may depend upon quite opposite states of the system, it is necessary to determine, previous to attempting a cure, to what causes the swellings are attributable. Upon this principle the owner of a horse, on being informed that the animal is suffering from swelled legs, instead of at once directing the administration of a dose of physic or a diuretic ball, will proceed to the stable, carefully inspect the patient, and minutely inquire into the details of his recent treatment. A number of circumstances will have to be considered. If the horse has been severely worked for the past few weeks, and has fallen off in condition, if the appetite is bad, the coat harsh, and the skin adherent to the subjacent tissues, it is evident that debility is the primary cause of the swelled legs, and on examining the enlargements they will be found generally to be dropsical in character. Should it appear that the animal's health is more decidedly affected, and indications of acute disease are present, the swelling of the extremities will be no more than one of the signs of general derangement, and will not, therefore, be the primary object of concern. When one limb only is attacked, and the swelling is hot and painful, a careful exam-

ination of the heels, and even the foot, should be made, to ascertain if cracked heels exist, or if there are any signs of grease or thrush, either of which may be connected with the tumefaction. The possibility of injury, such as a contusion or sprain, having occurred, must also be taken into account. None of these diseases being present, it will be fair to infer that the swelling depends upon the localization of a morbid state of the system. This case would be an illustration of what is termed the "humoury condition." It may be that the subject of the swelled legs is fat, and habitually inactive; in such cases the enlargement will be due to congestion or inflammation, to which the plethoric system is naturally predisposed. All these varieties of swelled legs will require local and general treatment adapted to the peculiarities of each individual case. Hence it must be apparent that the term "swelled legs," as applied to engorgement of the extremities, or any of them, is not in itself expressive of the nature of the disease, nor suggestive of a plan of treatment; and it is not improbable that the absence of discrimination in dealing with these affections, as though they all belonged to one class and could be cured by a uniform remedial method, is one cause of their frequent degeneration into a chronic form of disease which is incurable.—*The Field.*

Veterinary Queries.

A Correspondent submits the following cases for our opinion:—

"Can you account for the fact, that when gestation exceeds a year, foals seldom or never do well, while calves, under similar circumstances, are as strong as others?

"Please say what is the matter with a mare.—About two months ago she, along with three other horses, was turned out for exercise. Joining two year old colts, belonging to a neighbour, they ran about a good deal through the fields. In the evening she came home quite lame of the near fore leg, and resting the toe, but with no external marks of injury Thinking that the rest would restore her, we let her alone, but she limps now as bad as ever. In what part of the shoulder is the injury likley to be, and can any remedy be applied?"

Ans.—The usual period of gestation in mares is eleven months, and it is very rare that it extends over a year.

Judging from the pointing of the foot, we are of opinion that the lameness is not in the shoulder but lower down, probably within the foot. We would recommend you to have the mare examined by a competent veterinary surgeon.

The Dairy.

Milk and Dairies.

On the 2nd July last we had the pleasure of visiting and inspecting one of the dairy farms from which Messrs. J. & J. L. Burney, of 70½ Queen Street west, receive a large quantity of the milk with which, for the last year, they have been supplying the city of Toronto. The farm referred to is that of Messrs. N. J. Campbell and Brothers, situated in the township of Nelson and county of Halton, about three miles from the line of the Great Western Railway. The Messrs. Campbell were formerly engaged very largely in the manufacture of cheese according to the factory system, and had gained a reputation in that line. Latterly, however, having made arrangements with Messrs. Burney for sending them all their milk, they have given up cheese-making, bought a large number of first-class milch cows, which they have added to their former stock, and turned their farm, which consists of about 700 acres of good land, into pasture. The land is naturally well suited for dairy purposes. The pasturage is excellent, and a never failing stream of pure water runs through it. The Messrs. Campbell, intending, henceforth, to devote their whole time to the business of supplying the city with milk, through Messrs. Burney, have got all their arrangements put into the nicest order.

In the first place, all the water required on the premises is brought from the stream mentioned above. The water is by means of a force-pump connected with a water-wheel, which is placed in the stream and kept in motion by the current, raised through pipes to the height of 160 feet over a perpendicular bank. The piping is then continued for a distance of about half a mile, ending in a cistern in the building where the milk is kept. In this building there are two vats. One of these is a double one, the outer being formed of wood and the inner of zinc. The zinc part of this vat is so constructed that it is placed in the wooden part so as to leave a space of about four inches all round it. This space is filled with cold water, and, morning and evening, when the cattle, after having been fastened in an adjoining building, are milked, each pail is carried in and poured into a strainer extended across one end of the vat. The milk falls on the zinc bottom and runs slowly, by a gentle incline, down to the other end and through a tap into ten-gallon cans, which are ready to receive it. By passing slowly over the bottom of the vat, the animal heat is driven out of the milk by means of the cold water beneath the zinc. The other vat is built of brick and filled with ice water, into which the cans of milk are placed and allowed to remain, becoming further cooled, until the morning, when they are taken to a flag station of the Great Western Railway, and put on board a car for the city. After arriving in the city the milk is again put in ice-water, except such as is allowed to become sufficiently warm to raise cream. The cooling process through which the milk goes prevents the cream forming on the top, so that on looking in the morning, no sign of cream can be detected; but it remains distributed throughout the milk. It is evident, therefore, that milk cooled in this way is far richer than such as has not undergone this process. The Messrs. Burney have a similar establishment in the township of Trafalgar. They are about building a large reservoir at their establishment, in which they will keep a supply of water to be forced into it by means of horse-power, through pipes extending into the lake. The Messrs. Campbell also intend getting a steam engine for the purpose of cutting and steaming the food for their cattle during the winter. It will thus be seen that both these establishments are of a very extensive character. The Messrs. Burney are daily receiving over two hundred gallons of milk, one hundred and fifty of which are from the establishment of the Messrs. Campbell, and they intend to keep up the supply to their customers all winter. From a personal inspection we can assure our citizens that everything is conducted with a scrupulous regard to cleanliness.

This matter of receiving an ample supply of pure milk is receiving a great deal of encouragement from a large number of the medical men of the city, and the poor as well as the rich can avail themselves of the advantage, as it is sold at a price as low as the lowest in town. The arrangements described above were patented this spring by the Messrs. Burney, so that persons wishing to use them in any other part of the country will be obliged to purchase the right from them. There is another milk dairy in the township of Nelson, conducted in the same way by Mr. T. D. Harrison, who has the right for the County of Wentworth, and supplies the city of Hamilton.

☞ Francis Gowdy, of Vermont, says that he has a cow that gives forty quarts of milk daily. The fifth chapter of Acts contains a story that may be of interest to Francis.

Learned Pigs.—The Dayton (Ohio) *Journal* tells the following story of three learned pigs:—Wm. Huskot, who resides on Wayne Street, in this city, has a fresh milch cow which suddenly and unaccountably quit letting down her milk, recently. As the habits of the cow were regular and she did not go away from home far enough to get milked by parties who are given to that practice, Mr. H. could not account for the failure of the animal to yield her accustomed quantity of lacteal fluid. But he determined to find out if such a thing were possible, and set a boy to watch the cow. In the course of an hour or two, the boy had solved the problem. A trio of pigs, not half grown, approached the cow, one after the other, taking turns, and stripped her bag of milk. The milking was performed in a business sort of a way, rather gingerly, and the cow rather liked it. Mr. Huskot didn't like it, and took measures to prevent its repetition.

Irish Butter.—Once upon a time, and not so long ago either, Irish butter enjoyed a very enviable reputation in the market, but it has suffered exceedingly in public estimation owing to the practice of excessive salting, or "loading," as it is called by dealers, to increase weight. A butter factor was recently fined £2 by the Lord Mayor of Dublin for selling butter fraudulently made up. On being subjected to analysis it was found to contain in 100 parts: butter 62, water 5, salt 33—total 100. It is said that several pence per pound are now lost by Irish dairymen in the price they receive, owing to the degree in which confidence has been lost in the quality of the article they send across the channel.

Poultry Yard.

Poultry Culture.

In the course of the investigations conducted under the auspices of the British Society of Arts, with a view to augment the food supply for the increasing population of Great Britain, and especially of the metropolis and other large towns, an interesting paper was read before the Food Committee of the above society, by Mr. George Manning, on "Poultry Culture." The substance of his remarks is thus given in the *North British Agriculturist*:

"In looking for new sources and for the further development of the old means of animal food, I cannot but think poultry claims our attention before many others, as having once formed an important part of our meat supply, as being simple and inexpensive in culture, and everywhere ready to hand. Of late years, however, poultry has fallen into neglect; and this kind of meat can now be procured at such prices only as to render it an expensive luxury rather than a reasonable portion of daily food. The farmyard seems to be the proper home of the rasorial order of birds; yet it is here that the neglect is most evident, whilst farmers for the most part deny the usefulness of this portion of stock, and tolerate it only from habit. It is not only the farmer, however, who raises objections to this kind of food. The consumer has certain prejudices. On the part of the farmer it is said:—

1. That poultry stock does not pay.
2. That even if it did pay it is too unimportant to engage his attention.
3. That it damages the stackyard.
4. That it is injurious to the crops.

On the part of the consumer it is urged:—

1. That the retail price of poultry is such as to place it out of the list of daily foods.
2. That, even if it can be produced at reasonable prices, it is a poor substitute for butchers' meat, and does not contain sufficient animal nourishment.

If poultry-keeping does not pay, and under existing circumstances, in the majority of cases, it probably does not, the reasons are to be found in the following facts:—

1. That no attention is paid to the choice and management of stock.
2. That food is irregularly and wastefully administered to it.
3. That no regard is had to the roosting, and particularly to the laying places of hens.
4. That the demand is restricted by the market system.
5. That farmers' wives have ceased to be henwives.

With regard to the choice management of stock in poultry, we find on farms generally, mongrel-bred birds, which, from continued in-breeding, have deteriorated in size and stamina. The barndoor fowl of the olden time has changed, particularly within the last few years, becoming continually less useful for food. It is true that the barndoor fowl was always a mongrel; but when farmyards were the nurseries of fighting cocks, where landlords, by covenant inserted in the leases, required the tenants to "walk" a game cock, or number of cockereis, and tenant-farmers bred birds for the pit on their own account, there was a continued infusion of new and vigorous blood into the progeny of the hens that stocked the yard. That custom has happily nearly passed away. The deterioration, however, began by the loss of these high-bred cock birds. Again, when the fall and a careless system of farming made the barndoor a golden feeding-ground, chickens had opportunities of growth which they now have not, and which must be supplied to them more economically and judiciously by hand if rearing poultry is to be profitable.

This plan, however, has been neglected; for poultry, unlike other farm stock, has not only not advanced, but has gone back in value, and consequently in estimation. The average weight of barndoor fowls sold from farmyards is three and a half pounds. From this must be deducted three ounces for feathers and twelve ounces for offal before they become food. The game-cock, as bred for the pit, rarely exceed four and a half pounds; but by crossing with the Malay, they may be brought to six or seven pounds in weight. Dorkings, when not in-bred, but well and carefully fed as chickens, will reach to seven and a half pounds as pullets, and to nine pounds as cockerels; higher weights, such as ten pounds for hens, and twelve pounds for cocks, can be obtained, but these are exceptional. Dorkings, however, are not suited for cold clays and damp soils. Of food birds, besides Dorkings, the game and the large Surrey and Sussex fowls (which last always command a high price,) there are the 'Brahma Pootra fowl and the Houdan or French Dorking, well adapted for use. Of these the Dorking and Surrey fowls are beyond all question the best for the table, in delicacy and weight of flesh; the game the most savory, although deficient in size; the Brahma Pootra not so delicate in flavour as the others, but hardy, weighty, and easily fattened; the Houdan having the good without the bad qualities of the Dorking—precocious and small-boned, being non-sitters, and almost uninterrupted layers of large eggs. The Brahma Pootra seems to be a useful stock on which to build other varieties. Of these, the cross with the Dorking is most strongly recommended; and a cross with the Houdan produces table chickens of a fine size. At the last Chelmsford and Essex Poultry Show, the birds which took the first and second prizes for dead poultry, trussed as by poulterers, but not drawn, were, the one thirteen pounds twelve ounces, the other thirteen pounds ten ounces, the pair at five months old. They were the direct offspring of a Brahma Pootra cock bird and Dorking hens. For stock it would be a better plan to put a Dorking cock with Brahma Pootra hens, and the pullets of this union with Dorking cocks in no way related to the ancestors of the pullets. Very handy and weighty table birds may thus be produced. By answers to inquiries, and by reference to the books of a farm, including the last six years, I find that the average price paid by higglers for barndoor fowls of the average weights first mentioned, is two shillings for coop-fed, and one shilling and eight pence for yard-fed birds. The cost of feeding and rearing the prize birds at Chelmsford was probably very little, if at all, more than that of raising the others. With regard to feeding, our system of leaving chickens to shift for themselves until such time as they are ready or wanted for the coop, is all wrong. No attempt at after-fattening will increase frame if the feeding of infancy has been disregarded. Again, the indiscriminate emptying of apronfuls or sievefuls of grain in a heap on the ground, whilst it serves to gorge the powerful, leaves chickens and weaker birds to starve, picking up here and there a grain, whilst sparrows and small birds have a large share in the feast. I see that Mr. Mechi published last month the results of an experiment in the cost of feeding a single hen, shut up and without access to any food but that which was given by hand. The result shows that five pounds of barley at the average of one penny per pound (or forty shillings per quarter) will make one pound live weight of poultry food, worth nine pence per pound. I say it is quite practicable to feed poultry more cheaply, and consequently to sell them cheaper than shown by this method—that is supposing them to be at large; but I am sure Mr. Mechi will pardon me for saying that I think this statement of feeding in confinement is rather low, a circumstance which may arise from the fact that the bird pined at first. I have tried the same experiment with two pens of birds, consisting of a cock and two hens, confined for a long time to separate but very small wired pens. I tried it in March last year, and in the month just ended, and I found that my birds consumed three and a half pints to his two and a half pints in the week; but then I dare say the barley I used was of foreign growth, and of much lighter bulk. Birds having a free run would cost very considerably less. I must not occupy your valuable time with the details of what is necessary for the housing of birds, and for their places of laying and incubation. It will be enough to say that they should be, what they are seldom in farmyards, namely, cleanly, convenient, and attractive."

After the reading of the paper, further expressions of opinions were elicited by questions, in answering which, Mr. Manning said that he considered the nest should, if possible, be on the ground. He disapproved, as a general rule, of heating the fowl house by flues. As to the nutritive value of poultry meat, he thought it inferior to no other animal food. The objection that poultry damaged the stacks and crops was combated by the experience of Mr. Mechi and others, who found that the birds did a vast amount of good by destroying insects, which they preferred to the growing grain. This objection would also be obviated by a proper system of feeding. The tendency to epidemics amongst poultry kept on a large scale would, he thought, be prevented by the free use of lime and salt, great attention to cleanliness, and sufficient run for the birds, particularly a free access to the fields.

Poultry Disease.

"W. C.," from *Belleville*, writes as follows:—

Through the medium of your valuable journal I would like to get a little information. Two days ago ten of my little chickens, about a fortnight old, were suddenly attacked by a disease which killed them during the day. Later on some older chickens, and two eleven weeks old, and also an old hen, were seized with it and died. The symptoms seemed to be confined to a straggling, aimless walk at first, then a vacant look in the face, accompanied by a spasmodic gaping. Just before dying their struggles were very violent, all the limbs becoming quite rigid. They had plenty of water and nothing larger than buckwheat to eat, and, moreover, were running at large. Others in the hennery were not touched. A farmer living near calls it the "blind staggers," and says he has lost several in the same way. I tried bleeding in the case of the old hen, but without effect. After death I opened one of the larger chickens, and in the gizzard found what appeared to be the grub from a blue bottle fly, commonly known as a "gentle." I have lost some sixteen fowls altogether, and would like to know, if possible, what is the best remedy for the complaint.

Yours, &c.,

W. C.

NOTE BY ED. C. F.—The symptoms very much resemble those of poisoning. At all events the treatment we would recommend is the administration of a dose of jalap. One teaspoonful mixed with the food of twenty chickens would be the proper proportion. After which a tonic would be of service, which might be given by mixing with the drink of the fowl as much sulphate of iron as would make the water taste slightly inky.

Means of Knowing if Eggs are Fresh.

THE *Gazette des Campagnes* gives the following directions for testing the freshness of eggs:—

"We may observe, in the outset, that when an egg is fresh it is always full, that the shell is very porous, from which we draw the conclusion that in time a portion of its contents must evaporate, being replaced by a portion of air, which surrounds and presses the shell on every side. This air goes to the large end of the egg, because it finds there more surface than at the other end. Now, the liquid contained in the egg is a better conductor of heat than the air. If, then, the egg is fresh, the large end will be full of liquid, and we shall feel a sort of coolness on poising the large end in the hollow of the hand, because the liquid of the egg carries off a portion of the warmth of the hand. If, on the contrary, the egg is old, the air collected in the large end being a bad conductor, will not attract the warmth from the hand, and we shall not feel the coolness. It requires, it is true, a little practice and a certain delicacy of touch to avoid error in using this process, but that can be acquired much more promptly than may be imagined, and we have seen people capable of trying in this manner thousands of eggs without committing the slightest mistake, whilst the method of the *mirage* of the eggs by light gave deplorably fallacious results."

JOINT-STOCK NESTS.—My keeper, two days ago, found a nest containing seven pheasant's, three hen's, and four duck's eggs. The nest was some distance from the farmyard. Query, which made the nest? A week or two ago I found a pheasants' nest with thirty eggs in it.—*Field.*

Entomology.

Burying Beetles.

To the Editor of THE CANADA FARMER

SIR,—More than twenty-five years ago, I read, in *Chambers' Journal*, of Herculean feats of grave-digging beetles, but fail to remember anything at all of the description given of the beetles themselves. The enclosed specimen I (only) suspect must be one of them, through its performing a feat that perfectly bewildered me to account for. On Tuesday morning (June 16th), I was crossing a plantation of cabbages when I met quite a large-sized milk-snake, and because they have a bad character for sucking cows, I took its life by striking him at the back of the head with a pliant stick. He quickly died, bending himself to just about half his length, being fully a yard long. The place where he lay was between *two ridges*, and the ground was sandy. On passing that way next morning, I saw a large portion of the tail part was buried, and could see fresh earth being upheaved from beneath him. Next morning (Wednesday) I again visited the spot, and saw a large amount of work had been done. The head part (in length about eight inches) remained unburied, and was somewhat curved, and quite stiff. The ground below it was excavated to a considerable depth, and in form like the curve. And now, for the first time, I saw the performers; they both came out and walked on the top of the unburied part, and if I understood them aright tried (with their united weight) to press it down in the grave below; but this they failed to accomplish. On the score of humanity, I got a piece of clotted earth and pressed it down for them, and so left it covered. Excavations still continued till Friday morning, when they ceased. I now thought to leave them a while without disturbing them, but frequently took a look at the spot. No further change took place till Sunday, when the first thing I did after dinner was to stroll to this now interesting spot, when I saw one of the beetles having just emerged from below. He walked to and fro in a very undecided and awkward manner. At last he succeeded in climbing to the top of the ridge, taking a vacant stare, as though the world was new to him. His antennæ were about a quarter of an inch long, mounted with a tuft, something like a rosette. He now continued to comb with his brawny fore-legs (alternately) his antennæ, for about ten minutes, when the horny cases on his back began to move, and by slow degrees a pair of splendid gauze-like wings, which had been folded up in a very small compass by different hinges, made their appearance. I did not sufficiently suspect that he would really fly away and leave so much treasure behind, but, to my regret, he went off with a bound, with a melodic pitch to his wings, of about high C. I thought now I would like to know a little of the condition of the snake; and first I took up the rather large piece that I weighted the head part down with for them, and not doubting but that I should see it in nearly the same position as when I covered it; but no trace of it could I see, and concluded (with much regret) something had taken it away. I was about leaving, but thought I would just scratch a little more earth away, and found a place much softer, and carefully taking away the earth to about four inches deep, I found the other beetle in a torpid state, and swarming with very small but active and clean-looking insects. I took her out, and continued the search, when close by where the beetle was found, I discovered the mouth of the snake. I now found there was a round hole of about three inches in diameter and five inches still deeper. It was exactly in the following position:—Supposing a hole nine inches deep and three or four in diameter, and you took the dead snake (when quite limber), holding him by the head, then letting him down tail first in the hole, with his mouth perpendicular.

The beetle that flew away was much the largest. The one I send you soon died, being confined in a flower-pot.

Is this the veritable Grave-Digging Beetle?

Secondly. How did they put the snake in the position described above?

A SUBSCRIBER.

NOTE BY ED. C. F.—The insect referred to in the foregoing graphic description is a specimen of the veritable Sexton, or Burying-Beetle (*Necrophorus Marginatus*, Fabr). The snake was probably placed in the position referred to by being gradually undermined in the direction of the head, until the tail was brought directly beneath it; had the beetles been left alone a few days longer, they would probably have sunk the snake much deeper in the earth.

We have often observed similar performances by these beetles, which are very curious and interesting. At the very time we received this communication we were watching the interment of the dead body of a toad, which had been accidentally drowned. We left it lying on a sandy piece of ground; two days afterwards it had been removed to the distance of a foot from its first position, and had only its hind feet sticking up in the air, the head being downwards; the labours of the beetles underground caused it to move about, and look as if it were diving into the sand, just as one sometimes sees the tail and feet of a duck sticking up above the water of a shallow pool, while their owner is seeking food at the bottom. Two days later the toad had quite disappeared. On digging with a trowel at the place where the ground had been last disturbed, the soil around being slightly crusted, no toad was to be found! We continued to dig, however, around the spot, and at last found the toad six inches below the surface, and about the same distance from the place where we had last seen his legs; the surface of the ground immediately above him being perfectly undisturbed. In this case also the gravehad been dug in an oblique direction, and not directly downwards. Underneath the body we found the two Sextons—specimens of another species of the same genus of Beetles (*N. Orbicollis*, Say), which can be recognised from the annexed figure. There are at least ten species of

these grave-digging beetles in Canada, differing from each other in ornamentation and structure, but all possessing the same habits and instincts. Their office, though loathsome, is pre-eminently useful, it being their duty to remove from the surface of the earth the dead bodies of animals which would otherwise soon become offensive and injurious to health. After they have buried a carcass the female deposits her eggs in it, which speedily hatch, and the larvæ at once set to work to devour the dead and putrid matter.

Dr. Hall's Curculio Catcher.

To make a "Curculio Catcher," we first obtain a light wheel of about three feet diameter, the axle-tree of which should be about ten inches long. We next construct a pair of handles, similar to those of a common wheel-barrow, but much more depressed at the point designed to receive the bearings of the axle-tree, and extending forward of the wheel just far enough to admit a cross-beam to connect the two handles at this point. Directly in the rear of the wheel a second cross-beam is framed into the handles; and two feet further back a third. The two last named beams have framed to their under side a fourth piece, say two or three inches in diameter, which is placed centrally between and parallel with the handles.

To the handles and to these last named pieces, our stretchers to support the canvas are to be fastened. The front part of the beam, connecting the handles before the wheel, is designed for a ram, and should be covered with leather and stuffed with furniture moss, a dozen or more thicknesses of woollen cloth, or other soft substance; care being taken to use no more than is sufficient to protect the tree from bruising. The frame of our Catcher being finished, we next ascertain the elevation the handles should have in driving, and support them in that position. Having ready twelve stretchers or arms, (six for each side,) which are to receive and support the canvas, we place the long front arms in position. These extend from near the centre of the wheel on each side, and beyond the wheel in front about six feet; and are wide enough apart to receive the largest tree between them, on which it is intended to operate. The remaining stretchers are supported on the handles, and attached to the cross and parallel pieces in the rear of the wheel. These are so placed as to divide the space at their outer ends equally, between the first-mentioned stretchers and the ends of the handles.

We now have ready a strip of board, one-halfinch in thickness and two and a half wide. One end of this is firmly secured to the forward end of one of the front stretchers; it is then secured to the end of the next, and in like manner to all the others on one side of the machine, and fastened to the handle. Both sides are made alike. The office of these two strips is to hold the outside ends of the stretchers in their proper position, and prevent the two front stretchers from closing. These outside strips also receive the outside of the canvas, which is fastened to them, as well as to the several arm supports. Three of these arms, on each side, may be cut and hinged so as to fold up, thus making the machine more convenient for housing. In this case two additional sets of braces would be required, and each of the outside rims would be made in three parts, instead of one, as first described.

From the description thus far given, it will be seen that the wheel occupies a central position, and is nearly in the centre of the machine. To avoid an opening at this point, a frame is fastened to the handles on either side of it, and brought together over the top of the wheel. This, as well as the stretchers, is to be covered with canvas. The arms or stretchers are so curved, that the jarring motion in moving from one tree to another brings everything falling on the canvas to the most depressed points, where openings are made into tunnels, to the ends of which the mouths of pockets or sacks are tied. These can be removed from time to time, and their contents destroyed by immersion in hot water. The whole machine, when completed, is about 10 feet in breadth by 11 or 11½ long; or at most 11½ wide by 13 or 13½ feet long. These are for large orchard trees. Smaller trees could be protected with a smaller machine. The frame-work, when covered, should be so nicely balanced, as to require scarcely any lifting to hold it at the proper elevation.—*Dr. Hall's Essay on the Plum Curculio.*

Insect Specimens.

WE have received from Mr. J. M. Bristol, of Virgil, County of Lincoln, Ont., a very interesting specimen of a Snout Beetle or Curculio; it is about half an inch long, of a shiny black colour, covered with yellowish down, or short hairs. The species is quite new to us, and we have not been able to find it in any Canadian collection that we have access to; of course we have not the least idea upon what the insect feeds, or what is its natural history. Being so rare it cannot be considered injurious; we shall, however, endeavour to find out all about it.

We have also received two specimens of the large eyed spring-back beetle (*Alaus oculatus*, Linn.). Though it belongs to the dreaded family of wire-worms it may be considered as non-injurious, its favourite food being decayed wood. We have had another fine specimen of this insect sent us by Wm. Magrath, Esq., Erindale, Credit.

☞ A raid upon cockchafers has lately been made around Paris, especially in the Bois de Vincennes. More than 15,000 litres have been killed. The trees are shaken in the morning early when the insect is in a state of torper and easily detached. Collected immediately, they are thrown into tar water from the gasworks. This liquid kills them almost instantaneously. They are afterwards used as a manure. This "raid" is simply a result of the wholesale destruction of insectivorous birds that has been going on for several years in France, and should be a warning to the promoters of "sparrow clubs," and destroyers of crows, &c.

THE GRASSHOPPER PEST.—The Chicago *Post*, June 19th, says:—The grasshopper plague is devastating Western Iowa in a fearful manner. A friend who has just come in from Sioux City, informs us that of about one hundred and fifty miles wide, extending from south western Dakota—chiefly between the Des Moines and Missouri rivers—to the southwestern boundary of Iowa, there will be scarcely a wheat field left exempt from total destruction by these vermin. They fill the air and cover the ground, making a constant sound like that of a heavy shower. They sometimes gather over night in such myriads upon the track of the railroad as *to stop the train* by lubricating the track when crushed by the wheels. They devour wheat first, and afterwards take to oats and weeds, leaving grass and other crops comparatively unharmed.

SCARLET SPIDERS.—"One of our Readers" sent us the following note with the specimens therein mentioned. "The enclosed beautiful little scarlet insects we find crawling about on the ground, apparently very happy, and glittering like coral dust in the sunshine. We are curious to know the name and economy of these brilliant little creatures."

NOTE BY ED. C. F.—The tiny coral-red specimens are diminutive spiders, whose avocation, no doubt, is to destroy even tinier flies and other insects; we found them ourselves very early in the spring, and repeatedly since, in the sandy soil of our garden. They are exceedingly pretty little creatures, and probably useful as well; we do not know their name, but they are quite different from what is known as "the Red Spider," a tiny ground mite that is often troublesome in hot-houses, injuring vines and plants by spinning fine webs over their leaves.

DOES FROST KILL LARVÆ?—In a paper addressed to the Academy of Sciences by M. Reiset it is distinctly stated that the general belief held by agriculturists, viz., that severe frost kills noxious insects and larvæ that grub in the earth, is a fallacy. This proposition led to a discussion amongst the members of the learned body. M. Emile Banchard, after doing justice to M. Reiset's important researches, said that it would be wrong to suppose that naturalists had hitherto lived in ignorance of the habits of larvæ feeding on roots, and that it was a well-known fact that, while the temperature continued mild, they remained near the surface, and on the contrary descended to greater depths as the cold became more intense, so as always to escape the effects of frost. The idea, therefore, that a severe winter would rid agriculture of its greatest enemies, was utterly without foundation. M. Chevreul said that M. Reiset had no intention of passing himself off as the discoverer of the fact alluded to, but had done science a great service by instituting precise experiments for the purpose of ascertaining at what depths, according to the temperature, larvæ would be found in the soil, and this had not been done before. These experiments had been carried on for upwards of a year, and M. Reiset had ascertained that while the thermometer stood at 15 deg. cent. below freezing point in the air, the temperature of the soil at a depth of 50 centimetres did not fall below zero; this happened, however, on an occasion when the ground was entirely covered with snow. After these important experiments M. Reiset had told agriculturists that they were utterly mistaken if they trusted to frost for the preservation of their crops from insects, and that they must exert themselves if they wished to rid themselves of the impending scourge. In this M. Reiset had done his duty, without raising any pretensions to a discovery. Last autumn M. Reiset, knowing that the white worm was still quite near the surface, caused a field to be slightly ploughed and harrowed; two women followed the harrow with baskets, and collected 344 kilog. of white worms, at a cost of 12fr. per hectare (2½ acres.) This field produced an excellent crop, while that next to it, which had been let alone, produced nothing.—*Galignani.*

The Plum Curculio.

To the Editor of THE CANADA FARMER:

SIR,—I send you half a dozen of what, by the description given by "Fruit Grower" in the CANADA FARMER of the 1st June, I take to be that abominable pest, the Curculio. I have carefully followed the plan adopted by "Fruit Grower" and have succeeded in destroying some three dozen. I may add that I consider his method the only one worth anything. The "binding of rags saturated in oil round the stem of the tree, and the subsequent use of chloride of lime and sulphuric acid, I have proved to be utterly useless. I am persuaded, if this be the "Turk," that "Fruit Grower's" remedy is thoroughly efficacious, and would venture to recommend it to all who at the "bloom" expect a good return, and at the gathering are sadly disappointed.

I have found white *hellebore*, used as recommended in a late number, an effectual destruction to the gooseberry caterpillar. A small teacupful well mixed with a little water will make a paliful; this I applied with a watering pot, chiefly in the centre of the bush, in the early spring, just when the leaves appeared, and I have not one caterpillar, whilst the garden the other side of the fence is swarming with them.

J. F. BROWNE.

Toronto, June 25th, 1868.

NOTE BY ED. C. F.—The specimens sent us were genuine "Little Turks," or Plum Curculios. We append illustrations of the insect magnified, (figs. 1

and 2); a punctured plum, (fig. 3); and the Curculio at work, (fig. 4). These figures, with the description

we gave in our last number, will, we trust, enable any one to recognize the enemy without difficulty. Bandages round the stem of the tree could not be of any use in keeping off the Curculio, because it flies with great activity, and does not require to climb up the trunk: but when properly applied they are effective remedies against the parents of the Canker Worms, (*Anisopteryx*,) which come out of the ground, and in the female sex are destitute of wings. We are glad to find that Mr. Browne has tried the jarring process, and has found it useful; we believe it to be the only efficacious remedy.

☞ From all parts of the South and Southwest come direful accounts of the appearance of the seventeen year locusts, as they are popularly called, though they are in reality a very different insect from the locust, and should be called the Cicada.

Correspondence.

Farmers' Clubs.

A CORRESPONDENT from Seneca, in Haldimand County, applies to us in reference to the organization of "Farmers' Clubs." "As we are about," he says, "to organize a Farmers' Club for this locality, and as I am inclined to think there are some prescribed rules for the government of such clubs, I therefore write to ask you to assist us by sending me a copy of the rules, if it is convenient for you to do so."

Not having any such document at hand, and knowing that the Herkimer Farmers' Club, in which Mr. Willard, if not an officer, takes a lively interest, was one of the most successful institutions of the kind, we wrote to that gentleman asking him to forward us the rules of the Society, if they were printed. The discussions of this Club are frequently reported in the *Utica Weekly Herald*, and are full of interest, and often elict very valuable information. Mr. Willard very kindly and promptly replied, expressing his regret that, as the Constitution and By-laws of the Club were not printed, and he did not happen to have them at hand, he could not comply with our request, adding, however, that "the By-laws are of the simplest character, they merely rehearse the duties of President, Vice-President, Secretary and Treasurer. A fee of one dollar is required for membership. Discussions are held twice a month. The discussions are informal, members keeping their seats and talking—giving their experience—asking and answering questions, &c. We find this plan results in obtaining most information, as many farmers can not be induced to rise and make a set speech. It is preferred that the member appointed to open the discussion write out his remarks. Some do, and others do not."

We do not know that we can add any particular directions for the guidance of our correspondent. The constitution and rules generally state the name of the club, its objects, and its management. The objects are, to promote social intercourse among the farmers of a neighborhood, and give them an opportunity of comparing their experience, and thus adding to the stock of agricultural knowledge. This is done by meetings held at regular periods, especially during the leisure months of the year. The frequency of the meetings must, of course, depend upon local circumstances. The duties of the officers are few and simple—the office is usually held from year to year. An annual general meeting is held to elect officers, receive the report of the year's proceedings, and the Treasurer's financial statement, and to transact such other business as may be required. The regular and ordinary meeting should be made as pleasant and social as possible, but not, to our thinking, by the aid of tobacco and whisky, as we saw gravely recommended not long since in one of our exchanges. If the Club is made the means of taking the farmer from his own fireside to the ale house, it will be more mischievous than beneficial. We commend the example of the Brighton and Cramahe Farmers' Club, several of whose meetings are attended by ladies, who evince considerable interest in the proceedings, and must have a very beneficial influence upon the character of them. In the number of the CANADA FARMER for Feb. 15th, 1867, is a report from the Secretary, Mr. J. C. Squier, of the proceedings of the above Society. We should be glad to receive similar reports, and if any established Society would furnish us with a copy of their rules, they would be of service in answering enquiries like those of our correspondent.

GOAT WANTED.—A subscriber from Limehouse enquires:—"Can you or any of the readers of your journal inform me, through your columns, where a goat or two could be purchased, as near the township of Esquesing as possible, and at what price?"

Bath and West of England Society's Show, &c.

To the Editor of THE CANADA FARMER:

SIR,—During the past three weeks I have had many opportunities of attending exhibitions, fairs and markets in different parts of England; a few remarks in relation to some of which may not be devoid of some interest to your readers.

The Bath and West of England Society is among the oldest established in Britain, dating its commencement from 1777. It embraces objects similar to those of the Provincial Association of Upper Canada, making agriculture a primary, without its being an exclusive object, and affording encouragement to arts, manufactures and commerce. The show was held at Falmouth, being at the extreme Western point of the kingdom, a circumstance sufficient to account for the smaller number of entries in each of the departments, as compared with previous years and more favored localities. Notwithstanding this drawback, the *quality* of the stock, implements, fine arts and manufactures is said never to have been exceeded, and the weather being most favorable, the attendance was very satisfactory.

In this part of the country the Devons would naturally occupy the most prominent position, and the display was really very fine. The Devon is certainly a small animal compared with either the Short Horn or the Hereford, but for beauty and symmetry of form, as also for quality, it can scarcely be excelled. There is a decided difference both in size and expression between the true North Devon, occupying a high and broken range of country, and those of the richer plains of the South and East, the latter being larger and mostly somewhat coarser. I saw an extensive herd of Devons, comprising the largest animals that ever came under my observation, belonging to Mr. Stuckey, near Taunton, in Somersetshire. They have excellent points, denote careful breeding, and possess excellent constitutions. The Short Horns were much less numerous, but in point of quality decidedly good, and the same remarks will apply to the very fine specimens present of Herefords. I felt a little disappointment at not seeing any specimens of the ordinary cattle of this interesting section of England. In sheep, however, the local breeds, mostly horned, were well represented; the Dorsets and other varieties are certainly very pretty animals, some of them larger than I was prepared to find them. The Leicesters and Cotswolds were not very remarkable, but the Downs were excellent. The horses both for the saddle and draught appeared to be above par; the farm animals being evidently well suited to the requirements of the soil, and the local wants of the district. The Exmoor ponies are small, hardy and free-working creatures, very useful for many purposes, and they are to be found more or less through the adjacent counties. The pigs were good, but not better, I think, than what we are accustomed to see in Canada on such occasions. Some specimens of the Lincoln breed, sent from that county, were certainly extraordinary for early ripeness and beauty of form. The Poultry department was exceedingly meagre. The large floral tent was well filled with exotics and flowering plants of much excellence. With the exception of ripe cherries and strawberries there was no fruit on exhibition, and no attempt made at a display of early vegetables, for which this district stands pre-eminent. In various parts of the Cornish coast large belts of land are put under cultivation for the raising of various kinds of garden produce, and many thousands of tons are sent by rail to London and the northern towns, which are supplied with cabbage, cauliflower, peas, rhubarb, asparagus, &c., several weeks earlier than they could be from their own localities. Sea-weed and sand, the latter consisting largely of comminuted shells, with carbonate and phosphate of lime, are extensively employed for manuring purposes.

The display of implements, &c., considering the remoteness of the situation, was very good, several of the principal manufacturers being represented. There was nothing particularly striking or novel in this department, but to a stranger the improvements made in recent years are strikingly apparent. The two halls devoted to the fine arts and manufactures were well filled, chiefly with original contributions, many of them of great merit, from various parts of this western section. I may just observe that a dog show was held outside the Society's grounds, comprising about 400 specimens of the different breeds, varying in size, forms and habits, in a most extraordinary degree. The race among half a dozen lifeboats in the channel could be distinctly seen from the grounds, which for natural beauty and adaptability to the purpose, far exceeds anything I have yet seen in any part of the world.

The Horse Show at the Agricultural Hall, Islington, was an eminent success. There were hundreds of animals, many of them of first-rate excellence, of all breeds, competing in various ways in well-defined classes with each other, with the exception, perhaps, of draught horses. The Hunter classes were decidedly good, better, it was said, than had ever appeared in this place before. The Arabs, too, excelled; such splendid specimens of this noble breed I never before witnessed. Hacks, roadsters, ponies of almost every description, appeared in great numbers, and to all lovers of the horse the sight must have been magnificent. The immense building was erected a few years ago for the accommodation of the Smithfield Cattle Show, but it is used for similar purposes at different periods of the year. The show of implements and machines, manures, &c., was of itself well worth a visit. The order and systematic attention to details through all the proceedings must have commanded the highest admiration.

I had an opportunity of attending the annual exhibition of the Hunts and Bucks Agricultural Society, held in the ancient city of Winchester. The show was not so large as I anticipated, but there were many good specimens in the different departments, few, however, worth particularizing. The Hampshire Downs appeared to great advantage, as the Sussex and Shropshires, Leicesters and Cotswolds were by no means up to their usual mark. There can be no doubt that the Down, in some of its varieties, is naturally best adapted to the high chalk pastures of this part of England, but on the heavier and richer soils the long-wooled breeds are the more profitable. The cattle and horses called for no particular remark, but the display of poultry was really magnificent, exceeding both in quantity and quality anything of the kind I have ever seen.

It is worth mentioning that I have now been travelling six weeks through several of the midland, southern, and western counties of England, and up to the present date have not experienced a single shower of any importance. A few thunder showers have occurred in some places, but generally the weather has been almost unprecedentedly hot and dry, with no immediate prospect of a change. The hay crop is mostly light, but cured in excellent order. Wheat is in bloom, and gets through the drought the best of any crop. It is in some places thin on the ground, and anything but luxuriant. It may, however, come up to an average. Spring grain of all descriptions must be light, and turnips, mangels, &c., unless the weather changes soon, must prove a failure. Hops are universally good. Grass being deficient, all kinds of live stock meet with a heavy sale, and graziers are experiencing great losses. All are heartily wishing for rain.

GEO. BUCKLAND.

Basingstoke, June 19th, 1868.

"Dry Earth System &c."

To the Editor of THE CANADA FARMER:

SIR,—A great deal has been said and written lately of Revd. H. Moule's "dry earth system." Can you or any of your readers inform me how the plan can be worked in this climate, as it is next to impossible to obtain fresh supplies of dry earth from October until June? A most valuable manure is in almost every case thrown away for want of some economical system of management.

2nd. Which is the simplest plan of burning clay for manure?

3rd. Not having been trained as a practical farmer, and having frequently had fields of grain ruined through carelessness in the man sowing—can you tell me of any inexpensive implement which can be used for sowing grain?

NOVA SCOTIA.

June 6th, 1868.

NOTE BY ED. C. F.—Those who have adopted the "dry earth system" in this country do not experience any difficulty in carrying it out. They collect their supply of dry earth in August and September, and store it in any convenient place. A barn will do; a cellar might be preferable. It is of the greatest importance that the earth should be perfectly dry, its efficacy depending principally on this condition; a sandy loam is the best kind for the purpose.

The plan is found in practice to be perfectly inexpensive and cleanly, counteracting all offensive odour, and furnishing a most valuable manure, which proves beneficial to almost any kind of crop.

In reference to the second question, the following extract from a lecture by Mr. Mechi may supply a hint:—

"The physical condition of the soil is entirely changed by burning. The bird-lime, or putty-like soil, previously almost impervious to air or water, becomes loose and friable, permitting the free circulation of plant roots, and making the land work so much easier, and leave the plough bread readily There is no safer investment on stiff clays than burning the sticking, dense, unmanured subsoil—where coal is dear it must be dried by the atmosphere before burning, and is of course summer work. One old stump of a Pollard will start and burn 140 cubic yards. The most notable and successful instance of earth-burning on a large scale is that of Mr. Randall, near Evesham. He has continued burning, winter and summer, for twenty years. Coal-dust is there very cheap, and one ton will burn twenty tons of earth."

With regard to the last query, our correspondent would doubtless find advantage in the use of a seed drill. Almost any of the agricultural implement makers furnish them. Messrs. Maxwell and Whitelaw, of Paris, manufacture a thoroughly good implement for the purpose.

The Canada Farmer.

TORONTO, CANADA, JULY 15, 1868.

The Weather and Crops.

IT is now quite safe to speak pretty confidently in regard to the season of 1868, as most of the crops are so far advanced as to be secure from injury, and it would be hardly possible to paint too glowing a picture of the promising state of things that prevails, with scarce any exception, from one end of the country to the other. The weather, with the exception of the recent heat and drought, has been all that could be desired to bring on crops of all kinds. Of late, gardens and field roots have suffered from the dry, hot weather, but the turnips are unharmed, and will start vigorously so soon as we have showers. There is an abundant yield of hay, and it is well cured. Haymaking is about over, and wheat harvest has fairly begun. We hear very favourable accounts of the wheat from various quarters. There is but little complaint of midge, and a very intelligent Vaughan farmer with whom we have conversed, is quite satisfied in his own mind that this insect pest is "played out," as the boys say. He is convinced of this, not only because of the limited depredations noticed the present year, but also because he believes the long-hoped-for parasite has come. At the usual time for midge, instead of it, a strange fly of the ichneumon class hovered about his evening lamp, and this he has little doubt is the midge destroyer, "long looked for, come at last!" Myriads of voices will respond, "so mote it be!" Spring grains look well. The dry weather has checked the tendency to an over-growth of straw, which was apparent earlier in the season, and if not too long continued will be favourable to the filling of the ear. Potatoes will be a light crop, unless the latter part of the summer should be wetter than the early part has been. Fruit still promises well, though there is much complaint of insect ravages in the orchard and garden.

British Versus American Farming.

OUR able Scottish contemporary, *The Farmer*, in a recent article on "the Grain-producing States of America," institutes, apparently without intending to do so, a series of comparisons between the styles of farming in vogue on the Eastern and Western sides of the Atlantic, which by no means redounds to the credit of trans-Atlantic agriculture, and the mention of which may perhaps act as a stimulus in quarters where that sort of influence is needed. After adverting to the enormous aggregate yield of wheat in the far-west, *The Farmer* observes:

"We do not at present wish to enter upon the discussion of the character of these soils and the manner in which crops are grown and harvested; but this we may remark, that the soil is of course virgin and rich, that 99 per cent. of the farming community are in total ignorance of scientific agriculture, that the air is innocent of the smell of guano, and broken British weather seldom worries the life of the prairie farmer as he reaps his autumn yield."

Here are found points in which it is either stated or implied that the new-world farmer appears to a disadvantage as compared with the old-world farmer. 1. Inferior tillage of a soil virgin and rich. 2. Ignorance of scientific agriculture. 3. Neglect of manuring. 4. Poor improvement of splendid harvest weather. Our contemporary feels assured that though the British farmer has to some extent a rival in the western grain-grower, he has not much to fear from such rivalry, and when the farmers of Britain cannot compete, and that remuneratively, with proprietors of small holdings in the far-west, "the sooner they turn to some other occupation, the better for themselves and the agricultural world." The grounds of this assurance are the scientific and systematic farming practised in Britain, comparative command of labour, use of improved machinery, artificial manures, and a ready market. *The Farmer*, waxing warm with his theme, indulges in a glowing and eloquent peroration, which more forcibly than any other portion of the editorial in question rebukes the short-comings of trans-Atlantic agriculture, while it betrays a pardonable if not justifiable pride in view of the comparative certainty to which the science of agriculture has been brought in the old world.

"The East-Lothian farmer, who can enjoy the pleasure and deep satisfaction of viewing the level field of full-eared wheat, swaying in the undulating waves beneath a bright sun, giving to the grain a last golden tinge before the reaper enters on its clattering work, can almost to a nicety tell you that he will thrash from that field his fifty or his sixty bushels an acre. And so long as he can do that, with even a tolerably high rent, he is able to set at defiance all the competition of the Baltic or Black Seas, as well as the not less formidable rival of a young western world, where many will perhaps be astonished to learn that the average yield per acre, over the whole wheat-producing breadth, is only about fifteen bushels per acre."

The homily to careless agricultural sinners, of which we have given in the foregoing paragraphs a few "heads and points," carries its own lesson without need of application from us, yet we cannot forbear a remark or two. It is undeniable that farmers in the United States and Canada are far outdone by their British brethren. With a soil nearly in its native freshness to till, we grow but a small average to the acre, and with magnificent harvest weather, we do not excel in the quality of the grain we produce. We are beaten mainly because old-country farmers give the land better tillage, and more manure than we do. Drainage and repeated deep ploughing, weeding, loosening of the soil, to-

gether with unstinted use of natural and artificial fertilizers, are the characteristic points of excellence in British agriculture, and of defect in ours. For want of acquaintance with the scientific principles which underlie their calling, too many among us have a prejudice against high farming, and fear to venture upon outlays which are in truth essential to great success. Here and there are to be found those who from want of capital are unable to farm better, but we have multitudes of farmers who have made money by pursuing a system of exhaustive agriculture, and who would rather let out their gains at eight per cent., or tie them up in an old stocking, than they would invest them in land improvement, well-bred cattle, or labour-saving machinery. The probabilities are that we shall go on thus until small holdings no longer yield even a meagre subsistence to their proprietors, and then capital will come in, convert a multitude of small holdings into a few large estates, and after some outlay in land improvement, astonish the natives by doing what the "East Lothian farmer" is doing to-day, namely, surveying in the golden radiance of the July sun "level fields of full-eared wheat," good for fifty or sixty bushels an acre when the reaping and threshing machines come to do their work. With an equally fertile natural soil, no rents, hardly any taxes, the best of agricultural implements at command, a climate unsurpassed for grain-growing, and only the one drawback of scarce and dear labour, we ought not to be so far behind the British farmer in actual achievement, as truth compels us to confess that we are.

The Wool Market.

THERE has been a good supply of wool the present season, but as was to be expected, prices have been moderate, and there has been no speculation. The business has been chiefly done by local buyers on their own account, and in changing hands purchasers have only looked for a fair commission for their trouble and risk. The market opened at about 25 cents, and in some instances, we believe, even a cent or two less. It has not advanced beyond 28 cents so far as we are aware, and perhaps 26 cents has been about the average. Low as these prices are compared with what has been realized sometimes of late years, they are better than some of the United States flock-masters have obtained, even with the aid of high protective tariffs, as will be seen by a paragraph elsewhere in this impression. A few American buyers have been in the Canadian market in order to purchase the long combing wool, which they require for their worsted manufactures. A certain quantity of long wool they must have, at any price, tariff or no tariff. The *Trade Review* says there is marked improvement in the quantity of Canadian wool. It is better washed, better put up for market, and there is a less proportion each season of dirty and "burry" wool. This is gratifying.

Notices of Books.

A GUIDE TO THE STUDY OF INSECTS, AND A TREATISE ON THOSE INJURIOUS AND BENEFICIAL TO CROPS.—For the use of Colleges, Farm-schools, and Agriculturists. By A. S. Packard, Jr., M.D., Salem: Press of the Essex Institute. Part I., June, 1868. Price 50 cents.

THE BUTTERFLIES OF NORTH AMERICA: with colored drawings and descriptions, by Wm. H. Edwards. Philadelphia: The American Entomological Society. Part I., April 1868. Price $2.

TRANSACTIONS OF THE AMERICAN ENTOMOLOGICAL SOCIETY. Philadelphia: Printed by the Society, Volume I., number 4, January 1868. $3 per annum.

Nothing can better attest the progress that is now being made on this Continent in Entomological science than the simultaneous publication of three such serials as those whose titles are given above. Twelve years ago, when we began the collection and consequent study of Insects, we were for some time unable to procure any works on American Insects except Gosse's Canadian Naturalist, and a few scattered papers in the Canadian Journal. By and by we succeeded in *borrowing* copies of Harris' Injurious Insects, Say's American Entomology, and Emmon's Insects of New York. These were very difficult to obtain, the two former being out of print, and the latter much more costly than it was worth; and these, with the exception of numerous papers scattered about in divers scientific periodicals, very expensive and not easily procured, were all the Entomological works extant in America. Soon, however, the Smithsonian Institution commenced its valuable series of publications on this branch of Natural History, and gave an immense impetus to the study of Entomology; and now we have magnificent reissues of Say's and Harris' works, and the press begins to teem with practical reports from State Entomologists, proceedings of Societies, lively popular papers in Magazines, and no end of articles and paragraphs in Agricultural Journals. A striking type of all this improvement is presented in the works before us, to which we now desire to draw the attention of our readers. We have placed them in the order of popularity in their intention, rather than in the order of merit, as they do not admit of comparison in the latter quality—all three being thoroughly excellent in their several ways.

Dr. Packard's *Guide* is a work which we trust will find its way to all who take any interest, scientific or practical, or both, in the world of insects. It is designed to assist the student in learning the structure, transformation and development of insects, to direct him in their collection and preservation, and to help him in the identification of his captures; it is also intended to afford a useful account of those classes of insects that are especially injurious to vegetation, and at the same time draw attention to those that are beneficial. The name of the author, whom we have long known and esteemed as a thorough Entomologist, is a sufficient guarantee that the work will be faithfully carried out. The part before us, which consists of sixty well-printed pages, and more than that number of accurate illustrations, presents us with a concise and clear description of the whole anatomy of insects, and begins to trace their transformations from the egg state. This will be completed in the next part, which will also contain notices of the Geographical Distribution, Geological History, and Diseases of Insects, with a list of the chief works on Entomology, and directions for collecting and preserving specimens. Subsequent parts will treat of special groups of insects, and afford much useful information in a popular manner. The first parts are necessarily of a less generally interesting character, though very valuable for all who desire really to study insects, and learn their actual nature. We can most cordially recommend the work, and wish the enterprise every success.

The next work on our list—Mr. Edwards' Butterflies—is of a most beautiful and sumptuous character, being fitted to adorn the drawing-room table as well as delight and assist the student in his closet. The part before us contains life-like and life-size figures of five different species of Butterflies, all of the genus *Argynnis*—popularly known as Fritillaries or Silver-spots. The drawings are most exquisitely done, and beautifully colored, and must delight even those most insensible to the loveliness of nature, and her gay animated flowers. While it is a work that appeals to the wealthy patrons of literature for its support, it is yet one which the Lepidopterist can hardly afford to be without; its publication at intervals of three months prevents its cost proving too serious an outlay.

To the remaining publication it is hardly necessary for us to draw attention; the Transactions of the American Entomological Society have been so long known and highly esteemed under their former title of the Proceedings of the Entomological Society of Philadelphia, that they need no words of commendation from us. They are designed, of course, only for the student of Entomology, and would prove almost unmeaning jargon to those who had not already mastered the rudiments of the science; to Entomologists, however, who desire to keep up with the progress of their favourite pursuit, they are an absolute necessity. The present number, which completes the first volume of the new series, contains descriptions and figures of several new species of Canadian Lepidoptera, amongst these of a large number of insects from all parts of North America.

Of Entomology, as well as of other sciences, it may now be truly said that its course is "onward, ever onward." What is its goal to-day is its starting-point to-morrow, and soon is left far behind!

DISCONTINUANCE OF THE "FRUIT CULTURIST."—The useful and ably conducted Horticultural Journal which has been favourably known by the above name, will, we are sorry to learn, be discontinued after the present month. In its place subscribers will receive the *Journal of the Farm*. We shall miss the welcome visits of the *Culturist*, which has been one of our much-valued American exchanges.

Agricultural Intelligence.

Traction Engine.

THE new Traction Engine recently consigned to Mr. W. Sutherland Taylor, by the makers, Messrs. R. Garrett & Sons, Leiston Works, Suffolk, England, was exhibited in practical operation on the streets of Toronto on Tuesday afternoon, July 7th. The success of the experiment demonstrates, as far as any ordinary judgment can anticipate results, the adaptability of the machine for practical purposes in this country, and the many different forms of labour to which it could be put, were suggested forcibly by seeing it work. The Engine was attached to two trucks loaded with seven tons of cast iron pillars from the foundry of Messrs. Hamilton & Son, Palace Street. In consequence of the trucks ordinarily in use with such machines not being ready, those belonging to Messrs. Sheddon & Co., Grand Trunk teamsters, were used, and after being filled with iron were loaded with an additional cargo of men and boys, the iron being completely hid from sight by the number of the aspirants after a free ride behind this novel mode of locomotion. A third waggon was also put into requisition, and filled with between forty and fifty people, and with this load—in all between twelve and fourteen tons—the engine started along Palace and Front Streets at a pace of about four miles an hour. This was accomplished to the utmost satisfaction of all the spectators, among whom were gentlemen from the neighbouring counties and at a distance, who had come to town specially to see the test made. The streets through which the novelty passed, were also lined with large numbers of people who evinced a lively interest in the proceedings. The powers of the engine were fully tested in ascending and descending even steep grades, and also in turning with its line of trucks in comparatively confined space. The engineer also showed, by stopping the engine in the middle of an ascent, his complete control over its movements.

The trial was in every way satisfactory, and afforded ample proof, not only of the advantage of such machines, but their adaptability to the necessities of this country. Had the load been larger, we are informed, its pace over the level road would have been even steadier than it was. On such a road as Front Street, the engine could conveniently carry twenty tons; but where hills intervene this would have to be somewhat reduced. In regard to the danger of frightening horses, anticipated by many as an objection to the use of these machines, we may say that, although a great many horses were met on the streets, only one or two standing loose at shop doors were frightened—and even these regained confidence when held until the engine passed. With the same speed as on Tuesday, the engine could pass with equal safety through our most crowded thoroughfares. The smoke appeared a smaller grievance than could possibly have been anticipated, scarcely being seen outside the smoke-stack at all. We hail the successful inauguration of this important experiment with much satisfaction, and trust it will be followed by other similar engines, to the immense advantage of the traffic of the country.

☞ Large sums of money have been expended in Texas this spring for beef cattle for the Northern markets, and extensive droves are now *en route* through Arkansas.

☞ A beet-root sugar manufacturing company has just bought four hundred and eighty-five acres of farming land in Illinois, for the purpose of raising beets.

☞ The Goderich salt company have reduced the price of salt to $1.30 per barrel. This now places it on the same basis as the Onondago salt, while it is of superior quality.

FALL SHOWS.—The exhibition of the Agricultural Societies of the South Riding of Oxford and South Norwich, will be held at Otterville on Thursday and Friday, 7th and 8th Oct., next. The Durham Fall Show will be held at Tillsonburg on the 15th October next.

WESTERN WOOL.—The Illinois Wool market has been passing through a panic, and the sheep men have been insulted almost beyond pacification by the offer of 20 to 25 cents cash for wool. One farmer took a few dozen fleeces to market, and was offered 20 cents cash or 40 cents trade at the factory. Having a pretty fair stock of strong language at command, he "delivered a short but pointed oration at the head of the factory man, and took his wool home." Enormous tariffs do not always secure high market prices for a commodity.

☞ THE fires recently kindled in the process of clearing the woods in the county of Kamouraska, have caused great ravages. Many houses have been consumed, and the fields newly sown have become the prey of the devouring element—all resulting from want of foresight, or, in other words, gross carelessness.

SALMON.—The Quebec *Gazette* says salmon are entering the bays and streams of the St. Lawrence and Bay of Chaleur districts this season in great abundance. The fish are also unusually large sized, numbers being caught of from 30 to 44 pounds weight each. These results are ascribed to the careful protection of the breeding grounds, and the restriction of netting, under the fishery laws.

TREE PLANTING.—If a farmer in Wisconsin plants a row of trees along the road, he is exempt from working on the road. Whoever hurts one of these little trees is fined $5; and the State Horticultural Society offers a premium of $100 for the best ten acres of forest trees, and $50 for the second best. Might not we in Canada take a hint from the above commendable example?

PREVENTION BETTER THAN CURE.—The Illinois Legislature has passed a law providing that any person bringing into the State seed of the Canada thistle, in the packing of goods, grain or grass seeds, or otherwise, and permitting the same to be disseminated and vegetate, shall be liable to a fine of $400; and any person allowing this thistle to mature and disseminate its seed upon his lands shall be subject to a fine of $75.

EXPORTS OF BEETROOT SUGAR FROM FRANCE.—The total exports of raw betroot sugar from France in 1867 were 27,872 tons, as compared with 26,578 tons, in 1866, and 28,279 tons in 1865. In these totals the exports to Great Britain figured for 24,223 tons, as compared with 22,076 tons in 1866, and 27,103 tons in 1865. The exports of refined beetroot sugar from France in 1867 were 87,592 tons, against 90,063 tons in 1866, and 112,230 tons in 1865. In these totals the exports to Great Britain figured for 17,994 tons, as compared with 9522 tons in 1866, and 14,142 tons in 1865.—*Grocer*

☞ THE OHIO STATE FAIR will be held at Toledo from the 21st to the 25th days of September.

PEAT.—The *Welland Tribune* learns that the company which has undertaken the work of developing the peat beds in this county have had a number of men employed for some weeks past in laying tramways from the bed to the banks of the Welland Canal. We learn that it is the intention to begin the work of excavating the fuel as soon as the pressing machines can be got on the ground, probably some time during this month.

The Apiary.

The Bee Moth

THIS insect is justly regarded as one of the worst enemies of the honey-bee, as its depredations involve the destruction of combs, brood, and stores. Happy the bee-keeper who knows how to exclude it from his hives, or arrest and prevent its devastations.

The scientific name of this pest is *Tinea mellonella*. There are said to be three kinds of it, one of which has been called *Tinea cereana;* but it seems probable that two of these are mere sexual varieties. That of medium size is regarded as the most destructive. The smaller kind is often seen at dusk in summer evenings, hovering about in front of the hives, seeking entrance. The bees evidently become excited on noticing its approach, and angrily resist it. When successful in effecting an entrance, these moths deposit their eggs in the droppings and refuse-matter on the bottom-board, if any be found there; and from it the larvæ, when hatched, derive their nourishment. The larger kind does not usually make its way into the hive till after the smaller kind have effectually secured possession and made extensive progress in the work of devastation. The color of the medium kind is grey. The egg greatly resembles that of the queen-bee. The fullgrown moth may often be seen sitting quietly on a hive, near its entrance or on some projecting ledge or corner. It frequently deposits its eggs in cracks or crevices through which the heat and odor of the hive escape.

As soon as the larvæ are hatched, they endeavor to crawl into the hive through some opening or cranny, however narrow; and if successful, at once take post in and live on the offal and particles of wax they may chance to find on the bottom. They grow very rapidly, mount the combs as soon as they can reach them, and enter the cells. Arrived there, they speedily construct their galleries, tunnelling passages along the common base of the cells, and extending their devastating course towards the centre of the comb, in quest of cells containing pollen. These appear to be their favorite resort, whence they advance revelling in the delights of havoc and destruction. Nor do these portions of comb which contain brood escape attack. The defenceless larvæ perish when the side-walls of the cells are broken down or undermined; and the ruin of the colony is sure to follow quickly, if the bee-keeper do not come to the rescue. Even though a worker occasionally lays open the gallery, the passage is too narrow to permit her to enter and dislodge the insidious foe, which, moreover, quickly retires to a safe distance.

Since only feeble stocks are overpowered by the worm, or such as, not being very populous, are at the time engaged in rearing a queen, and are consequently daily growing weaker, it occasionally happens that the bees are literally crowded out and constrained to abandon their mansion. The inexperienced and inexpert bee-keeper, seeing numbers of workers constantly massed at the entrance, fancies he has a strong and growing colony, till suddenly, on some fine afternoon, the bees come tumbling out helter-skelter, and hastily take French leave of their astonished owner. If such absconding colony was well supplied with comb, a strange spectacle of universal ruin will present itself when the hive is opened. A mixed multitude of larger and smaller cream-coloured worms with brownish heads, will be seen hastily wriggling into their hiding-place—a dark, web-strung pile of mingled excreta and crumbling comb. Hosts of fluttering moths, too, hover like harpies on dusky wing, and a nauseous odor exhales from the filmy and cocoon-spangled mass. All this is disheartening; but if the dismayed bee-keeper would have his good humor restored, and himself put in the mood of paying more heedful attention to what may thenceforward be going on in his hives, let him carry the non-moth-proof box or basket to his hen-yard, and present its contents as a *bonne bouche* or tit-bit to his Shanghais and Brahma Pootras, and he will see such an eager rush and scramble and hasty gobbling up of the multitudinous host that worked him harm, as well may mollify his temper, and restore his equanimity—so far as a hearty laugh can thereto contribute.

Then, *for prevention*.—1. Watch your hives closely, especially those that have swarmed, or that are rearing queens. 2. Frequently cleanse the bottom-boards of your feeble stocks, and inspect the combs. 3. See whether there are any black droppings under the combs, or whether the bees are carrying such out. If so, search for and remove the worm.

For *preservation of combs*—1. Insert them at times for cleaning in the hives of your stronger colonies; and 3, keep them in an air-tight box, and fumigate them every two or three weeks with fumes of burning sulphur.

In elevated mountainous districts, moths are not apt to be troublesome, but in lower level and warm districts they will, without great care, be found a numerous and intrusive pest.—*Bee Journal.*

How do Bees Track Honey?

In the second edition of "The Bee Flora of Germany and Switzerland," its author, Dr. Alefield, undertakes to show, by very plausible reasoning, that bees, when in quest of honey or pasturage, are guided not by the sense of smell, but by that of sight.

Little as might be objected to this theory so long as it regards only individual bees in search of honey, there still remains the query, how do other bees become apprised of the discovery, and by what means are they guided to the spot where the blossoming field, or the accessible honey-pot is found? In my view, Dr. Alefield should have answered this query; and as he has not done so, I submit the following solution:—

Every observant bee-keeper is aware that the returning honey-laden bee is bee-sniffed as she drops on the alighting-board, or passes through the crowd at the entrance of her hive, and is at times even very officiously overhauled and pertinaceously detained by the vigilant guards there stationed. Whether or not she gives up to them any portion of her gleanings, matters not. She is examined and diligently watched, and when she re-issues, after storing away her contributions to the common fund, the guards, now on the "*qui vive*," eagerly brush the dust from their eyes with their front feet, and keenly scrutinize the direction of her flight. Before losing sight of her, one of the guards follows in hot haste; a second pursues in the same airy path, and is rapidly succeeded by a third and fourth; and thus, in due order and succession, they arrive at the place where the first prospecting explorer accidentally discovered the coveted nectar or exposed honey-pot.

This view is sustained by the facts—

1. That the bee of one colony in an apiary will sometimes alone frequent a spot, or even rob a hive, before those of a neighbouring colony will seem to be conscious of the game or participate in the spoil. There must consequently be some mode by which the bees of the same colony are conducted to the place frequented. And the explanation I have given seems to be the most simple and natural.

2. That during the gathering season, the bees do not leave their hives in masses in the morning, but separately, one after another, in Indian file, passing on in a sort of "goose march" in the air to their journey's end; and the line of march being once established, bees of other colonies not yet conversant of the way, may join in the procession to the quarry, and become partakers of the common spoil.—*Ib.*

Bees in Cities.

SHIRLEY HIBBARD tells us that in London all the honey made by the city bees is more or less contaminated with soot. One cap of honey gathered in 1858, was so discoloured with soot that it took two months to settle, and then the bottom of the jar was coated with a black deposit, although the honey itself became comparatively clear.

Fortunately for us in America, this is a result which is very rarely met, and in almost any of our cities bees may be kept, and will produce clear and beautiful honey. We know a young artist in one of our cities, who kept a hive of bees in his studio. A window was devoted to their use, one of the lower panes of glass being about an inch and a half too short, so that an opening was left, through which projected a funnel-shaped tube made of thin wood. This tube was attached to the hive, so that the bees had perfect egress without interfering in any way with the other occupants of the room. In winter, the hive with its occupants was removed to a cool garret. The hive was very large, and we understood that in three years it had out-swarmed.—*Cor. Co. Gent.*

Horticulture.

Garden Culture of Native Wild Flowers.

Our attention was arrested the other day by a wagon-load of Moccasin plants exposed for sale in the streets. To those who were unfamiliar with these most lovely natives of our woods it must have caused no small surprise to see so much beauty and delicacy of form and colour in a wild flower; indeed, we could hardly persuade some that they were not hot-house plants. But in truth, and the lover of nature knows it well, there are numbers of our native plants that far exceed in grace and elegance their much prized sisters of the garden. In Floriculture, as alas! in everything, fashion reigns supreme; and here, as everywhere, her mandates are not always those of common sense or of good taste. Every herb and tree is in its own way beautiful, but there are degrees and varieties of beauty, and the meed of popular favor is not invariably given to the most beautiful. The changes which artificial treatment produces in flowers are besides not always improvements. The doubling, for instance, of daffodils, violets, and tulips, is, to our mind, a questionable gain in the mere mass of colour at the sacrifice of beauty and elegance of form. Perhaps our taste is peculiar, but we venture to think the garden Balsams unworthy of comparison with their rustic cousin, the yellow Touch-me-not. We confess to a very qualified admiration of Petunias, China Asters, and some other staple favorites, and are quite unable to discover the principle on which, while Hollyhocks are excluded as vulgar, the most assiduous attention of the gardener and the most honorable place in the flower show are awarded to the Dahlia. Why should a certain class of garden flowers monopolize our regard, and be considered by some as almost alone worthy the name of flower, whilst others, native to our soil and equally lovely, are passed by or perhaps looked upon merely as weeds? Is a plant less beautiful because it grows spontaneously in our woods? Must it be far-fetched and foreign before we condescend to prize or admire it? The Hepatica and the Dog-tooth Violet, so common here, are assiduously cultivated in English gardens, and some of our more beautiful native species bring high prices in the market there; as an example, we may mention that a number of Moccasin plants sent out from this country were sold in England for twelve shillings apiece, and specimens of our Pitcher-plant for as much as a guinea each. Are these unworthy of culture here? We have seen and often admired cottage gardens that owed all their attraction to a tasteful arrangement of Ferns and native wild flowers.

Comparatively few of our farmers, we are sorry to say, have any portion of their land devoted to mere ornamental purposes; many have given up even the pretence of a flower garden, whilst the attempts of others have resulted in failure. Some have no love for such foolish trifles, and some have no time to spare for this object. With the first we can hardly reason, and can only hope that their children may be better taught. To the other class we would suggest that perhaps they have attempted too much. They have begun, it may be, on too large a scale, and have been really unable to devote sufficient time for keeping so much ground in good order. But if they would curtail their ambition somewhat, they might perhaps succeed better.

Suppose, now, a plot of ground of moderate size has been set aside and prepared for a flower garden, what, it may be asked, shall be planted? We would strongly urge the farmer, who has such peculiar facilities for the innovation, to try at least the effect of substituting for those plants which he can only procure for money, or at least of adding to them, a few of our native wild flowers. There are some common cultivated flowers that have for centuries been deservedly universal favorites. First among these is the Rose. This queen of flowers affords an instance where native beauty has been enhanced by cultivation. The wild roses of our land, charming as they are, would be preferred by few to that glory of our gardens, a perfect double rose. The same advantage of cultivation must be conceded in the case of Pansies and many other triumphs of the horticulturist. But, as we have already remarked, there are not a few cultivated flowers decidedly inferior to the wild species of the same genus. The wild Columbine (*Aquilegia Canadensis*) is a much more graceful flower than the Columbine of the garden, and many other similar instances could be adduced.

It is often said that wild flowers will not grow in gardens, or at least will not thrive. They may grow, we are told, for one season, but after that they will die away. This result arises, no doubt, from inattention to the natural condition of the plants in question. If a plant is taken from the recesses of a deep swamp, and placed in the light and dry soil of a garden, exposed to the full glare of the sun, we can expect no other result than a speedy death. But where proper attention is paid to the natural habit of the plant, and pains taken to supply conditions of soil and shade and moisture similar to those by which the transplanted flower was surrounded in a state of nature, success will generally reward our care. When the Victoria Regina was first introduced into England, the hopes entertained of its flowering were repeatedly disappointed; numerous experiments were tried, until by a careful study of the habits of the plant in its natural state Sir Joseph Paxton was enabled to follow these so closely as to obtain complete success. Sir Joseph aimed carefully to reproduce the natural conditions even in such minute particulars as the slight undulation or rippling of the water which takes place in the native rivers of this magnificent and royal water lily. Such refinements as these are, of course, impossible to the ordinary horticulturist, nor are they necessary. All that is required in most cases are the conditions already specified, namely, to place the plant in a soil as nearly resembling that from which it was taken as possible, and in a similar situation as repects light and shade, and the degree of moisture usually present.

Among our native flowers suitable for cultivation may be mentioned one of the commonest, earliest, and handsomest of Canadian spring flowers, the Trillium of the woods. These will thrive well in a garden. Many species of Violet will also repay cultivation, although our native species are destitute of the delightful perfume of the English Violet (*Viola Odorata*). Some of our indigenous Orchids are especially handsome. Of these the Moccasin plant, of which we give an illustration, is perhaps the most superb, and would be justly prized in any conservatory. This species is the showy Lady's Slipper (*Cypripedium spectabile*) Less brilliant in colouring, but, if possible, even more elegant in form, is the common yellow Lady's Slipper (*C. pubescens*). These would form the most lovely additions to a garden that can be imagined, and we have known them thrive in such a situation. Our wild Phlox (*Phlox divaricata*) flourishes very well, and equals in beauty any of the cultivated varieties; and the tall Anemone. (*Anemone Pennsylvanica*) when in a rich cluster is a very effective ornament. Few plants surpass in elegance the various species of Fumatory, of which we have some choice representatives, for example that known by the name of Squirrel Coen (*Dicentra Canadensis*), or the Climbing Fumatory (*Adlumia cirrhosa*), a most elegant trailing plant of rapid growth and singularly graceful character, especially adapted for rock work. These are of easy cultivation. Many others besides these above mentioned will be readily found in any rural neighbourhood.

While we would recommend the introduction of these ornaments of our native wilds into the garden, we cannot close this article without a protest against the barbarous practice sometimes indulged in by collectors—never by the genuine naturalist—of carrying off by the roots every specimen of a rare plant to be met with in any particular locality. The man who has thus extirpated, perhaps, some beautiful and rare flower, has perpetrated a wanton act of spoliation which no ordinary scientific gain or horticultural success can excuse or cancel; and must be written down a Goth by all true lovers of nature.

Coal Oil as an Insect Extirpator.

We mentioned briefly in our last, that a correspondent had warned all gardeners against the use of oil as a remedy for insect pests, as it was death to all the plants touched by it. Since then we have received like testimony from several parties who have tried the same experiment, and one correspondent reflects rather severely upon us for giving publicity to so mischievous a recipe. We can only say that we copied the article from one of the ablest and most trustworthy horticultural publications in the world, the "*Gardener's Monthly*," and duly credited it to the source whence we obtained it, so that the recipe was given on the responsibility of another journal. Having reason to yield entire credence to the statements of our correspondents, we beg to call the attention of the "*Gardener's Monthly*" to this matter, and shall be happy to lay before our readers any explanation or item of additional information that may come to hand from that respectable source.

Timely Hints to Fruit-Growers.

As soon as a plum or cherry knot can be discerned swelling out, cut it away and burn it. When you see any sign of change in colour on the bark of your pear trees, cut away and burn that also. And when you see any black marks on the leaves of apple trees, livid spots on the grape foliage, or any other change whatever from the normal hue, cut away and burn the whole thing. By this means shall you prevent their seeding—and thus only can you ever keep in check a scourge which is really, in some neighbourhoods, a mighty obstacle to success.

So with insects; as a soldier would say, they must be attacked directly in front. Strategy is not of much use. Hand picking, tree shaking, and collecting grubs and larvæ, must be the chief reliance of the practical man. He who has not "time" to attend to these things, will have to buy his fruit of those who have. It seems hard-hearted to pronounce such a doom, but we feel it to be a truth; and the sooner all realize it the better, if it must be.—*Gardener's Monthly.*

☞ A correspondent of the *Iowa Homestead* says that when he wants to prepare labels for his trees and plants he makes them of cedar, then takes a Faber No. 1 pencil, rubs a little linseed oil on the place where he intends to write, and writes before it gets dry. By this means the name will remain indelible for many years.

Summer Meeting of the Ontario Fruit Growers' Association.

The Ontario Fruit Growers' Association held their summer meeting in the Agricultural Hall, in this city on last Wednesday. There was a very large attendance of members and others interested in the objects of the Society. The chair was occupied by the President, W. H. Mills, Esq., of Hamilton. Among those present there were besides the Secretary, D. W. Beadle, Esq., of St. Catharines; Hon. W. Allan, Messrs. Geo. Leslie, senr. and jr., John Gray, John Fleming, James Gibson, H. Brown, and W. Vair, of Toronto; Rev. R. Burnet, W. Holton and L. Springer, of Hamilton; N. Hamilton and C. Arnold, of Paris; Dr. Cross and W. Eccles, of St. Catharines; F. Chisholm, of Milton; W. Reid, of Port Dalhousie; D. Caldwell, of Galt; W. W. Cook, of Cooksville; P. T. Springer and S. M. Durkee, of Wellington Square; S. Lewis, Winona; L. Bishop, St. Thomas; A. M. Smith and D. Van Duser, of Grimsby.

Some very splendid specimens of fruit were exhibited, among which, as might be expected from the season of the year, strawberries predominated. Mr. George Leslie sent some really magnificent samples, of the following varieties:—Agriculturist, Jucunda, Trollope's Victoria, Russell's Prolific, La Constante, and Dr. Nicaisse, the latter a new variety, now first fruited in Canada. Mr. J. Gray sent specimens of Triomphe de Gand and Wilson's Albany. Mr. H. Brown, of this city, exhibited a dish of remarkably fine Trollope's Victoria, the size and quality of which were much admired. A new seedling strawberry, called Bishop's Canada Seedling, was shown by Mr. Luke Bishop, of St. Thomas. There were also on the table a few plates of cherries, Mr. Gray exhibiting the variety known as Governor Wood, and Mr. Leslie the Brockpert Biggarean. A plate of early ripe apples, nectarines, apricots and peaches, grown in an orchard house, were exhibited by C. S. Gzowski, Esq. There were very fine specimens of the fruit, fully ripe and of excellent flavour. A few hybrid seedling raspberries, very early, for they were already ripe, were shown by Mr. C. Arnold. Nearly all these specimens formed subjects of discussion in the subsequent proceedings.

The business of the meeting commenced by the Secretary reading the minutes of the last meeting held at Hamilton, which were confirmed. The Directors then submitted to the Association the following report of the Committee appointed to examine Mr. Luke Bishop's seedling strawberries.

To the Board of Directors of the Fruit Growers' Association of Ontario.

The Committee appointed to repair to St. Thomas and there personally inspect the new seedling strawberry growing upon the grounds of Mr. Luke Bishop of that place,

Would Respectfully Report:

That they have examined the seedling strawberry raised by Mr. Luke Bishop, of St. Thomas, at his grounds:

That they find the plant to be a strong and vigorous grower, coarser in foliage and more rank than the Triomphe de Gand; in habit reminding one of Russell's Prolific:

That the flowers are hermaphrodite, but only six or seven berries are formed upon each foot-stalk, and these very evenly developed in size:

That the berries may be justly said to be of large size, but not monstrous; in color they are bright red, and make a very handsome appearance. The flavor is particularly agreeable, not too acid like the Wilson, but more decided than the Triompho de Gand, an unusual mingling of the Pine and Hauthois flavors without the excessive distinctness of the latter; while the fragrance is more than usually abundant, filling the room from a plateful of fruit. The berry is not as firm as the Triomphe de Gand, and will not bear transportation over long distances as well as that variety:

That in productiveness it is not equal to the Wilson, though the fruit is more uniform in size, while the crop seemed to be fully equal to the Triomph de Gand under most favourable culture. The plants set last August showed a very good amount and size of fruit, particularly those from which the runners were kept off; plants allowed to run together so as to form a thick bed were deficient in fruit. No doubt this variety will succeed best cultivated in hills.

That the Committee can not speak of the hardihood of the plant further than to say that the plants upon Mr. Bishop's Grounds were very healthy, and that the better to test the qualities of this seedling, Mr. Bishop has already placed some of the plants in the hands of the Directors, with Mr. Arnold at Paris, President Mills, at Hamilton, and the Secretary at St. Catherines.

That we commend this new seedling strawberry to the attention of amateurs on account of its fine flavor, delightful perfume, handsome appearance and general uniformity of size.

Your Committee take the liberty of suggesting to the Directors the propriety of establishing a rule that before appointing a Committee to examine seedling fruit on the grounds of the producer, such fruit shall have been exhibited at least once at some meeting of the association; also to state that they were deeply impressed with the importance of diffusing popular entomological information by witnessing the entire defoliation of nearly every orchard between London and St. Thomas, and to suggest the propriety of appointing a suitable person Entomologist to the Association, to whom can be referred all matters relating to insects injurious to fruit culture as they may arise, and who will be able to investigate their habits and report thereon.

All of which is respectfully submitted.

WM. H. MILLS.
D. W. BEADLE.
WM. SAUNDERS.

July 1st, 1868.

A committee was next appointed, consisting of Hon. W. Allan, C. Arnold, W. Holton, and Geo. Leslie, sen., to prepare a programme of subjects for discussion. These gentlemen having retired for consultation, shortly returned with their recommendations, embracing the following topics:—

1st. The merits of the different varieties of strawberries at present on the table.

2nd. The merits of any new varieties of strawberries, and whether any of them can be specially recommended, either as an earlier sort than those at present in general cultivation, or as coming in later and supplying the market between the general strawberry crop and the ripening of the raspberry crop.

3rd. The best six varieties of cherries for general cultivation, and if any and what varieties succeed best as dwarfs.

4th. The best four hardy varieties of raspberries for general cultivation.

5th. On insects injurious to plants, and the best modo of exterminating them.

The first of the foregoing subjects was at once taken up.

Mr. G. Leslie, senr., spoke very favourably of the Agriculturist, having found them, especially on a clay soil, very productive, even more so than Wilson's. He considered the variety worthy of more extensive cultivation. The Jucunda, also grown by him on stiff clay soil, had proved a fine berry, though less productive than the preceding; in flavour not quite equal to the Triomphe de Gand, but of good quality for carriage. Russell's Prolific he considered should be struck off the list, as it does not set its fruit well, and is in many respects inferior to other varieties. Trollope's Victoria yielded a very large fine fruit, well suited for the table, but was a poor bearer and rather tender, and altogether fit only for amateur cultivation. La Constante had the advantage of being a late bearer, the specimens shewn being the first gathered and not yet quite ripe, but he had found it a poor bearer, and could not recommend it for cultivation. The few specimens of the new variety, Dr. Nicaisse, he could not say much about, as this was the first occasion of their being fruited in Canada.

Mr. C. Arnold had not a very high opinion either of the Agriculturist or the Jucunda; indeed he had not found any variety equal to the Wilson.

Mr. N. Hamilton, of Paris, had found the Triomphe de Gand, taken all together, the best variety for his own use, though the Wilson was perhaps a better market berry.

Hon. G. W. Allan had formed a very favourable opinion of Trollope's Victoria, and considered it a very suitable variety for the amateur. In rich clay loam he had found it bear well and the fruit was of fine size and delicious flavor.

A number of the members present expressed their opinions on the varieties under discussion. The Wilson's Albany was admitted by all to be the best market berry, though some objected to its acidity, which was, however allowed to be in some measure due to its being often gathered before it was fully ripe. The Agriculturist was highly spoken of, Mr. Read, of Dalhousie, remarking that it had one proclivity and

excellence in its habit of stooling rather than making runners. He had also found it best adapted for clay soil. In this opinion Mr. Smith and others fully agreed. Next to the Agriculturist and the Triomphe de Gand the Jucunda received the commendation of those who had grown it. Mr. Gray confines his cultivation to two varieties, Wilsons and Triomphe de Gand. The latter he considered the finest flavoured strawberry we have, the former he had found an enormous bearer. He cultivated in hills, carefully taking off the runners. Dr. Cross, of St. Catharines, after having tried most of the varieties under discussion, now only grew Wilson's, Hovey's, and Triomphe de Gand.

After a short recess the second subject was taken up for discussion, and in connection with this topic Mr. Bishop gave some account of his now seedling strawberry, a cross between Triomphe de Gand and Wilson's Albany. He had now had it three years. It was, he said, rather earlier than Wilson's and will last longer; he considered it also as hardy a variety as any that we have in cultivation. In crossing to procure the hybrid, he had fertilized sometimes with the Triomphe de Gand, and sometimes with the Wilson.

Mr. Beadle said that he considered the flavor of Mr. Bishop's seedling to be its chief excellence, in which respect it was superior to most of the varieties generally cultivated.

Mr. Mills fully endorsed what was said by Mr. Beadle, and spoke in addition of its peculiar and delightful fragrance.

The specimens on the table were exhibited under the disadvantage of having been gathered on the day previous and being over ripe. Notwithstanding this drawback, the flavor was to our taste very agreeable, and we were favourably impressed with the general excellence of the seedling, and considered it deserving of a careful trial.

The following resolution, moved by Mr. C. Arnold, seconded by Mr. Gray, was carried unanimously—

"That the thanks of this Society be given to Mr. Bishop for his efforts in producing a new seedling strawberry, and that it be recommended for further trial."

At this stage of the proceedings the following resolution was moved by Mr. Leslie, Junr., seconded by Mr. Gray, and carried—That the recommendation of the Fruit Committee contained in their report on Mr. Bishop's Seedling Strawberry, viz: "that before appointing a committee to examine seedling fruit on the grounds of the producer, such fruit should have been exhibited at least once at some meeting of the Association," be adopted as a rule of this Society.

The next subject in order, namely, the best six varieties of Cherry, was then taken up, and after some discussion, a vote on the question was taken, resulting in the recommendation of the following in the order named, the first three receiving each an equal number of votes: Governor Wood, Black Eagle, Elton, Black Tartarian, and Black Heart.

Mr. Gray spoke well of the wild cherry of the country as a stock for grafting the cherry upon; not the bird cherry or choke cherry, but one bearing clusters of red berries in the same manner as the cultivated kind.

The fourth topic for discussion was then introduced by Mr. Arnold, who exhibited some white raspberries, ripe at this early season. They were a hybrid between the White Marvel of four seasons and the White Cap. Mr. Beadle thought the Franconia, Philadelphia, Arnold's red, and Arnold's white hybrids to be the most hardy. Mr. Chisholm found the Black Cap to be the hardiest. Mr. Eccles considered the Fastolff the most excellent in this respect. Mr. Gray preferred the Brinckle's Orange and the red Antwerp. Mr. Read grows successfully Brinckle's Orange, Fastolff, Franconia, and Doolittle's Black Cap. Mr. Arnold finds Franconia and Belle de Fontenay the hardiest European sorts, but none of them can be depended upon, while the Philadelphia is perfectly hardy, and is among raspberries what Wilson's is among strawberries. Mr. Caldwell, of Galt, finds the Franconia and Philadelphia the hardiest. Dr. Cross prefers the red and white Antwerp and Franconia.

The fifth and last subject came up too late in the day for any prolonged or adequate discussion. Mr. Beadle stated in answer to enquiry that the caterpillar which had proved so destructive to the orchards between London and St. Thomas, was a species of tent caterpillar, not the common variety, *Clisiocampa Americana*, known by its large webs or tents, but a closely allied species, *Clisiocampa Sylvatica*, which does not make so large a web, and is therefore in its early stages not so easily detected. In the district alluded to they occurred in countless myriads, and had been mistaken by some for the army worm, probably because "their name was legion." A few remarks were made in reference to that ubiquitous pest the Curculio, the majority of the members present concurring in the opinion that jarring the trees, collecting the beetles, as they fell and destroying them, was the only effectual remedy. Mr. Arnold, however, stated that he had failed to make any impression on them by this method, and had found liming or whitewashing the ground about the trees more efficacious.

Mr. Beadle presented a report on the the Fruit Prospects of the Niagara District, but said that he would not detain the meeting by reading it then, but would leave it with the Editor of THE CANADA FARMER for publication in that journal. We append the document to this report. The observations on the strawberry may be deemed now beyond their season, but are valuable as a record of experience.

After a very interesting session the meeting adjourned.

During the latter part of the proceedings, the chair was occupied by Mr. Leslie, senior, Mr. Mills having been obliged to return to Hamilton early in the afternoon. The thanks of the meeting were voted to the chairman.

THE FRUIT PROSPECTS IN THE NIAGARA DISTRICT.

To the Fruit Growers' Association of Ontario.

When the spring opened, and the fruit trees put forth their buds and blossoms, there seemed to be a promise of an abundant crop of fruit, and expectations were entertained of a more than usually large supply. But as the season advances we find that many of our fruit trees are but very sparsely set with fruit, and that from one cause and another the quantity of fruit is likely to fall far short of our previous expectations.

At the time that our apple and pear trees were opening their blossoms we were visited with a season of protracted rains, the prevalent wind was from the north-east, and was very bleak and chill. Owing to this circumstance, the pollen of the flowers was but imperfectly developed and was washed to the ground. Had the air been usually dry and warm, the delicate grains of the pollen would have been carried by the currents of air, and by the busy insects, to the stigmas of the flowers, resulting in an abundant fertilization; but on the contrary, during the period of fructification the pollen was kept wet and paste-like, so that it could neither float in the air nor adhere to the hairy legs of the bees and other insects, and so failed of reaching its nature-intended destination. Hence but a small proportion of the fruit is set, and our apple trees and pear trees, so loaded with flowers, will yield but little fruit.

To this cause may also be attributed the curled leaves on the peach. Any one who has grown the peach under glass knows how sensitive the foliage is, when it is just putting forth, to any chilling draught or current of air, and has seen the leaves curl and at length drop off from this cause, just as they have curled and dropped off in the open air this spring. It may be that of late years we have been much more subject to the chilling easterly winds in the spring, that from the clearing up of the forest those winds have a longer sweep and greater power, and that our peach trees, from continued exposure to debilitating influences, are become less vigorous and more sensitive to atmospheric changes. Be this as it may, the upleasant fact remains that for a number of years our peach trees have more or less been afflicted with this curl of the leaf in spring, resulting in the loss of the first foliage and a dropping off of the fruit.

As the season has advanced the pear trees have again been afflicted with the blight, large branches have turned black in the bark, the leaves have withered and turned black, the fruit on these branches shrivelled and dried up, and the trees look as though they had been scorched with fire. It is not necessary to offer any speculations upon the nature and cause of this disease; as yet it is shrouded in mystery, and he who shall be able to discover a preventive or a cure for this destructive disease will confer a boon of no ordinary value upon the cultivators and consumers of the pear.

The strawberry crop has not been as large as usual this season. The deficiency is probably owing to the long-continued drought of last summer. Plantations that were carefully covered during the winter fell short full as much as those that were left unprotected, and of all the varieties usually grown in this Township, the French's Early and the Wilson seemed to show the greatest deficiency, as compared with their usual yield, while the Triomphe de Gand came more nearly up to its usual standard.

Of the newer varieties not one has been able, under the treatment given, to equal the Wilson for general cultivation and productiveness. The "Agriculturist," with special care and high feeding, will yield some monstrous berries, but beyond that has nothing to commend it, and in that respect must yield to the "Dr. Nicaise," whose monstrous fruit astonishes the natives. The celebrated "Tribune Strawberries" have failed to exhibit any special excellencies, and will soon be dropped from cultivation. The "Jucunda" has so far done the best of the newer sorts; its berries are large, more nearly uniform in size than the Wilson, of a better colour, and the crop is larger than that of the Triomphe de Gand. The "La Constante" has not yet been sufficiently grown here to judge of its merits. The "Russell's Prolific" fails to fertilize itself, requiring Longworth's Prolific, or some other variety abounding in pollen and flowering at the same time, to be planted near it, in order to perfect its fruit. The writer is disposed to believe that the "Russell's Prolific" and the "Jucunda" flourish best in a strong clay loam. The strawberry cultivator is not likely to lack new varieties with which to experiment for some time to come. Not less than fifty new seedling berries were exhibited at the last meeting of the Western New York Fruit Growers' Society, held on the 24th June, each one supposed to possess some new excellence and special claim upon the attention of the public. There is, however, yet wanted a strawberry of vigorous habit and hardy constitution, as productive as the Wilson, berries large and more nearly uniform in size, bright colour, high flavor, sufficiently firm to bear transportation well, and ripening after the Wilson is gone.

Our cherry crop was thinned from the same cause which lessened the apples and pears, but the Heart and Bigarreau Cherries have thus far suffered less from rot than they did last year, so that we have more fruit than we realized last season. The "Reine Hortense" and "Belle Magnifique" and "Late Duke" varieties are yielding little or no fruit, but the "Mayduke" has an abundant crop.

The currant worm and gooseberry saw-fly are much less numerous this season, whether owing to the use of White Hellebore, or to one of those unaccountable disappearances which every student of entomology has noticed, it may not be easy to determine. The fact is none the less gratifying, and our gooseberry and currant trees are yielding a good supply of fruit. Even those who continue to cultivate the English varieties (with a perseverance worthy of better success) are hoping to escape the fatal mildew this season, at least in a good degree.

Of the raspberries, several varieties passed through the winter either wholly uninjured or but slightly hurt, while even the tenderer sorts will yield some fruit. The "Hornet" and "Pilate" suffered but little, "Brinckle's Orange" and "Franconia" still less, and the "Philadelphia" and "Arnold's White" and "Arnold's Red" not injured at all. The "Naomi," judging from two years' trial, is but little more hardy than Francoula. "Souchetti" is as tender as the old White Antwerp. There is every promise of an abundant yield of Raspberries, and if we are succeeding in obtaining a class of raspberries that will endure our winters without protection, with juicy, high flavored, and large sized fruit, a new impetus will be given to raspberry culture. Of the "Clarke" and "Davison's Thornless" varieties it is too soon to speak.

Blackberry culture is as yet very limited in this vicinity. The "New Rochelle" is large and very productive, but the plants sometimes are a good deal killed back in winter, and the fruit, unless left on the vines until ready to drop off, quite too acid. Experiments are being made with the "Wilson's Early" and the "Kittatiny," in hopes of finding something more desirable.

Those who have been faithful in carrying on the war with the curculio, or plum weevil, are reaping the reward of their labour in a fine crop of smooth, uninjured plums; several have found that a little well directed labour in jarring down the insects, and destroying all fruit stung by them, secures a fine crop of plums at but little cost.

The grape vines have bloomed freely, and are setting their fruit well, so that there is every prospect that when the Association holds its October meeting in St. Catharines, the Niagara District will be able to exhibit an abundance of grapes.

From this hurried survey of the fruit crop in this vicinity, we can see that the Fruit Grower has his difficulties to meet, but that on the whole he has much to cheer and stimulate him to careful experiment and untiring zeal.

D. W. BEADLE.

Grantham, July 7th, 1868.

Hamilton Horticultural Show.

To the Editor of THE CANADA FARMER:

SIR,—As it may be interesting to many of your readers to note the progress that horticulture is making in Canada, I send a brief report of the recent Hamilton Fruit Show. The Directors of the Hamilton Horticultural Society held their second show of the season in the large and commodious Drill Shed on the first of July (Dominion Day.) The entries were over 800, embracing many fine varieties of flowers, fruits, and vegetables, amongst which I noticed a very fine collection of orchard house trees, figs and peaches, loaded with fruit; also some grape vines, grown in pots, and very well fruited. Next in order were very fine collections of greenhouse and stove plants, many of them in full bloom. The growers certainly deserve great credit for the skill and care bestowed in producing such fine specimens.

In Fruit, the strawberries being in the greatest perfection at this season, many fine dishes were shown. Wilson's Albany and Triomphe de Gand seemed to take the lead. There were also some very fine samples of the Jucunda and the Agriculturist, with some other varieties not so well known. Of cherries I noticed two fine dishes of black hearts, but the general crops not being ripe, the show in this department was limited. In apples a few specimens of well-kept Roxburg Russets were on the table. In the Vegetable assortment the show was extensive and fine, embracing collections of cucumbers, tomatoes (ripe), cauliflower, very fair onions, carrots, cabbages, lettuce, radishes, and many other varieties in great perfection. I would notice particularly the collection of potatoes. The kidneys were very fine. In sound potatoes the early Goderich will no doubt take the lead.

In concluding these brief remarks, I would just say a word to other Horticultural Societies—Our Great Exhibition takes place at Hamilton this fall, and it behoves all the Horticultural Societies of the province to stir up their members to send up their very best productions on the occasion, so that Canada, and the Province of Ontario, may show to the world what we can produce.

HORTENSIS.

Western New York Horticultural Society

THE Annual Summer meeting of the above Society was held in Rochester, June 24th. Strawberries were shown in great variety, and a parcel of Coryelle grapes preserved from last autumn's vintage, and retaining their freshness to such a degree that they bid fair to show well for some weeks yet. Reports in reference to fruit prospects were not flattering; apples and pears especially are likely to be a light crop. The following questions were reported for discussion by the business committee, and most of them were taken up by the meeting.

"*First*—What are the best varieties of fruit for canning, and what is the best manner of doing it?

"*Second*—What is the best size of can for keeping fruit, and the best material to make cans from?

"*Third*—Is there any method of preventing the ravages of the army worm in apple trees?

"*Fourth*—What is the best remedy for the steel-colored grape beetle and grape worm?

"*Fifth*—Is there any remedy for the insect that preys upon Arbor Vitæ?

"*Sixth*—What new varieties of strawberries promise well?

"*Seventh*—What are the three best varieties of currants?"

The peach, pear and quince appeared to be the favourite fruits for canning. Glass cans were preferred for domestic use, tin ones for transportation, and the gallon size found most favour. Much discussion was had on the insect queries, without eliciting anything of special interest. Copperas water was recommended by one member as an effectual remedy for the grape pests: four ounces of copperas dissolved in a quart of hot water, and then another gallon added. Jucunda and New Prolific were mentioned as promising new strawberries. The currant question was not discussed.

Caterpillars on Gooseberry Bushes.

WE give the following method of destroying caterpillars, on the authority of the *Farmer* (Scottish):—

"This season, as usual, the appearance of caterpillars on gooseberry bushes has caused considerable anxiety in several parts of the country. In many districts in Fifeshire, and particularly at Newburgh, a famed and very extensive fruit-growing strath, this pest is doing much mischief. As in the case of other plagues, sundry remedies are being suggested and applied for the purpose of getting rid of the vexatious visitation, some of which savour not a little of the superstitious. For instance, one party has had twigs of broom stuck in amongst the branches of the bushes; and another has planted rue (*Ruta graveolens*) and chamomile (*Matricaria chamomilla*) plants at their roots, for the purpose of getting rid of the pests. These, nevertheless, may tend in some way in making the caterpillars less voracious on the bushes so treated, for the smell as well as the bitter tastes of such are, doubtless, disliked by insects. Hellebore powder, lime and soot have also been applied, but nothing so effectually destroys the vermin as soot, which is, independently, the cheapest cure and the most certain preventive. When dusted on the bushes after a slight shower has fallen, or after the leaves have been wetted, the vermin will soon drop off the leaves and perish. The application of a sprinkling of dry soot round the roots of bushes, when early digging operations are being proceeded with in spring, will act most successfully in preventing their appearance, and this resorted to in successive seasons will entirely extirpate the pests. In doing so, however, it is necessary at every application to remove the soil slightly round the roots of the bushes, and supply fresh soil in place of that removed. This has been tried with best results for many years.

The Household.

How to make Spruce Beer.

As the season is here when pleasant summer drinks, free from alcoholic influence, are frequently brewed by the housewife, or the well brought up daughters—who ought to be taught a little of everything in the way of household duties—we append the following recipes, which are claimed to be excellent:

1. Take three gallons of water of blood warmth, three half pints of molasses, a table-spoonful of essence of spruce, and the like quantity of ginger; mix well together with a gill of yeast; let it stand over night, and bottle in the morning. It will be in a good condition to drink in twenty-four hours. It is a palatable, wholesome beverage.

2. Those who prefer *mead* have only to substitute honey for the molasses named above, and for one-third the ginger use allspice. Half the quantity of yeast will be sufficient, and the bottling should occur the second day instead of the next morning. It will be fit to drink in four days after being bottled, and will keep for many weeks. A small quantity of alcohol is formed during the fermentation, and this prevents the acetous fermentation so common to spruce beer. The essence of spruce is of course left out in the making of mead. The alcohol formed from the fermentation of honey resembles that found in *metheglin*, while the alcohol formed from the fermentation of molasses is *rum*. Those who imagine that they can make their spruce beer or mead without entirely forming any alcohol are mistaken; but it is present in so slight a proportion as not to be sensible to the most delicate temperance nerves.—*Selected.*

To Cure Meat.

To 1 gallon of water take 1¼ lbs. of salt, ¼ lb. of sugar, ½ oz. of saltpetre, ½ oz. of potash. In this ratio the pickle to be increased to any quantity desired. Let these be boiled together until the dirt from the sugar rises to the top and is skimmed off. Then throw it into a tub to cool, and when cool pour it over your beef or pork, to remain the usual time, say four or five weeks. The meat must be well covered with pickle, and should not be put down for at least two or three days after killing, during which time it should be slightly sprinkled with powdered saltpetre, which removes all the surface blood, etc., leaving the meat fresh and clean. Some omit boiling the pickle, and find it to do well, though the operation of boiling purifies the pickle by throwing off the dirt always to be found in salt and sugar. If this receipt is properly tried it will never be abandoned. There is none that surpasses it, if so good.—*Journal of Agriculture,*

A WITTY REPLY.—"Did you ever see a lunar bow, miss?" said an astronomer to a bright-eyed girl, when talking of rainbows. "I have seen beaux by moonlight, if that's what you mean," was the sly rejoinder.

☞ Sydney Smith wrote to a friend, "Unfortunately the house is full of cousins; would they were once removed!"

DOING IT MILD!—The funniest incident that has lately transpired is the case of a doting mother, who, being satisfied that her child merited a flogging, insisted on his previously being put under the influence of chloroform.—*American Paper.*

AS OUR MOTHERS DO.—We were considerably amused the other evening at three little girls playing among the sage brush in a back yard. Two of them were "making believe keep house" a few yards distant from each other—neighbours as it were. One of them says to the third little girl: "There, now, Nelly, you go to Sarah's house, and stop a little while and talk, and then you come back and tell me what she says about me, and then I'll talk about her; then you go and tell her all I say, and then we'll get mad and won't speak to each other, just as our mothers do, you know. Oh, that'll be such fun."—*American Paper.*

HOSPITALITY.—There are some people who would like to make their friends welcome, but spoil their pleasure by over-exertion. The guests are made to feel uneasy by the visible effort put forth to entertain them. The whole secret of putting our friends at ease, is to be at ease ourselves. And in order to be thus, we must not misinterpret their visit. They have not come to see our furniture, our equipage, our dress, but ourselves. Courtesy, then, rather demands our society and conversation than our silver ware and cookery.—*Anon.*

First Prize Cheese Vats!

TO THE DAIRYMEN OF CANADA.

THE UNDERSIGNED keeps constantly on hand the following articles: Cheese Vats and Heaters of all sizes and styles. Red Cherry Press Hoops and Followers, (turned). Screws of all sizes and patterns. Carrying Cans and Dairy Pails, of the best material. Bleached cotton Bandage Cloth, imported expressly for the trade; and everything required in the manufacture of Cheese

AT LOWEST REMUNERATIVE PRICES.

☞ My Vats took First Prize and Diploma at last Provincial Exhibition.

Address H. PEDLAR,
Box 100 Oshawa, Ontario.

v5-10-tf

MILLER'S

INFALLIBLE

TICK DESTROYER FOR SHEEP!

DESTROYS the TICKS; cleanses the skin; strengthens and promotes the growth of the wool, and improves the condition of the animal.

It is put up in boxes at 35c., 70c., and $1, with full directions on each package. A 35c. box will clean twenty sheep.

HUGH MILLER & Co.,
167 King Street East. Medical Hall, Toronto.

v4-14-tf

TO FLAX GROWERS.

THE undersigned will have, the present season, a supply of FLAX-PULLING MACHINES, which we can guarantee to do good work, having been fully tested last season. New improvements added this year. Send for cut of Machine and Price List.

OSWOLD & PATERSON,
Woodstock Iron Works.

1st May, 1868. v5-9-6t.

SMALL CHEESE VATS!

H. PEDLAR, Manufacturer, will send to any Railway Station in the Province of Ontario, (free of charge,) a first-class Cheese Vat, all complete, to running order, suitable for twenty to thirty Cows, on receipt of $30.

☞ All work warranted to give satisfaction.

Address H. PEDLAR,
Box 100, Oshawa, Ont.

v5-10-tf

Duncan's Improved Hay Elevator.

PATENTED April 13th, 1867.

THE cheapest and simplest constructed Fork in use in the Dominion of Canada. County or Township Rights for the manufacture of the above Fork may be obtained from the undersigned.

Paxton, Tate & Co., Port Perry, Ont.,

MANUFACTURERS OF THE

MARSH HARVESTER!

AGRICULTURAL IMPLEMENTS

OF ALL KINDS,

STAVE & SHINGLE MACHINERY,
OSCILLATING MULLEY SAWS,
TURBINE WATER WHEELS,
MILL CASTINGS, etc., etc.,

MADE TO ORDER.

☞ *Repairing of all kinds promptly attended to.* ☜

WARRANTY.

We warrant the Marsh Harvester to be well made, of good material, and when properly used, not liable to get out of repair; to be a good grain-cutting machine upon which two experienced binders can bind in average grain, on suitable ground, from eight to twelve acres in twelve hours; and that it will work on as rough ground as any other Reaper

PAXTON, TATE & CO.

Port Perry, March 28, 1868. v5-7-tf

Farm of Prospect Hill

TO LET, for a Lease of 10 or 12 years, from and after 1st October next:

Being Lot 16, Con. 12, East Zorra, Oxford, 200 acres, occupied by the heirs of the late W. Dawson, Esq.

This is a first-class farm either for cropping or dairy purposes, and is in a high state of cultivation; 160 acres arable; well watered and fenced. Excellent Dwelling House, large Orchard, and extensive Farm Buildings, suitable for dairy purposes. By gravel road, 6 miles from Woodstock; 1 mile from Strathallen cheese factory.

Should an intending tenant take the stock and crop, by valuation, he could have immediate possession. Apply on the premises, or by letter post paid, to

MRS. DAWSON,
SOUTH ZORRA, ONTARIO.

Prospect Hill, 26th June, 1868. v5-14-2t.

J. H. THOMAS'

FIRST PRIZE BEE HIVES!

Persons desirous of purchasing territorial rights for my Hives, would do well to apply at once, as I will sell for the next two months, Townships at from $20 to $30, and Counties from $50 to $150.

J. H. THOMAS,
Brooklin, Ontario.

N.B.—Parties residing in the Counties of Carleton, Russell, Ottawa, Pontiac, Renfrew, Lanark, Leeds, Dundas, Stormont, Glengarry and Prescott, and desiring to purchase my Hives, must in all cases address their orders to JOHN HENDERSON,
v5-8-tf New Edinburgh, Ont.

ITALIAN QUEENS.

HAVING made arrangements for BREEDING a large number of Italian Queens, I will be able to fill all orders for the same, guaranteeing their purity and safe arrival by express. Have obtained two very fine Queens through Mr. Gray, of Ohio, for breeding purposes, and therefore prepared to furnish Queens of a bright color, and producing fine workers. **Price $5 Each.**

Bee keepers would do well to send their orders at once.

J. H. THOMAS.

GEO. A. DEITZ,

The Great Seed Wheat Grower,

CHAMBERSBURG, Pa., sends free a Descriptive List of the best Seed Wheats in the world. v5-11-6t

Markets.

Toronto Markets.

"CANADA FARMER" Office, July 13th, 1868.

FLOUR AND GRAIN.

The produce market continues quiet. There is rather more firmness in the market, and an advance on flour has been established.

Flour—The market is firm, with an advancing tendency. The demand has improved, and stocks being light, prices have advanced. To-day 100 bbls No. 1 super. sold at $6.40, and 300 barrels do. sold at $6 56. Holders generally are now asking $6 50 for No. 1 super. A 100 barrel lot of spring wheat, extra, sold at equal to $6 60 here.

Wheat—There is more firmness in the market, and holders have finally advanced their prices. For spring wheat $1 45 is now generally asked. We heard, however, of no sales at that figure. Fall wheat is offering at from $1 48 to $1 53 according to quality. $1 53 was offered to-day for a lot of choice fall, and refused. We heard of no sales of wheat to-day.

Oats—The market has advanced. For retail lots 55c. is now asked.

Barley.—Nothing doing.

Peas.—The market is firm. We heard of no sales to-day. Worth nominally from 85c. to 88c.

Eggs—Scarce, and in good demand. Selling at from 14c. to 16c.

Butter—Dairy tub per lb. 13c. to 14c.; store packed 11c. to 12c.

Cheese—10c. to 11c.

Pork—Mess, per bbl. $22 to $23; prime mess, $17 to $18; extra prime, $15 50 to $16 50.

Bacon—Cumberland cut, 10½c. to 11c.; roll, 12½c. to 13½c.

Hams—12½c.; covered, 13c. to 13½c.

Shoulders—Smoked, 10c. to 10½c.

Lard—In kegs, 13½c. to 14c.

Eggs—Packed, 16c. to 17c.

Beef Hams—13c.

Tallow—7c. to 8c.

Hides and Skins.—Hides, green, rough, per lb. 5½c. to 6c.; green inspected, 7c.; cured and inspected, 7½c to 8½c. Calfskins, green, 10c.; cured, 12c.; dry, 18c. to 20c.

Wool—Per lb. 26c. to 27c.

Hops—Inferior, per lb. 10c. to 15c.; medium per lb. 15c. to 20c.; good per lb. 20c. to 30c.

CATTLE MARKET—There has been a complete stagnation in the cattle market during the past week, the hot weather and strawberry season having lessened the demand for meat. The prices are considerably lower, having declined 1½c. per lb. since our last report. We quote per 100lbs. dressed weight:—1st class cattle, $6; 2nd do. $5; 3rd do. $4. *Sheep* have been in plentiful supply, but have not been in good demand. It was difficult to effect sales. We quote:—1st class $4; 2nd do. $3; 3rd do. $2 50. *Lambs* have been scarce and in demand. We quote: 1st class $2 50 each; 2nd do $2; 3rd do $1 50. *Calves* have been more plentiful and are lower. We quote: 1st class $6 each; 2nd do $4; 3rd do $3.

Montreal Markets, July 13.—*Flour*, superior extra, $7 50; extra, $7; fancy, $6 90; Welland Canal superfine, $6 60 to $6 70, superfine No. 1, Canada wheat, $6 60 to $7; superfine No. 1, Western wheat, $6 25 to $6 60; No. 2 do, $6 20 to $6 30; bag flour, $3 40 to $3 50. *Wheat*—Canada Fall, $1 60; Canada Spring, $1 55 to $1 56; Western, $1 50 to $1 52]. *Oats*—Per 32 lbs. 42c to 43c. *Barley*—Per 48 lbs. 90c to 95c. *Butter*—Dairy, 15c to 17c; store packed, 13c to 16½c. *Cheese*—9c to 10c. *Ashes*—Pots, $5 65; pearls, $5 45. *Pork*—Mess, $24; Prime Mess, $16 25; Prime, $15 25. *Peas*—$1 5 to $1 10. *Rye Flour*—$5 75 to $6.

Milwaukee Markets.—July 11, noon.—Wm. Young & Co.'s report.—Wheat—Receipts, 5,000 bushels; shipments 37,000 bus. No. 1 wheat quiet at $1 86; No. 2 do. at $1 78. Flour unchanged. Pork firm at $26 25. Freight nominal.

Chicago Markets, July 11, noon.—William Young & Co.'s report.—*Wheat*—Receipts, 3,000 bushels; shipments, 18,000 bushels. No. 2 wheat inactive at $1 80. Corn easy at 93c; receipts 181,000 bush.; shipments, 337,000 bush. Pork firm at $28 50.

New York Produce Market.—July 11.—*Flour*—Dull and drooping; receipts 3,700 bbls; sales 7,800 brls at $5 75 to $7 20 for super. state and Western; $8 00 to $8 70 for common to choice extra State; $8 75 to $10 for common to choice extra Western.—*Rye Flour*—Steady at $7 75 to $9 80. *Wheat*—Dull; receipts, 85,000 bush. *Rye*—Quiet; sales 4,000 bush. Western at $1 86; Canada at $1 87.

THE CANADA FARMER is printed and published on the 1st and 15th of every month, by the GLOBE PRINTING COMPANY, at their Printing House, 26 and 28 King Street East, Toronto, Ontario, where all communications for the paper must be addressed.

☞ Subscription Price $1 per annum, (POSTAGE FREE,) payable in advance. Bound volumes for 1864, 1865, 1866 and 1867, may be had for **$1 30** each. Subscribers may either begin with No. 1 of the present Volume, or with the first No. of any preceding volume. No subscriptions received for less than a year, and all commence with the first number for the respective years.

CLUBS will be furnished at the following rates:—

TEN COPIES for ..... NINE DOLLARS.
TWENTY COPIES for ..... SIXTEEN DOLLARS.
FORTY COPIES for ..... THIRTY DOLLARS.
ONE HUNDRED COPIES for ..... SEVENTY DOLLARS.

To Agricultural Societies ordering more than 125 copies, THE FARMER will be sent at SIXTY CENTS.

THE CANADA FARMER presents a first-class medium for agricultural advertisements. Terms of advertising, 20 cents per line space. Twelve lines' space equals one inch. No advertisement taken for less than ten lines' space.

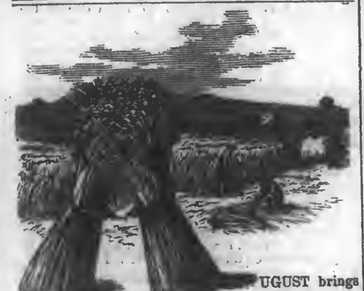
Communications on Agricultural subjects are invited, addressed to "*The Editor of the Canada Farmer*," and all orders for the paper are to be sent to

GEORGE BROWN,
Managing Director.

THE CANADA FARMER.

VOL. V. No. 15. TORONTO, CANADA, AUGUST 1, 1868. POSTAGE FREE.

The Month.



AUGUST brings wane to the summer, and abatement to the heat. These are welcome and pleasant reflections always as July draws to a close, but they are especially so this year. The July of 1868 will be long remembered as unusually hot. For the first fortnight in the month, the thermometer hovered among the nineties in the shade, while drought accompanied the heat, and heightened its apparent intensity. No summer for thirty years past has equalled the present for great and long-continued heat. There have been single days as hot as any during the past month in former years, perhaps hotter, but a whole fortnight of such incessant heat is unprecedented. The mean temperature for the first half of the month, as noted at the Toronto Observatory, was 77°3', upwards of seven degrees higher than the usual average, as given in our July article on "THE MONTH." The highest point of heat reached at the Observatory was 93°4', but as all local influences are carefully avoided there, so as to get the actual condition of the atmosphere, it is not surprising that on the shady side of city streets, with confined air, and radiation of the sun's rays from contiguous buildings, the mercury should have risen several degrees higher. Under these less favourable circumstances there have been days when the thermometer marked from 95 to 100 degrees, and even higher. This unusual heat has prevailed not only throughout the Dominion of Canada, but all over the continent, not even excepting many of the cities on the Atlantic coast, where sea-breezes generally alleviate the miseries of the dog-days. As a consequence, the papers have chronicled a great number of deaths from sun-stroke, while many more have doubtless been caused in some way or other by the great heat. These cases have mainly occurred in cities, and a large proportion of the victims have either been persons of intemperate habits, or have brought on the fatal result by thoughtless exposure, excessive exertion, or too free use of iced drinks. People cannot be too careful during such a condition of the weather. Extreme heat can no more be trifled with than extreme cold. We have met with scarce any instances of sun-stroke or other casualties among the farming community, although it must have been a very trying time, coming, as it has done, at the season of haymaking. Farmers being in general persons of temperate habits, and to a considerable extent accustomed to work in the heat, may account for this circumstance. July has told not only upon human health and life, but upon the crops. Up to the beginning of last month, the season was indeed a model one, giving, as we remarked in our issue of July 1, no conceivable ground of complaint even to chronic grumblers. But the scene has vastly changed within one short month. Wide, and we fear irreparable, damage has been done by the heat and drought.

Leaving now these features that have been special and unusual, we proceed to note the general characteristics and duties of the present month, and as we have been wont to do so far through the year, we transcribe from the "Year Book of British North America" the mean temperatures for August at leading points in the Dominion of Canada.

Stratford	59° 16'
Hamilton	62° 57'
Barrie	58° 31'
Toronto	60° 80'
Belleville	61° 78'
Montreal	60° 18'
Quebec	64° 60'
St. John, N.B.	59° 16'
Halifax	62° 00'

From the above it appears that Hamilton has an average of nearly two degrees greater heat than Toronto the present month, while Quebec is about four degrees, and Halifax between one and two degrees hotter than either Toronto or Montreal.

August work on the farm may be summed up in two words: "Harvest continued." By the beginning of this month, indeed, where the weather has been favourable, and farmers have been duly prompt and pushing, the greater portion of the hay and grain crops will have been secured. Oats will yet be to cut, and this ought to be done before the grain ripens, in order to improve the quality of the straw and prevent the grain from shelling out. When harvest operations are fairly concluded, the tools should be well housed and taken care of, especially the reaping machines, which are costly, and from their construction must suffer greatly from exposure to wind and weather. It is painful to observe what carelessness and neglect are practised in this direction. Farmers who have had a hard struggle to pay for expensive implements, bestow no thought or attention upon them, leaving them perhaps in the open fields, or giving them some partial shelter which is little better than none. This ought not to be. Tools and implements well housed not only last longer, but do better and easier work while they last than those which are subjected to neglect. Root crops will now be so far advanced as to need no more hoeing. Even yet vacant places in the turnip field may be filled by sowing white turnips. They will of course attain no great size, but half a turnip, like half a loaf, is better than none. Those who have not lost faith in fall wheat will improve every opportunity for preparing land intended for that crop. A narrow field along the edge of the woods is the best locality that can be chosen, as there the wheat is less likely to be winter-killed. It is a thousand pities every farm in Canada has not its belts and strips of trees to afford a degree of protection. The country is too bare. Drought in summer, and alternations of freezing and thawing in winter, are the fruits of wholesale clearance. The best seed wheat should be secured, and care taken to get it thoroughly clean. Why should the land be stocked with chess and foul weeds, when a little care and precaution will prevent it? Now is the time that most weeds ripen and scatter their seeds; therefore to destroy them at this period will prevent future increase. It must be *destruction*, however. To cut them up, is often but a half-way measure, from their being left to lie and perfect their seeds upon the ground. To make heaps of them and burn them is an excellent plan. This month is a good time, if there is leisure for it, to underdrain low-lying lands, to dig swamp muck, and expose it to dry, or to perform any operations upon parts of the farm that are wet in the spring and fall. During this month the sheep gad-fly, which causes the trouble in flocks known as grub in the head, hovers about the heads of its victims in order to deposit its eggs about the nostrils. Smearing the sheep's noses with tar, and giving them access to ploughed ground, are recommended as preventives. The garden and orchard will now begin to yield their increase, and the pleasant task of gathering and storing the fruits of the season will commence. Insect troublers may be checked in their depredations by keeping a sharp look-out for them, especially the borer, which lays its eggs about this time. The grub quickly hatches and makes its way into the tree. A wire probe is the thing with which to hunt and destroy this pest. A coating of soft soap at the base of the tree is said to be a safeguard against its depredations. Except in localities where buckwheat abounds, honey-gathering will be pretty much over this month. There is yet opportunity to do something in the way of Italianizing, equalizing, and regulating stocks; operations which must be attended to, if at all, during the summer time. Bees cannot be handled to much advantage when chilly weather comes on, and after the working season is over it is well to disturb them as little as possible.

Stock of all kinds, let it be remembered, will need to be well looked after at this season of scanty pastures and failing springs. It is always poor economy to allow animals to fall off in condition.

The Field.

Summer Fallowing and Green Manuring.

It was a theory in farming, as formerly practised, that after a certain amount of cropping, land required rest, very much as the man who tilled the land, after a period of labour, found it needful to rest. Experience proved that summer fallowing had the effect of restoring fertility to the soil; but it may be doubted if many of our forefathers had any correct idea of the principles in nature according to which this result was obtained. Some vague notion about the land being exhausted, and needing rest, was well-nigh all they knew in reference to the matter. But the scientific explanation of reinvigoration by fallowing is, that in consequence of the exposure of the soil to sun and air, elements of fertility are absorbed, and chemical conditions obtained, which restore productiveness. Land is never exhausted by growing crops upon it; the exhaustion comes of removing the crops without giving back to the soil what has been taken out of it in the course of their growth. If the plant food taken out of the soil by a particular crop were faithfully returned, there would be no exhaustion, and no need of rest. Indeed under such treatment land would increase in fertility, since, to a certain extent, tillage is manure, and a constant stirring of the soil is highly favourable to productiveness. So, also, if the crop were suffered to remain on the land, and there undergo the process of natural decay, not only would there be no impoverishment of the soil, but it would increase in fertility, because growing plants obtain a portion of their nutriment from the air. Again, if, instead of its being left to decay, the crop is fed to animals who consume it on the land, their manure will so far enrich the soil as to prevent deterioration, and maintain the average standard of fertility; while by feeding these animals meal, grain, or oil-cake, in addition to such crop, the land is actually enriched.

Among intelligent and scientific farmers, the practice of green manuring has quite superseded the old plan of summer fallowing. This proceeding consists in the growth of green crops for the express purpose of the vegetable matter thus produced being ploughed under as manure. The most beneficial results have been found to follow this method, and it is every way desirable that it should be more extensively adopted. In explanation of the benefits thus obtained, it is only necessary to refer to a fact mentioned a few sentences back, viz: that plants derive a portion of their subsistence from the air. If the soil were the only source of plant food, the growth of a crop could not add any new material to the land, or augment its fertility. The processes of growth might act beneficially on the soil, as they doubtless do, but nothing would be given to the land except what had been derived from it. But it has been abundantly proved that growing crops absorb a large amount of vegetable matter from the atmosphere, and when this is incorporated with the soil, there must be proportionate enrichment. Nor is this increase of nutriment the only beneficial result arising from the use of green manures. If this were the case, it might be a question whether a like quantity of fertilizing material might not be purchased, and applied to the soil at the same or less cost. There is, however, the mechanical action of green manures to be taken into account, as well as their chemical action. In the case of strong, clay soils, this mechanical action is especially valuable. Such soils, though highly productive, are so dense and compact in their texture, that they are hard to work, and their stores of fertility may be said to be locked up, and to a great extent unavailable. After thorough preparation for a crop, they soon harden again, especially when subject to the influence of dry, hot weather. Ploughing under green manures renders a stiff soil porous and friable, a state of things very encouraging to the growth of roots, enabling them to penetrate the soil more freely in search of nutriment. Sandy and loamy soils are also benefited, especially by their becoming more capable of retaining moisture, which is held by the vegetable tissues thus added to the land. Manure is also more easily retained in such light soils, as the result of this process. Even blowing sands have by this means been so improved, that in process of time superior farms have been formed on tracts of land previously considered barren and worthless.

A crop, to be suitable for green manure, must be of rapid growth, and a greedy feeder on the atmosphere. Mustard, buckwheat and lupin are chiefly used in Great Britain for this purpose. In this country, clover, buckwheat and Indian corn are the best green manures. The last mentioned crop cannot be allowed much growth before ploughing under, or it will become too tall for burial with the plough. Buckwheat is a most excellent plant for the purpose under consideration. It grows very fast, feeds largely on the atmosphere, and is fit to plough under in four or five weeks from the time it is put into the ground. There is no better preparation for fall wheat than ploughing under a luxuriant growth of this plant or of red clover.

The age of the crop at the time it is ploughed in is a matter of much importance. Just before blooming, or when in full bloom, are considered the best periods, and authorities differ as to whether before or while blooming is the preferable time. By all means, however, the plant must not be allowed to ripen and perfect its seed. If this is permitted, the soil is robbed greatly, and much of the fertilizing material consolidated into woody fibre, in which condition it is not so nutritious, or so readily available for plant food.

Another beneficial effect of green manuring, which has led to its being much encouraged in certain localities, is its destructiveness to the wire-worm. This insect, which is one of the wheat farmer's greatest pests, is greatly checked in its ravages by the practice we are commending, and it would be well for those who are troubled with this marauder to try a dose of green buckwheat.

Haying.

BY HENRY WARD BEECHER.

Alas for the poetry of farming! All the songs of milk-maids must be now listened for in the old English poets. The whetting of the mower's scythe is almost over—quite over—on my farm! Instead of that, one hears the sharp rattle of the mower, and sees the driving man quite at his ease riding round and round the meadow, for all the world as if he were out airing! Whereas, heretofore, two acres would be counted a large day's work, now ten and twelve are easily accomplished!

Nor is the contrast less remarkable in all the after-work. When I was a boy I was placed in line, with all the men that could be mustered, to shake out the hay with forks; and after a few hours all hands were called to go over the ground and turn it. To do this rapidly, and yet so that the bottom side shall really come on the top, was no small knack. Now, a tedder, with one man riding, will literally do the work of ten men, and do it far better than the most expert can. Have you ever seen a tedder? I have now a perfect one. The grass rolls up behind it and foams, I was going to say, like water behind the wheels of a steamer. The grass leaps up and whirls as if it were amazingly tickled with such dealings. The result is, that unless the grass is very heavy, and the weather very bad, you may cut your hay in the morning and get it into your barn before night, in far better condition than it used to be when it required never less than two, and generally a part of three days to cure it.

But, I have forgotten the horse-rake. Instead of the old-fashioned, long-handled rake, and the five or six men, pulling and hauling to get the grass into winnows, that same fellow, with that same horse, rides his luxurious rake, and in the fifth part of the time formerly required, puts it in equally good shape. Indeed, haying, if it has lost its poetry, has also lost its drudgery. A man can now manage a hundred acres of grass easier than he formerly could twenty. The only thing that remains to be made easy is pitching on and off the load. It is true that horse-forks have been invented, but I have never seen any that did their work well; and in my barn, at any rate, the old work of pitching and mowing remains; and if you wish to know what fun is, get on to the mow, under the slate roof of my barn, on a hot day, and let Tim pitch off hay, as he will if I give him the wink. You will have to step lively, and even then, you will often be seen emerging from heaps of hay thrown over you, like a rat from a bunch of oakum. And then it is so pleasant, when a man is all sweat, to have his shirt filled with hay seed, each particular particle of which makes believe that it is a flea, and wiggles and tickles upon every square inch of your skin, until you are half desperate!

It is the 2nd of July, and my grass is all cut, and the last load is rolling into the barn while I write. How sweet it smells! How jolly the children are that have been mounted on top of the load; and their little scarlet jackets peep out from their nests while Tim stands guard and nurse. A child that has not ridden up from the meadow to the barn on a load of hay has yet to learn one of the luxuries of exultant childhood! What care they for jolts, when the whole load is a vast multiplex spring? The more the wagon "jounces" the better they like it! Then come the bars, leading into the lane with maple trees on each side. The limbs reach over, and the green leaves kiss the children over and over again. So would I, if I were a green leaf, and not consider myself so green after all! And so the load rolls slowly up the hill. There is no such thing as momentum in an ox. He is always at the dead pull and at the very hardest. But the children like it! The slower, the longer the ride! Let them take all the comfort they can. By and by they will be grown, and own fine carriages, and roll in style through the streets. But there is many a fair face that rides in a silk-lined coach, with a sad heart, and would go back if she could, oh how gladly, to the joyous ride on a load of hay!—*N. Y. Ledger.*

The Spruce for Hedges.

To the Editor of The Canada Farmer:

Sir,—Many of your correspondents' letters are so interesting that I wish to furnish my quota, especially about hedges.

I quite agree with Mr. J. Nicholson about trimming hedges, viz., that the triangular form should be always observed. A hedge trained in this way must be thick at the bottom, the rule being—one foot high, one foot at the base, and so on to six feet.

If this principle is a correct one, the question then comes, what form of tree will yield most easily to such conditions? The thorn is always trying to get toppy, and consequently thin at the bottom; in fact most thorn hedges, if turned topsy turvy, would make good hedges. I also find all classes of domestic animals feed greedily on the thorn shoots; another objection I make is that early in the year the hedge looks thin, until the leaves come out. I have, therefore, abandoned thorn hedges to adopt the Spruce Fir. This tree, if planted two feet apart, comes up to my idea of what a good hedge ought to be; it readily conforms to the shape required, viz., the triangular; it looks tremendously strong; no animal eats it, and it is handsomer in winter than in summer, besides growing quicker. I know of no insect which destroys the Spruce Fir. I have about twenty acres of Fir hedge planted on my farm; I clip them with shears as there is little or no trouble with them. The thorn, on the contrary, is always trying to bother us, and it is the work of a careful man or the master himself to keep them in bounds.

Spruce Firs are delivered on my farm, two feet high, at five cents each. I always prefer those grown in a field to those brought out of a wood. Fir hedges are used on the railways in Switzerland as thorns are used in England.

W. RHODES.

Sillery, Quebec, 20th June, 1868.

New and Easy Method of making Maple Sugar.

A correspondent of the *Mark Lane Express* referring to the principle of pneumatic evaporation applied by the Northern Tartars in a very simple and efficient way, during the winter months, in the preservation of milk, finds in it a novel and short-hand method whereby Canadians may make maple sugar. The Tartars place milk in shallow pans, and expose it to the cold winds during frost. In a short time, a dry, white, crispy substance is found on the surface, which is carefully scraped off and put into bottles. This process is repeated until all the watery portion of the milk is evaporated, and a sweet white substance, which is essentially *sugar of milk*, is thus obtained, which may be kept any length of time, in any climate, if kept dry. "This plan" says the writer, "though not practicable here, might be applied to the evaporation of the sap of the maple in Canada, and would produce excellent sugar at a trifling cost." Notwithstanding the assured confidence with which the above prescription is given, there being no "if," "but," or "perhaps" to qualify it, we doubt if anybody in Canada will have enough faith to try it. How very easy it is to theorize! Did ever anybody see "a dry, white, crispy substance" floating on the top of a trough-full of maple sap, exposed to "pneumatic evaporation?" Without consulting a manual or professor of chemistry for the scientific explanation of the difference between the two liquids, it is quite enough to know that sugar scales were never found formed on the surface of maple sap, and that the only method of obtaining the sugar is to evaporate the sap by applying artificial heat.

The Cultivation of Land.

Mr. Jackson, M.P. for North Derbyshire, attended the anniversary dinner of the Norton Farmers' Club and District Agricultural Society, held at Staveley, and gave an amusing account of his experiences in agriculture. The honorable member, on the subject of the draining of land, observed that he once had a field of thirty acres, and it grew nothing else but large camomile flowers—that was, large yellow daisies. They were so thick and so hard that a cannon ball if fired into them would have rebounded. Well, at last he commenced draining, and he drained four and five feet deep, the distance between the rows being eight feet. Whilst the field was being drained the season overtook him, and although he ploughed as fast as he drained, he was unable to sow more than half of the thirty acres. He was speaking what was strictly true when he told them that the money he received from the first crop paid the cost of the drainage of the entire field; therefore, he was not a loser by it, but a great gainer, because during subsequent years he reaped the beneficial effect of the land being drained. Some time ago he was fortunate enough to produce forty-two tons of carrots from one acre. He trenched the soil about three feet deep, and at the bottom of the trench put a quantity of good stable manure mixed with guano. He then transplanted his carrots, and for a month they hung down their heads as if there was no life in them. At last they began to smell good stuff below, and the result was they went down with a vengeance. After some time he was able to draw carrots as long as his arm, and as thick as the thickest part of it. The next year he had a similar crop of carrots, followed by a splendid crop of potatoes, and then by a good oat and clover crop—all without any additional manure. If they only brought capital and science into play, it was almost impossible to over-estimate what could be done with land; and he did not know anything that would pay a man better than to purchase land for agricultural purposes. Mr. Jackson then proceeded to recommend farmers not to pay so much attention as they were doing to the production of cereals, as he said there were other countries in which they could be grown where land was cheaper and the sun stronger; but other countries could not produce such beef and mutton as England could, and he advised them to make the breeding of beasts and sheep their principal study. The hon. member recommended increased attention being paid to the rearing of poultry, as he said £2,000,000 were spent by this country every year for eggs and poultry obtained from the Continent, when we ourselves might produce all that the country required.—*Farmer* (Scottish).

The Difference between Ploughing and Cultivation.

Mr. Mechi says deep ploughing may be ruinous where deep cultivation would be beneficial. This apparent paradox may be easily explained:—Where the land, just below the regular ploughed line, is undrained, panned down, and consequently has never been subjected to the ameliorating influence of aeration by exposure, it is, in too many instances, absolutely poisonous to young plants. I know of so many cases where, by at once ploughing up and bringing to the surface four or five inches of raw subsoil, the land has been rendered much less productive for several years, that I warn my amateur farming friends against committing such a costly error. The young growing plants cannot thrive, in the beginning of their growth, in such unprepared mass, and, consequently, are enfeebled before their roots reach the good buried top soil. That able agriculturist, the late Mr. Smith, of Deanston, wisely recommended that the subsoil should be allowed to dry a little after being drained before even subsoiling was attempted; and that kind and enlightened man, the Rev. Samuel Smith, of Leis Weeden, ploughed his top soil together, and then worked his manure into the uncovered subsoil, leaving it bare for a time, and then re-covering it with the surface soil. When I deeply cultivate, I plough the top soil, and follow in the same track with another plough (minus its breast or mould board): the next turn of the first plough then covers up this raw subsoil. In this operation a portion of the subsoil gets gradually mixed with the surface soil, and thus my staple is gradually increased with benefit to the crops. My experience teaches me that from ten to twenty years will hardly suffice to bring into a suitable condition some of our tenacious plastic clay subsoils. It is on these grounds that I should, in the case of using steam power, commend the use of the grubbers, or cultivators, that stir the soil deeply without bringing much of it to the surface, and that it should be a gradual deepening instead of tearing up at once great masses of the subsoil. I have never seen any implement so suited to the purpose as that which steam ploughed a portion of my clover in 1856, in the presence of a large company. That deep cultivation showed its good effect for several years. Fowler's plough was supplemented by Cotgreave's sub-soil plough. They were attached, so that as they moved along one furrow slice laid under the other, the top soil being laid on the top of the other; and yet, strange to say, I never have seen this used since. The fact is that this double ploughing takes much power, and cannot be hurried over, but it is the proper and most profitable mode. Many farmers have been ruined by rashly burying their best soil, and covering it with several inches of raw subsoil. There may be some subsoils sufficiently wholesome to permit of their being suddenly brought to the surface. In many cases ploughing is objectionable, leaving long unfilled spaces obnoxious to the roots of plants. The cultivator has many advantages.

The Peck per Acre.

To the Editor of the Mark Lane Express.

Sir,—The peck of wheat per acre sown the second week in November looked like a fallow all winter, but is now, after hoeing, branching abundantly, and my labourers predict that it will be as good or better than the rest of the field sown thickly with one bushel per acre. Every year I sow half an acre with half a peck of wheat, in the midst of a thicker sown crop, putting it in the same day and under the same circumstances in the various fields, as they come in rotation. By this means I arrive at safe conclusions, and I would strongly recommend my agricultural friends to follow my example, by thus experimenting on a small and uninjurious scale. It would abolish many prejudices, and they are bound for their own interests to ascertain the most profitable quantity of seed. My four years' trials have resulted in 58, 57, 36, 36 bushels of wheat per acre, the two first good wheat years, the two latter unfavourable. I still continue to drill 4 pecks of wheat, 6 pecks of barley, 8 pecks of oats, as my general sowing—a trifle more on the light land; but I am getting more and more convinced that, with high, clean farming, and the drill, we may, in Essex, reduce our wheat to 2 pecks. On light lands we need not fear wireworm, if we use 6 bushels of salt per acre about February, or early in March. By having our drill-cups and wheels arranged like those of Mr. Hallett, at Brighton, we can put in very small quantities of seed. It does amaze me to read that 7 bushels per acre of oats are still sown in Scotland, and that this sowers pride themselves upon putting in only 5½ bushels! I presume that this is done broadcast, and the mea sure a Scotch acre. I am satisfied, however, that such a system can never result in such crops as we generally grow on this farm—say from 9 to 13 quarters of black oats per English acre.—I am, sir, yours,

April, 1868. J. J. Mechi.

Good Farming, High Farming.

Good farming is sometimes high farming, and sometimes not. Ploughing under a crop of clover for wheat is frequently good farming, but it is anything but high farming. Summer-fallowing is often the best and cheapest way of cleaning and enriching land, and in such case is good farming, but it is never high farming. High farming would summer-fallow the land, and have a heavy crop growing at the same time.

The market gardens around New York afford excellent examples of high farming. Read Henderson's interesting book on "Gardening for Profit," and you will get an idea of how much produce can be raised on an acre of land. They employ a working capital of $300 an acre; underdrain thoroughly; use from 50 to 100 tons of manure on each acre every year; have two, three, and four crops in succession during the season on the same land; never let a weed show itself; pay from $100 to $300 an acre rent and taxes, and make a handsome profit besides. This is high farming. They have to pay an enormous price for the land, and they *must* farm high or not farm at all. They could not afford to let their land lie idle a year in order that they might summer fallow, or plough under a crop of clover. Where land is worth only $50 an acre, we can afford to adopt a slower method of enriching it than when it is worth $500, or even $200 an acre.

I can afford to spend $30 an acre in underdraining my farm in Western New York, but it is very questionable whether $30 an acre can be profitably spent in draining a farm in a section of Iowa, where good, dry land could be bought for $10 an acre. Where corn is worth $1.25 a bushel, it may pay to expend 25 cents a bushel in grinding and cooking it for the hogs, but where corn is worth only 35 or 40 cents a bushel, it would hardly pay to expend 25 cents for the purpose.—*J. Harris, in American Agriculturist.*

Ashes for Grass.—Mr. David Goodwin, of Arnprior, sends us a fine specimen of Timothy, with the following note:—"Enclosed I send you a stalk of Timothy, over six feet in length, grown on my farm, Township of McNab, County of Renfrew. It shows the great value of wood ashes as manure, as it grew on the border of a meadow where the fence was burned last spring, and the fire ran among the old grass."

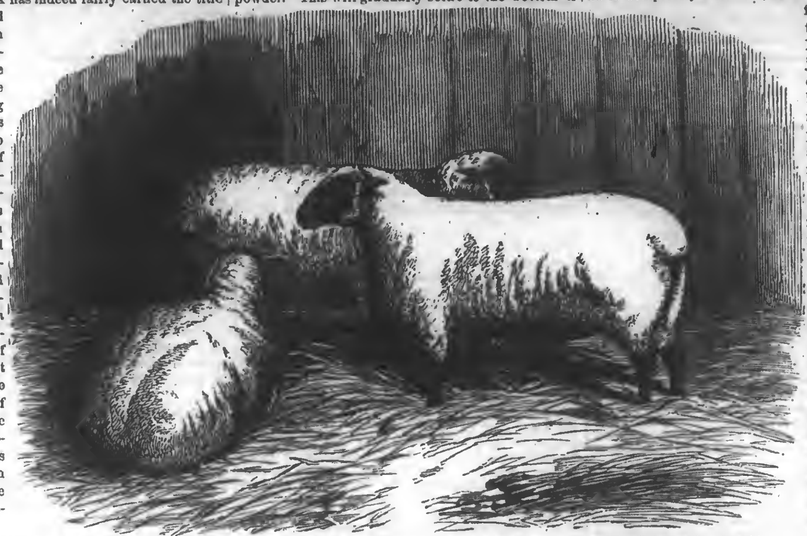
Salting Wheat.—A correspondent in the *Colonial Farmer* recommends the addition of salt to wheat as soon as it is threshed, adding half a pound of salt to a bushel of wheat and mixing them in the bins. He says that wheat so treated is better preserved than by the ordinary method; that it does not lose so much in weight or volume, that it makes more and better flour; and that when used for seed it is not liable to be attacked by weevil (qy. midge?) The correspondent referred to has tested the plan, he tells us, for eighteen years with unvarying results.

Haying in "Catching Weather."—Last year the weather was characterized as "catching"—almost any body can make hay when the sun shines, but the problem may be presented to make hay when it does not shine. With the mowing machine, tedder, horse rakes, and hay taps, an active man of fair judgment may succeed, with a mere modicum of the direct heat of the sun. The principle is continuous drying. The lack of sunshine must be made up by stirring, if the atmosphere is a drying one, and here a good tedder will be found most useful. Long exposure of clover to the hot sun is ruinous; the heads and leaves will fall off, and these constitute the best part. Grass containing clover should be dried rapidly, until thoroughly wilted, and while still green and hot, cocked up. If it has a little sunshine when first cut, it will cure in ordinary catching weather in the cocks, covered with hay caps, provided it can be opened out and shaken up now and then. The hay will be surprisingly green and good, and it will not require much labor to make hay in this way.—*American Agriculturist.*

Stock Department.

Hampshire Down Wethers.

The accompanying illustration, taken from the *Farmers' Magazine*, represents a fine group of Hampshire Down wethers, the property of Mr. W. D. Canning, of Elston, Devizes, England. Some account of this valuable breed of sheep will be found in our last volume, page 37, with an excellent engraving of the animal that took the prize in this class at the Provincial Exhibition of the preceding year. In reference to the subject of our present illustration, the June number of the *Farmers' Magazine* says:—"These wethers were at all points one of the best pens of sheep exhibited at the last Smithfield Club Meeting. Mr. Canning's flock has indeed fairly earned the title of "*Improved*," and his sort has been deservedly appreciated alike in the market and the show-ring. During the last few years the Elston sheep have taken ten of the Royal Agricultural Society's premiums, six of which were first, with ten from the Smithfield Club, in equal proportions of first and second. Mr. Canning was also a winner at the Salisbury Meeting of the Bath and West of England, the only occasion of his entering the ranks of that Society, while he has of course taken from time to time any number of local premiums.



This deservedly famous flock of Improved Hampshire Downs will be sold at Elston in August."

The Chemistry of Respiration

Having already considered the mechanism of breathing, we come now to examine the chemistry of the process. By this phrase is meant the changes in the air and blood that result from the contact of the two in the lungs. The air we breathe is composed of two principal elements, oxygen and nitrogen, in the proportion of one-fifth of the former to four-fifths of the latter. There is besides a very small portion of carbonic acid present in the atmosphere; but the ordinary proportion does not amount to more than four-parts of this gas in ten thousand parts of air. A varying quantity of watery vapour is also dissolved and mixed with the air. Such is the composition of air as it is inspired or drawn into the lungs; but the breath which an animal expels from its lungs is found deficent in the proportion of oxygen, and contains in its place a quantity of carbonic acid. The amount of this gas given off in each act of breathing is indeed very considerable. Taking the human lung as an example, it may be stated as a general average that, under ordinary circumstances, the quantity of carbonic acid exhaled into the air breathed by a healthy adult man amounts to 1345 cubic inches, or about 636 grains, in an hour. According to this estimate, the weight of *carbon* excreted from the lungs is about 173 grains per hour, or eight ounces in the course of twenty-four hours. The quantity of carbonic acid exhaled from the lungs of larger animals, such as the ox or horse, is considerably greater, and even in the case of smaller animals, as sheep, which are often collected together in large numbers, it will readily be understood that the air about them must soon become loaded with carbonic acid unless it is changed by a free ventilation.

The presence of carbonic acid in the expired air is easily shown by a simple experiment. If we breathe through a tube into lime water, that fluid very speedily becomes charged with carbonate of lime, and assumes a milky appearance. The cause of the change is that the carbonic acid from the lungs unites with the lime dissolved in the water, forming carbonate of lime, which being very sparingly soluble, becomes diffused through the liquid as a fine powder. This will gradually settle to the bottom if the water is allowed to stand. Besides the carbonic acid expelled from the lungs, a considerable amount of watery vapor is exhaled in breathing.

The foregoing are the chief effects produced on the air by respiration. We cannot here very minutely explain the changes which the blood undergoes, but will merely state the principal alterations to be observed in this fluid during the same process. The blood, as already explained in the previous article, when it returns to the heart after completing the circuit of the body, is altered in colour, being dark instead of bright red. This change of colour is due to the presence of carbonic acid distributed or dissolved in it. As the blood permeates the minute vessels of the lungs, every drop of it is exposed to the air, and here it parts with its carbonic acid, and absorbs instead the oxygen of the air. This restores the bright color of arterial blood, and the change renders the fluid again fit to circulate through the body. Nitrogen is also absorbed and given off, but of this it is not necessary for our present purpose to take any account. The fresh portion of oxygen imbibed is probably in part immediately combined with some of the constituents of the blood, but most of it is merely dissolved, and carried in the circulation to various parts of the body, where in the ultimate capillaries it unites with carbon thrown off from the tissues in the constant process of change going on, thus forming carbonic acid; for this gas, it is scarcely necessary to inform the reader, is a chemical compound, in definite proportions, of oxygen and carbon. The carbonic acid thus produced is carried in a state of solution by the blood to the right side of the heart, and thence into the lungs, to be exhaled, and replaced by a fresh portion of oxygen.

It is absolutely necessary that the venous blood charged with carbonic acid should undergo this change before it passes again through the body. Without this chemical alteration it is a fatal poison to the system, and nature indeed resists its circulation through the body. For if pure air is not admitted into the lungs, the dark blood will scarcely pass on its course; the lungs, therefore, are gorged with blood, the left side of the heart becomes empty, and the right side distended and overfilled; what little blood returns from the lungs into the left side is venous, and this being sent to the brain, augments the mischief, till both the acts of breathing and the beating of the heart very soon cease altogether. If air is completely excluded, as in drowning, a very few minutes serve to extinguish life. In the human subject the contraction of the heart ceases in less than five minutes after complete submersion, and persons are rarely saved if they have been under water more than four minutes. The instances in which recovery has taken place after a longer immersion are probably to be explained by the occurrence of fainting at the moment of the accident; for, with the circulation thus enfeebled, the deprivation of air may be endured much longer than it can while the blood still circulates quickly and accumulates carbonic acid.

It is obvious, then, that carbonic acid, mixed in any but the smallest proportion with the air we breathe, is highly poisonous. Its presence in even small quantities is deleterious, for it is only when the air is perfectly pure that the proper exchange of gases will take place. If carbonic acid already exist in the air, a much smaller amount is given off by the lungs, so that the mischief very rapidly assumes threatening and dangerous magnitude. We learn also, from the manner in which the ordinary gaseous elements of the air are absorbed by the blood, with what facility any impurities can by the same means be introduced into the vital fluid, and work out according to their nature, slowly or quickly, but most surely, their injurious and often fatal effects.

From these considerations the necessity of thorough and efficient ventilation becomes obvious. It is not necessary that the air should be vitiated to the point of suffocation to become a source of disease. The breathing of a single animal soon renders an apartment impure, and unless fresh oxygen—that is, fresh air—is supplied, and the carbonic acid and other impurities dissipated, the neccessary change in the blood cannot be duly effected, morbid matter is introduced into the system, and disease in some form, if not a speedy extinction of life, will assuredly follow. There is indeed no more certain method of infecting poison into the blood than by the air we breathe, which is none the less potent because impalpable and unseen.

The Summer Management of Stock.

It is a difficult matter on a considerable holding to keep all varieties of stock going on satisfactorily, to ensure their getting food suitable for them in quantity, and of a quality which will prove fairly remunerative; to prevent waste; to ward off causes of accident or disease. Properly to arrange all this, requires some generalship and some experience. Young farmers with a fair command of stock often fall into the serious error of getting overstocked; in a dry season like the present, many good managers are apt to discover that they also have too many mouths. Cattle and sheep always do best where they can have a change of grazing once or even twice a month; as we have often insisted on, a given acreage of clover grass or vetches will produce a greater weight of meat if the food is brought to the animals, instead of being walked over and spoilt by them. With sheep the penning system is the most economical, and has the great advantage of getting the land evenly manured, and making also the best of the cake or other purchased food. Even where sheep are not constantly confined to the pens, it is good practice to enclose the flock during the night. The food is thus kept fresh, and less of it is spoilt. The night pen, which should be moved several times a week, should either be in the same field in which the sheep graze during the day, or in a contiguous field of clover, vetches, or the like. By the adoption of the system of pens, and by increasing the quantity of purchased food, a bad season may be successfully encountered, and a very heavy stocking carried through without loss. In the grazing or penning, whether of cattle or sheep, it is unwise to have too many animals together. One hundred sheep is quite enough to have in one pen. It is important to place together those animals which are about the same age, or state of progress, and that will best agree.

Horses are thriftless inmates of good pastures; they are apt to disturb other stock; they graze down closely the best of the keep, and their summer management is often a difficult question. We prefer the eastern counties' system of keeping the cart-horses of the farm in lots of two or three together in divided yards, which, at this season, are usually kept empty. Here they are supplied with rough grass, cut about the pastures, or, where that is insufficient, with clover or vetches. If turned out at all, they had better be secured by the foreleg, as is done throughout the midland counties of England, and with an iron peg and stout chain confined on the roughest parts of the cattle or sheep grazings, or be similarly tied upon vetches or clover.

For all animals it is most important to look to quantity and quality of the water supply. A good supply of pure, fresh water is, in hot, dry weather, quite as essential to thriving as food itself. With access to a good spring, we often find young stock make wonderful progress, even when the pastures are extremely bare. Running streams are preferable to stagnant pools; but in many clay and fen countries, these pools are the only sources of water during a dry summer. Where pools are the sources of the water for stock, great care should be taken that all mud should be removed almost daily from the points of access to the watering place, so that all stock, but more especially the sheep, may get at the water readily. Sheep will often want water for days rather than walk over rough, poached or muddy ground to procure it. When sheep do not come readily to the pools, troughs should be formed without delay, and fitted from the pools with a convenient hand pump, or a supply brought daily in a water-cart. From being short of water in the summer or autumn, hundreds of young sheep pine and die during the subsequent winter.

During hot, dry weather, the dairyman has his special difficulties to contend with. The cows, instead of eating as much as usual, lie lazily in the shade, or worse still, gallop about, tormented with flies. A sponging over in the morning with a weak solution of carbolic acid, is recommended to abate this nuisance of the flies. In very hot weather milking cows are much better kept in the house during the day, and only grazed at night. A little beanmeal or cake, with some cut food twice daily, will sustain the condition of the herd, and the yield of the milk. In thundery weather the milk is liable soon to get turned, and within twenty-four hours, or better still, in twelve hours, it should be disposed of, skimmed, or set aside for calves or pigs. Ten grains of sulphate of soda, if mixed with each gallon of milk whenever it is brought in from the cow, will greatly retard fermentation.

Lambs after weaning will require for some weeks great care alike in feeding and general management. It is better to take the ewes from the lambs than to move the lambs from the ewes, as is often done. Accustomed to their grazing, their water supply, and other surroundings, the young lambs sooner become reconciled to the separation from their mothers. If they are not already receiving any artificial food, three or four ounces of linseed cake will greatly help thriving, and ward off disease. They should be "run thin;" when put in a fresh field, they should be daily driven to the watering place; little time should be lost in having them dipped, and before the middle of September they should be on roots.—*North British Agriculturist.*

Sheep Combing.

The new system introduced into Australia has enabled those that first followed it to obtain from 9d. to 2s. per fleece more for the clip than they formerly did. The sheep are collected into a long, narrow pen, and when standing close together water from a hose is spouted all over their backs; after this has damped the outside of the fleece, they are advanced forward gradually to a vat filled with water, about the temperature of 70 degs., into which some soda has been put. They swim across this, and are led into a narrow passage from 10 to 20 yards in length and 2 or three feet wide and 3 feet deep, and walk up a gangway, and collect in another pen, whence they are taken to the spouts, which consist of a stream of water about the length of the sheep falling in a sheet about one inch thick. They are held a minute or two under this, being turned all round, and then sent up another gangway to the dripping yard. The wool, when thus washed, is beautiful and bright, and neither harsh nor feeble to the touch. This country has great advantage over Australia as to spout washing, for in a flat country steam or other power is required to raise the water; but here, especially in the pastoral districts, by damming up a burn the requisite fall can be had, and where it cannot, the travelling threshing engine could be taken advantage of, and those who own these could purchase pumps, tanks, &c., and heat the water from the boilers for soaking with, as well as raising that required for spouting.—*James Melvin, Bonnington, Ratho, in London Farmer's Journal.*

Challenge Colt.—Mr. George Addison, of Vaughan, sends us the following communication:—"Mr. Henry Russell, of Etobicoke, has purchased a colt from Mr. George Addison for one hundred and ten dollars. This colt was sired by 'Old, Hard Fortune,' and its dam is the celebrated mare, 'May Flower,' and it is now only eight weeks old. It is pronounced by experienced judges to possess the finest points of any colt in Canada. It is Mr. Russell's intention to exhibit this colt at the principal exhibitions and fairs in the Province, so that owners of other colts may have a chance of testing whether it really is the 'best colt in Canada.'"

Cruelty to Horses.—A correspondent of the *Norfolk Chronicle* has addressed the following observations on the use of the bearing rein, to the editor of that journal:—Amongst those who have the care of horses, few appear to be aware of the pain they inflict on this useful animal by the injudicious use of the bearing-rein. Let any person place his head in the easiest position he chooses, and then have it strapped there two or three hours, he will then have a little experience of the pain the bearing-rein inflicts. Instead, however, of the easiest, let his head be forced into an unusual position and fixed there several hours, the sufferings of the horse from such restraint will be strongly impressed upon him. The pain thus caused is not the only evil. The horse is unable to act freely, he is prevented throwing his weight into the collar, and forced to draw by his muscle what he would do more easily by his weight. Horses not so confined draw greater weights more readily. The reason is evident. At many of the railways horses are worked without bearing-rein or blinders. Observe the heavy loads they draw, and the manner they throw their weight into the collar. Few persons who have witnessed the working of these horses will dispute the worthlessness of the bearing-rein, except for injury. There are other objections to its use. It spoils the horse's mouth, and often his temper, causing uneasiness and fretfulness, as may be noticed by frothing at the mouth, and expression of the eye. It is painful to witness this noble animal subject to needless torture, and I hope the subject may attract the notice of those who are owners, as well as others who have the care of horses.

Veterinary Department.

Diseases of the Horse's Foot.

In a former number we mentioned that during spring and the hot months of summer injuries and diseases of the horse's foot are very common indeed. As a consequence of fast driving and overheating, the sensitive lamina frequently becomes inflamed, and gives rise to very alarming and painful symptoms. The horse is suddenly attacked, he suffers extreme pain, and when forced to move he does so with the greatest reluctance; he stands with his fore feet placed well forwards, and he brings his hind legs well under his body, so as to take the weight off the front feet; and from the position in which he places himself for relief the casual observer is apt to think that the loins are the seat of the disease; whereas the complaint is entirely in his front feet. The pulse is quickened, and in many cases the breathing is heavy and laboured; there is increased heat around the coronet, and the arteries going to the foot will be found to be throbbing violently. When made to back, the horse pulls his fore feet along the ground, and endeavours to throw the greater part of his weight upon his hindquarters. These urgent symptoms require immediate treatment, for if relief is not afforded in three or four days from the commencement of the attack, the disease is apt to terminate in permanent lameness. The shoes should be removed without delay and the feet enveloped in large poultices of bran or linseed meal; wet bandages should also be applied to the legs as high as the knee-joint; the horse should be placed in a loose box or roomy stall, and allowed plenty of clean bedding, as the more he lies the more favorable it is for his complaint. A plentiful allowance of bedding will prevent chafing of the loins and sides, during the hot weather. He should also have a moderate dose of purgative medicine, and if the fever is great, ten drops of the tincture of aconite, every three or four hours, will afford relief. When the stiffness disappears and the horse walks freely, the shoes should be re-applied, and he may be kept standing in moistened clay for three or four hours daily.

As another result of extreme heat, a solution of continuity between some of the fibres of the hoof is a frequent occurrence, and this is known as sand-crack, and so called because it is said to be most common amongst horses raised in hot sandy districts, the heat of which tends to give the feet a predisposition to this disease. Sand-crack is oftener met with in the fore feet than in the hind ones, and in the former the crack is usually situated in the quarters, whilst in the latter it generally occurs in the front of the hoof. In either case the crack may completely penetrate the thickness of the hoof, and as a consequence the sensitive parts underneath are injured and the affection becomes very painful, and of course gives rise to extreme lameness. The crack may extend from the coronet to the sole, or it may be confined to one-half of the wall. Sand-crack is very easily detected. At first a small crack will appear at the coronet, and will gradually extend downwards, becoming larger and larger, and frequently, after rapid exercise, blood will be noticed oozing through the crack, and there is considerable motion between the divided edges when the foot comes on the ground, thus setting up irritation, and frequently matter will form, which if not allowed to escape, will give rise to quitta. A complete crack in the hoof will not re-unite; but the new formed horn must grow from the coronet. In the treatment of this ailment, the shoe should be removed, and the divided edges pared. If matter has formed it must be allowed a free exit, and a poultice of linseed meal should be applied. When all irritation is removed, apply a shoe, so as not to press upon the affected quarter, and therefore, in many instances a bar shoe is most suitable. The growth of horn is also hastened by the application of a blister on the coronet, above the injured part.

The Dairy.

Manufacture of Whey Butter.

A recent number of the *Utica Weekly Herald* contains an account from the pen of Mr. X. A. Willard of a visit paid by that gentleman to a cheese factory in Lewis County, N. Y., where butter is made from whey by a method known as the "Riggs and Markham process." The factory in question is carried on by Mr. Homer C. Markham; works up the milk of 250 cows, (about 5,000 lbs daily,) turns out some 500 lbs. of cheese per day, and manufactures from the whey sixteen pounds of butter daily. Of this butter, Mr. Willard, no mean judge, says, that it is a decidedly good article, not equal indeed to first-class Orange County butter, but a marketable article, better in flavour than half the cream butter found on hotel tables, so excellent indeed that nobody would suspect it of being made from whey. In reference to the quantity obtained, Mr. W. remarks that the cheese-making at Mr. Markham's factory is most careful and thorough, so that it is only fair to conclude that the whey is of poorer quality than what is usually obtained at factories. The following is a detail of the method by which the butter is made at this factory:

"The whey is drawn directly from the cheese vat into the heating vat, which stands in an adjoining apartment and below the cheese vat, so as to allow the whey to be readily run from one vat to the other. The heating vat has a copper bottom, and is placed over a brick arch. It is preferred that the whey be drawn sweet. Then, for every fifty gallons of the sweet whey, one gallon of sour whey is added. If the acid is not sharp, one pound of salt is incorporated with it. Heat is then immediately applied to the mass until it indicates a temperature of 175° to 180°. When the cream rises, it is skimmed off and set in a cool place and left to stand till next day. It is then churned at a temperature of from 56° to 68°, according to the temperature of the weather, and is then worked and salted in the ordinary manner of butter making. Usually, under this process, five hundred gallons of whey will make twenty pounds of butter. On the day of our visit to the Markham factory, no acid was added to the whey, but a little salt added to the mass when the temperature had reached 160°. When the thermometer indicated 170°, the cream commenced rising, and was soon thrown up, and Mr. Markham commenced dipping off soon after the cream commenced rising, or before it became thick and hard. He dipped with a broad, square tin shovel with a short handle, dipping down into the whey and removing a portion of it with the cream. He dipped into a large pail, and when full emptied into a large milk can having a faucet at the bottom, and which stood in one corner of the room. This can was nearly or quite filled with the cream and whey. Mr. M. lets it remain in the can to cool off, and the next morning, just before churning, the faucet is opened at the bottom, and the whey which has separated from the cream drawn off. The cream is then taken out and put into the churn, and churned by dog-power. Mr. Markham's factory is a model of neatness, and both the whey and cream are kept clean and free from specks. The butter, therefore, contains no more impurities than the cheese."

The manufacturer claims that his butter, if properly stored in a good, sweet cellar, will keep for a long time. Mr. Willard, while doubtful as to its keeping qualities, justly observes that if it will keep long enough for present use and for this purpose is equal to the great bulk of butter made for the table, it would be a vast saving of money to dairymen if this process could be generally introduced.

"On the assumption that the whey from 250 cows gives fifteen pounds of butter per day, a factory of 1,000 cows would turn off sixty-four pounds of butter, while the cost of apparatus and making for the large number of cows would be but a trifle more than the smaller number. Sixty-four pounds of butter, say at an average of thirty cents. per pound, would amount to $19.20 per day, and if only four months be taken, say from the 20th of May to the 20th of September, or 120 days, we have $2,304 for a single factory."

As to the value of the whey for feeding purposes, after being deprived of its oil, the cooked state of the whey is thought to go far toward counterbalancing the loss of the oil. Mr. Markham believes it does more, and says that his experiments in feeding hogs on each kind of whey prove this. Be this as it may, it certainly will not pay to feed hogs with butter at the present market price of the article. An equal weight of bran substituted for the butter, would certainly make the whey more nutritive than with the butter left in it. As to the labour and cost of manufacturing butter from whey, Mr. Willard says:

"The apparatus is very simple and inexpensive—a vat with copper bottom over a brick arch would be the main outlay. For a large number of cows we presume some extra labor would be needed, but such additional labor, with proper conveniences, can not be much. At Mr. Markham's factory, Mr. M. has but one assistant—a girl. They two do all the work about the factory, manufacturing both the cheese and butter. Fuel, too, is required. Of the amount some estimate may be made from the quantity used by Mr. M., a cord of 18 inch wood (hemlock slab) lasting eight days. We could not see that the labor of extracting the cream was of much account. The whey runs from the cheese vat to the heating vat simply by arranging the pipes; a little fuel is thrown under the heating vat and the cream skimmed off. It can all be done by those attending the cheese vats How much additional labor will be required to churn and pack the butter, dairymen generally can estimate. The cream, we were informed, readily churned into butter. Occasionally, if gathering the butter is delayed, it is readily obviated by using warm water in the churn, say at a temperature of blood heat."

We have transferred to our columns the leading points in reference to the process of making butter from whey, and we commend the matter to the attention of Canadian dairymen. Further particulars may doubtless be had by addressing Messrs. Riggs and Markham, Turin, N. Y.

Hunting for the Cows.

Many of our farmers have wasted years of valuable time just because they did not teach their cows to come home at night. Any one who has ever lived or travelled in the country will remember the familiar "Co-bos," "Co-bos," of the farmer's son, or hired man, as they endeavour to coax the cow from the woods or the tall grass in the great pasture. We have had a little experience in these matters, and well remember how many times we have waded through the brush and bogs looking for the cows, and boylike, we thought them dreadful contrary animals. But we have lived long enough to learn better, and now think that the biped was the more contrary animal of the two. Boys, we will tell you a secret that will save you a great deal of trouble, and it is this: Just sow a few rows of corn in drills, where it will be handy to the milking place, and every time the cows are driven up at night, or in the morning, give each one a good armful of the fresh cut cornstalks, and our word for it the cows will always be on hand at milking time. Besides this, they will give more milk, and forget to kick over the milk pail, even if you do whistle a little too loud.—*Weekly Sun.*

Milk from a Calf.—I have an Alderney heifer, eleven months old, that I accidentally discovered, a week ago, had milk. I have drawn it daily since, and the quantity increases. Can any of your subscribers inform me if there is anything very strange about this, or whether it will be any injury to continue to milk her?—*S. A. J. in Co. Gent.*

Honesty.—A boy, whose honesty is more to be commended that his ingenuity, once carried some butter to a merchant in a country village to exchange for goods. The butter had a very beautiful appearance, and the merchant, desirous of procuring such for his own use, invited the boy to bring him all the butter his mother had to spare. "I think," said the boy, "she can't spare any more, for she said she would not have spared this only a rat fell into the cream, and she did not like to use it herself."

Collett's Antiseptic.—The attention of cheese-makers and others is directed to Mr. Collett's advertisement in the present issue. We believe that the rennetts which he supplies are of first-class quality. We have also a high opinion of the antiseptic preparation that he advertises. Practical experience and chemical testimony concur in commending its use for a variety of purposes besides that mentioned in the advertisement. It has been successfully used in preserving meat fresh, both in this country and in England.

The Apiary.

Management of Frame Hives.

Now that movable-comb or frame hives are being extensively introduced, it may be well to give a few hints respecting the management of bees in such hives. Frames are put in hives in order that the bees may build their combs in them, so that the combs may be removed at pleasure. Now, it is thought by some that all that is necessary to do is to put the bees in the hive, and pay no further attention to them until they wish to remove the combs, when they expect to find them nicely filled in the frames, touching each other at no point, and as easily removed as the frames would be if empty. Such persons are sure to be disappointed. On opening the hive they not only find the combs attached to each other by bars, often appearing like a solid mass, but even some of the combs built across from one frame to another. Now, it should be remembered that no hive, can be constructed that in every case will ensure combs built exactly straight in the frames without any attention on the part of the bee-keeper. But with a well-constructed frame hive and proper management, straight combs may always be secured. In the first place, before the bees are put into a frame hive, the hive should be examined, and all the frames properly adjusted on their bearings: the bees may then be put in and the hive placed on its stand, which should be level, so that the hive will not lean to either side; but the hive may lean to the front or rear, as that will not cause the bees to build crooked. In four or five days after a swarm has been put into the hive it should be examined, and if there is then any inclination to build crooked, it can then be remedied by simply raising the frame and pushing the comb back to its place. In this way straight combs may be had in every hive. When it is found necessary to examine a stock and remove the frames, the bees should first be smoked a little, driving them down from the top to the centre of the hive. Then all bars that connect the combs should be cut away. There is no amount of honey in the bars, they being put there simply to strengthen the combs. When these are once removed, there is no longer any difficulty in removing the frames, which should at first be raised gently from their bearings and moved close together until sufficient room is given to remove a card of comb without crushing the bees. Too much should not be expected from the bees, but we should be more than satisfied if, with a little attention on our part, and the use of a frame hive, they may be caused to construct their combs in such a manner that they may be lifted out with so little difficulty. That the cards of comb may be separated, and removed from the hive at all, is a wonder, but by attending to the above hints every card from any number of hives may be removed, examined, and replaced at pleasure, giving perfect control over the bees and their combs.

Surplus Honey.—A subscriber sends the following queries:—

"Will you or some of your correspondents, experienced in the matter, please answer through the Canada Farmer the following questions:

"How long, after putting a young swarm of bees into a hive, should it be before I put in the surplus boxes; or should they be put in when the bees are?

"When is the best time to remove bees from one hive to another, taking care that they shall have time to gather honey sufficient for their winter's use?"

Ans.—The surplus boxes may be put in a hive three or four days after the swarm has been put in; but never immediately after the transfer unless there are already combs in the body of the hive, in which case they may be put in at once.

Bees may be removed from one hive to another at any time after fruit blossoms appear, either before or after swarming. Generally the earlier it is done the better after the honey harvest commences.

Report on the Philadelphia Raspberry.

To the Directors of the Fruit Growers' Association of Ontario.

It is now four years that the writer has had this Raspberry in bearing, and has in that time grown it with most, if not all, of the leading sorts of Raspberries, and carefully compared it with them all as to vigor of growth, hardihood or ability to endure the cold of our winters and the heat of our summers, productiveness, size of berry, and flavor. After such a test and comparison there seems to be a propriety in giving the opinions and conclusions that have been formed with regard to this fruit to the public in the form of a report to the Fruit Growers' Association.

Among all the Raspberries generally known or cultivated, the common black Raspberry, or as it is sometimes called, the Black Cap, so universally to be found in neglected clearings and fence corners, is the most hardy sort we have, withstanding perfectly our coldest winters, and enduring the heat and drouth of our summers. But this berry, with all its good qualities, still lacks the size and juiciness of the Antwerp class, while the Antwerps, though yielding large and juicy berries, could not withstand the cold of our winters without protection, and suffered often very severely during the trying heat and drouth of our summers. A Raspberry that should combine the powers of endurance possessed by the Black Cap, and yield a fruit as large, juicy and high flavored as the Antwerp, was and is a great desideratum. The writer procured the Philadelphia under the assurance that it did combine these qualities in a good degree, and it is the purpose of this Report to show how far this variety may lay claim to such great excellence.

In flavor it is not equal to most of the Antwerp class. The Brinckle's Orange stands at the head of all the raspberries growing in these grounds for richness and delicacy of flavor, and Franconia, Hornet, Imperial and Naomi all take precedence, in the writer's estimation, of the Philadelphia in point of flavor; not that there is anything unpleasant in the latter variety, but it lacks the richness of the others.

It is much more pulpy and juicy than the Black Cap, and in this respect is a decided advance on that variety, yet not quite as juicy as the other varieties above mentioned.

It is also larger than the Black Cap, considerably larger, yet not equal in size to the Franconia, and much short of the great Hornet.

In productiveness it far exceeds any of the sorts mentioned in this report, and is in this respect far superior to any variety that has been cultivated here. Indeed the load of fruit is quite surprising, and were it not that the canes are more stout than most varieties produce, the burden of fruit would drag upon the ground. In abundance of fruit it is (as was stated by Mr. Arnold, of Paris, at the last meeting of the Association) among the raspberries what the Wilson is among strawberries, head and shoulders above its fellows.

The test of five winters leads the writer to believe that the Philadelphia is *perfectly hardy*, as hardy as our native Black Cap. It has not killed back at all in some winters, and in others only the extreme tips have suffered. The blossoms are not injured, but come out along the whole length of the cane, hence the very abundant crop it produces every year.

It also endures perfectly the heat and drouth of summer, growing luxuriantly and perfectly its fruit much better than the Franconia. Not that in such an extreme drouth as has prevailed in this vicinity for the past five weeks it perfects every berry, or shows no lack of moisture, or that in hard or nearly sterile soils it will not flag under such intense heat and continued drouth; but in the same row with the Franconia, in the same soil and receiving the same treatment, it suffers less from heat and drouth, and brings to perfection a heavier crop.

The habit of growth is unusually vigorous, stout, and upright, enabling the plant to sustain its enormous crop; the foliage is deep-colored and heavy, and thus far there has no disease or symptom of disease appeared.

The conclusion to which we are carried by these experiments and comparisons is, that in the Philadelphia we have a raspberry that leaves nothing to be desired in health of natural constitution, in hardihood to withstand the cold of winter or the heat of summer, nor in immense productiveness. On the other hand, it does not possess all that we could desire in flavor nor in size of fruit.

Here is opened a field that needs at once to be cultivated by the careful hybridizer. With a mother so hardy and productive as the Philadelphia, what may he not hope to attain by crossing with the Brinckle's Orange for flavor, or with the Hornet for size? He who will add to the perfect hardihood and abundant fruitfulness of the Philadelphia, the size of the Hornet and the flavor of Brinckle's Orange, should receive a gold medal from the Association, and the lasting gratitude of his countrymen.

Meanwhile we must not do without our raspberries, and until such a happy combination is achieved, we can do nothing better than recommend every one to give the Philadelphia a trial.

Your most obedient servant,
D. W. BEADLE.

St. Catharines, 22nd July, 1868.

Failure of Young Orchard Trees.

To the Editor of The Canada Farmer.:

Sir,—I have noticed recently considerable failure among young fruit trees (the apple in particular), of two, three and four years' growth. As I own quite a number of different varieties, and from fifty to two hundred and fifty of each kind, my experience may be interesting as showing which are the hardy, which the tender varieties. The Baldwin seems to suffer most with me, the greatest part of them being dead to the bottom of the stem, while in some few the tops are entire, and others have escaped with the loss of a few branches.

The Rhode Island Greening comes next. A few have passed the season with the loss of the tops, and others with loss of last year's growth, but the greater part are doing well. I have lost others from the bark splitting from the ground from six to nine inches up the stem. This occurred early in the fall, as I supposed from too rapid growth. I should like to know if there is any means of preventing this. I have observed it before in trees of the same age, but with less fatal effect. It generally happens about the second year after planting, when they have begun to grow well.

Other varieties have been affected, but not to such an extent as the Rhode Island Greening and Baldwins. I shall try and send you a correct list of the loss on the different varieties as soon as I can get time. Pears have been damaged by the frozen sap blight. I have over one hundred dwarfs and standards, from four to six years old. In many cases I had to cut within one foot of the ground in order to get sound wood, and to remove a good many branches off others. Plums seemed to promise well, but now some trees shows signs of giving out, the stem getting dead first; others losing half of the tops. Out of about fifty trees there are only about six healthy, and the plums on all of them are shrivelled on the branches and dropping off from the excessive heat and dry season, although the trees were early mulched.

There was a good show of blossom on all fruit trees, but what was formed is now dropping off. I have older planted apple trees of the same varieties as those above mentioned that have stood well. The complaints are general respecting the young orchards here. I should like to know if in other parts of the Dominion the young orchards have been similarly affected. I may mention that we have had one of the coldest winters on record; an early break up in spring, cold weather again setting in. The fall was late, and exceedingly fine.

I have this spring destroyed the gooseberry caterpillar by mixing two dippers full of soft soap and one of air-slacked lime in a pailful of water, and thoroughly drenching the bushes with it, the leaves and ground remaining white with the lime. The variety on which I operated was the Houghton.

J. M. L.

Owen Sound, July 20th, 1868.

Toronto Electoral Division Society's Show.

The Summer exhibition of the Toronto Electoral Division Society was held on Thursday, 16th ult., in the Horticultural Gardens. The grounds, as usual at this season of the year, presented their varied attractions of foliage and flowers. The exhibition of Horticultural products, was laid out in a spacious tent at the northern part of the grounds. We are sorry to confess that the display altogether very much disappointed us; and it is a cause of much regret that the praiseworthy efforts of the Society to produce a love of horticulture are not more generally seconded by the gardeners and amateurs of Toronto and the neighbourhood. But for the liberality and generous interest taken in the institution by a few gentlemen in the neighbourhood, the show would have been meagre indeed. As it was, it owed its principal attraction to some fine collections of stove and greenhouse plants contributed by Hon. D. L. Macpherson, C. S. Gzowski, Esq., Judge Morrison, F. C. Chisholm, Esq., and one or two others. The number of exhibitors was remarkably few, and the prizes were distributed among only nine or ten persons altogether. A horticultural show in such a city as Toronto ought certainly to be very differently supported. The scarcity of exhibitors does not, however, in the least detract from the merits of those who competed, and who enriched the collection with some very beautiful specimens.

The centre of the tent was occupied by a long table, on which were displayed a very fine collection of stove and greenhouse plants, among which were very beautiful fuchsias exhibited by F. C. Chisholm, Esq. The same gentleman showed also on this table some fine black Hamburgh and Chasselas de Fontainbleau grapes growing in pots, and well loaded with rich-looking clusters of fruit. Conspicuous in this collection were a number of foliage plants and ferns, native and foreign, shown by C. S. Gzowski, Esq. Judge Morrison and Hon. D. L. Macpherson had also a variety of beautiful greenhouse plants on this centre table. Ranged on each side, upon the ground, were some palms and fruit trees grown in tubs, the latter bearing well, and all looking remarkably healthy. These were chiefly furnished by Mr. Gzowski. The remaining flowers were displayed on a table along one side of the tent, the table on the opposite side being occupied, very sparely however, with specimens of garden vegetables.

Among the flowers we noticed specially a plant of Yucca Filamenta flowering very handsomely and profusely, shown by Mr. James Fleming; also a variety of cut flowers, some very fine, some good hand and table bouquets, and a few beautiful baskets of flowers.

There was a small display of fruits—among them some fine grapes shown by Mr. Chisholm; peaches and other greenhouse fruit grown by Hon. D. L. Macpherson and C. S. Gzowski, Esq. Mr. Leslie showed some good cherries of the following varieties—Cleveland Biggareau, Belle de Choisey, Guigne Noir, Lincante, Napoleon Biggareau, Elton and Black Eagle. The same gentleman showed a few strawberries of the Agriculturist and Jucunda varieties, but these were past their prime. There were also, notwithstanding the dry season, a few plates of large raspberries, and none finer than those of Mr. Edwards, the Secretary. Judge Morrison and Hon. D. L. Macpherson showed some very fine currants.

Of the display of vegetables we cannot say much. We only trust that the exhibition in this department was no indication of the general produce throughout the country.

The judges were Messrs. Charles Weston, David Murray and Edwin Townsend, all of Hamilton.

Correspondence

Alsike Clover.

To the Editor of The Canada Farmer:

Sir,—It has been said by some that the Alsike Clover would not do well in Canada, that after the first year it would die out and fail to produce an abundant crop. That such is not the case, however, the sample I now send you will fully prove. It was grown by my brother, H. M. Thomas, of Brooklin, Ontario, and was taken from the same field that last year produced eight bushels of seed to the acre, this being the third year's growth. The whole field is a swamp of clover, and a perfect wave of flowers. It has been in full bloom for four weeks, and will continue for at least a week longer. It is abundant in honey, and a perfect cloud of bees visit it every day. For two weeks past the weather has been so dry that other flowers have secreted but little honey. Even white clover has failed to secrete its usual abundance, but my brother's bees have continued gathering large supplies from the Alsike Clover, and storing large quantities of surplus honey. I would urge the growing of this clover as being one of the best honey-producing plants, while at the same time it is more productive as a hay crop than red clover, and better calculated for winter feed for cattle. Eight or ten acres will be found sufficient pasturage for forty or fifty stocks of bees, and will well repay the trouble of growing it. H. M. Thomas will again have plenty of the pure seed for sale, which will be advertised in proper time.

J. H. THOMAS.

Brooklin, July.

Note by Ed. C. F.—The sample of Alsike Clover accompanying the above communication, exhibits certainly a most luxuriant growth; some of the stalks even now, though somewhat shrank, measure nearly five feet in length, and the average of the bundle is four feet nine or ten inches; which, especially considering the recent dry weather, is sufficient evidence that this plant is at home in the locality. Mr. Thomas's continued success in the cultivation of this crop, and the favorable account which others also give in reference to their own experience with it, should induce Canadian farmers generally to give it a trial.

Fine Sample of Wheat.

We have received from Mr. Samuel Berriman, of Stamford, a splendid-looking sample of Soule's Wheat, the heads being fully six inches long, and the stalks six feet. The date of the letter which accompanies the specimen is July 7th, and from the shrank condition of the grain we judge it was gathered very green. We cannot therefore say how the yield would prove when ripe, but subjoin Mr. Berriman's account, though we fear he will be greatly disappointed. "The sample," he says, "was grown in a light sandy soil, on the highest point of the mountain here, and distant about three miles from Niagara Falls and the Suspension Bridge. The subsoil is gravel, over one hundred feet deep. The yield cannot fall short of forty bushels to the acre.

"I have grown this description of wheat for sixteen years, regardless of midge, and with one solitary exception have done better than with any of the rough wheats, such as Midge-proof and Mediterranean.

"One acre of White Wheat is worth nearly two acres of red—in this way, supposing two acres in one field, the condition being the same in every respect, the one red, and the other white, both apparently equally good, if the red yield twenty bushels, the white will yield thirty. Now as to the price: if the red be worth $1 30 the white will bring $1 75. The straw also from the white is worth more than the red."

Bent Grass.

To the Editor of The Canada Farmer:

Sir,—I send you herewith a living specimen of a grass that grows somewhat abundantly in this city. It is the *Agrostis Alba* or *stolonifera* of botanists, and is known in common parlance as white bent-grass, or florin grass.

Unlike its congener, *Agrostis vulgaris* (red-top), it is not suitable for a hay crop, but it is one of the most valuable of known grasses for pasture, on heavy clay soils, or clay loams in moist situations, and when cultivated in such will surely double their productiveness. It will also prove very valuable to the landscape gardener in this country, for lawns and parks; making, when cut short and well trimmed, a thick green carpet with a soft nap.

As grass may be considered the basis of the farmer's wealth, I have sent you this specimen that some of your agricultural visitors may see it, and may possibly send other specimens to the exhibition at Hamilton.

A. KIRKWOOD.

Toronto, 22nd July, 1868.

Sheep Ticks.—A correspondent writes:—"Have you used with success, and do you confidently recommend 'Miller's Tick Destroyer?' This spring we used tobacco water for our sheep; whether we used it too strong or not I do not know, but several of the lambs were found dead a few days after."

Note by Ed. C. F.—We have used and can recommend Mr. Miller's Tick Destroyer as an efficient remedy for sheep ticks. Tobacco requires to be used with the greatest caution. The writer adds a note respecting a weed which has been very prolific in his neighbourhood The name is not clearly written. If he will send a specimen we can most likely tell him something about it.

The Canada Farmer.

TORONTO, CANADA, AUGUST 1, 1868.

The Season.

In our last editorial on the weather and crops (penned July 8), we chronicled "recent heat and drought." Since then, these inflictions have continued with augmented intensity, so that at this writing (July 28), every green thing is well nigh dried up. It seems hardly credible that so great a change can have taken place in so short a time. Yet so it is, adding another to our many lessons concerning the mutability of earthly things, and the uncertainties that beset the farmer's calling. Spring grain and root crops have suffered very severely, but it is matter for congratulation that the hay and fall wheat escaped, being too early to be injured by the heat and drought. It remains to be seen how far the remainder of the season may repair damages, but at present all nature has a scathed appearance which tells but too plainly of the fiery ordeal through which it has passed. Nothing shows the severity of that ordeal more convincingly than the state of recently transplanted trees. The early part of the season was a most favourable one for tree planting, and there were scarce any failures. Now, however, it is widely different. There has been great mortality in new plantations, nor are there wanting instances in which old established trees have succumbed. Liberal mulching has proved the only successful protection. Where this has been practised, life and growth have been maintained with very few exceptions. Heat seems to agree with insect life. The plague of flies has been worse than usual. Grasshoppers have been very numerous. The Cicadas have made merry all through the hottest days. Gardens and orchards have suffered greatly from insect pests. "The little busy bee," however, is an exception. It has found the heat unbearable, and has done little for days together, but fan itself, like a "nothing-to-do" lady.

Emigration Documents and Arrangements.

We have before us the "Return" to an address of date 7th May, 1868, by the Senate of the Dominion Parliament for all the correspondence which has taken place from the first of January last to the date of the address, between the Minister of Agriculture and the various emigration agents in all parts of the Dominion, as also in any ports of Europe, bearing upon the probable extent of immigration to be expected in 1868, and the arrangements made to meet and encourage said immigration; and the "first report of the standing committee on immigration and colonization."

A very considerable number of the letters given in the "Return" are of very little general interest, referring as they do principally to estimates of the probable expense of each agency during the current season, with instructions on the part of the Bureau, that the plan of forwarding destitute immigrants from Quebec to their destinations would henceforth be discontinued, or at the very most that any allowance of the kind would only be made in very exceptional cases. Against the strict enforcement of this regulation the emigration agents urge some very strong objections.

It is somewhat difficult to strike the just medium in such a matter, for it is very manifest that the system of "forwarding" is liable to great abuses; and, as a matter of fact, we believe has been greatly abused. Sometimes this has been the case from persons presuming upon this arrangement, and being sent with means barely sufficient to land them destitute in Quebec, as if afterwards the Canadian Government would take all care and all expense, and treat such immigrants, and care and provide for them, as if they were children. Often also we believe this kindness has been abused by parties who had means, feigning poverty, in order to secure conveyance at Canadian expense. At the same time, to make anything like a very stringent regulation stopping all this, might sometimes inflict great injury upon very deserving and very suitable parties, and deprive the country of some excellent settlers. It would be likely also to levy an extra tax upon the landing places, and possibly to divert a good deal of the immigration from the St. Lawrence altogether; for, as the agents urge, it is not to be forgotten that, after all, the capitation tax levied on each emigrant more than meets all the forwarding outlay, and even those who land without any intention of remaining in Canada, benefit the railways to a very considerable extent, and expend a good deal for provisions as well; so that it would be a matter of regret if anything should arise to stop the course even of that immigration by the St. Lawrence, from which our country derives the least benefit. We must acknowledge, at the same time, that we can see very little occasion for such excessive liberality as has been exhibited when parties have been "passed" through from Quebec to Chicago at Canadian expense. Let it be clearly understood that those who come to Canada must come prepared to work at the very earliest opportunity, and at whatever comes readiest to hand, and that all that can in reason be expected is that they be helped to the nearest place where their labour can be made available, after which they must look to themselves for providing the means to take them "further west." Thousands and tens of thousands have found Canada a "good land;" but those chiefly have benefited by it who have most fully believed in self-reliance and self-help. The Government can do a good deal, and it ought; but it is not to be expected that it should do everything.

From the correspondence we do not learn that anything has been done during the winter of this year to ascertain what may be the wants of the country, and where may be the most likely places for immigrants finding employment and a home. From all that is here published one cannot learn that anything like systematic enquiry has been set on foot, or that the local authorities in counties and townships have been at all communicated with.

Some requests were made by agents to be allowed to visit their districts and seek to ascertain by personal canvass how many immigrants might be likely to be absorbed in the various localities, and while these requests have not been absolutely refused they have been received in such a way, that nothing in the way indicated has been done. Even apart from personal visits, a great deal surely could be done by correspondence, if that were set about with something like heartiness and energy, but we are not told that this has ever been attempted. Even so early as the 6th of May, Mr. Donaldson, of Toronto, tells the Minister of Agriculture that the farmers around this city had been pretty well supplied with labourers, and suggests that a notice should be put into the journals inviting those at a distance to send in a statement of their wants; but we are not aware that such a notice has been to this day given in any paper in the western section, if indeed in any part of the Dominion. In short, with the exception of Miss Rye's female emigrants, which was not a Government undertaking at all, no attempt has been made to establish anything like a labour exchange, or to bring those who wish to hire and those who wish to be hired into contact and communication with each other.

In the Report of the Standing Committee, some rather interesting facts are given. The relation of the Dominion Government to the whole business of immigration is somewhat ill-defined and anomalous, inasmuch as the whole disposal of lands, minerals, &c., in each of the Provinces is entirely at the disposal of the local authorities. The first thing, accordingly, which the committee did was to issue a circular to the heads of the various Provincial Governments, asking their opinion on the point. To this circular, the answers of the Attorneys-General of Ontario and Nova Scotia are given, the latter, by the way, a production whose main object appears to be a display of the writer's dislike to confederation.

We are then informed of the Sanitary Arrangements for the reception of immigrants at Quebec, St. John, New Brunswick, and Halifax. The Quarantine expenses at Quebec were in 1866, $21,346 07. In New Brunswick for the same year, $418 65. In Halifax the expense, which is not specified, has been met by a tonnage on vessels.

The Agencies at work in 1866 are next noticed. In that year the salaries paid to the local agents in the Province of Canada were as follows:—

Quebec	$6,319.72
Montreal	1,500.00
Ottawa	800.00
Kingston	800.00
Toronto Agent and Assistant	1,817.00
Hamilton	780.00
Total,	$12,016.72

The total expenditure in the Immigration Department for the year in the above mentioned province was as under:—

Quarantine Establishment	$18,146.07
Inspecting Physicians	3,200.00
General Expenditure	7,148.81
Emigration, indirect relief	14,180.36
Contingencies of Agencies, Rents, Printing, &c.	3,911.72
Salaries of Agents	12,016.72
Total,	$58,603.68

Foreign immigrants during the same period paid to railway and forwarding companies for their inland transit alone over $100,000, besides the outlay for provisions, &c.; while the amount of immigrant tax collected in Quebec and Montreal amounted to $26,857, or nearly one-half of all the official expenditure on immigration.

In New Brunswick, there was in 1866 only one immigration agent, at an expense of about $1,000. About 808 persons arrived during the year in that province, of whom about 450 became permanently resident.

In Nova Scotia there was also one immigration agent, at a salary of $800. The number who came into Nova Scotia in the year specified was 932, of whom most of those who were agricultural labourers remained. The vote for 1867 was $4,000.

In 1866, in Quebec and Ontario, 3,393 immigrants were assisted to their destinations, at an expenditure of $14,180 36. What has been done in this way in New Brunswick and Nova Scotia cannot be ascertained, or at least is not given. A large portion of the report is taken up with a description of the terms on which lands can be acquired in the different Provinces, either by free grant or by purchase.

The system inaugurated at the beginning of the year in Ontario is described, and, with certain differences in detail, those of the other Provinces. We are glad to learn that the plan of Free Grants in this Province, though far less liberal than it ought to have been, is likely to have considerable success. It is mentioned that the Assistant Commissioner of Crown Lands for Ontario has sometimes had as many as 300 applications in a single day. The conclusions at which the committee arrived, and the recommendations they suggest to Parliament, are given in the following extract. Mr. Dixon, the agent in England, it will be observed, is blamed for sending out persons quite unsuitable for the country, though the evidence in support of this is not very convincing. It is recommended that his agency be suppressed, and in short that the whole system be reorganized, as it very much needs to be.

"The system," says the Committee, "which has been in existence for furthering and aiding immigration to Canada, has not been productive of satisfactory results, neither is it, in the opinion of your Committee, adapted to be so under the law which has placed the public lands under the control of the Provincial Legislatures.

"In order to avoid a conflict of authority, and to secure the efficiency of any general immigration scheme, it is necessary that there should be an understanding, and, consequently, co-operative action between the General and Provincial Legislatures. In the meantime, and before any such concurrent action can be agreed upon, your committee recommend that such care and assistance be extended to emigrants arriving seaward as may be necessary.

"Your committee recommend a discontinuance of the agency at Wolverhampton, in England, and such a reduction of the staff at Quebec, Toronto, and other agencies, as can be made consistently with the recommendation in the preceding paragraph, with a view to the early reorganization of these agencies.

"As the success of the emigrant depends greatly upon his willingness and ability to adapt himself to the conditions to which alone success is to be expected, your committee suggest that great caution and circumspection should guide any public effort to induce persons to emigrate. While Canada offers health, prosperity; and freedom to the industrious labourer and mechanic, she cannot assume any responsibilities on behalf of persons whose occupations or habits have been unfavourable to self-reliance, or to the practical exercise of intelligent efforts.

"Your committee have received a number of letters containing suggestions on the subject of emigration, and offers, on the part of the writers, to place their services at the disposal of the Government, as writers or lecturers on the resources of Canada, in Europe. It is not incumbent upon your committee to express any opinion in reference to the suggestions themselves, or to the gentlemen by whom they are made; for, if the views to which your committee have given expression, in this report, are in accordance with those entertained by your Honourable House, it will be the obvious duty of the Government, in conjunction with the Provincial Governments, to adapt the agencies in Canada, and elsewhere, to existing circumstances.

"The prospective acquisition by Canada of the fertile lands in the valley of the Saskatchewan and its tributaries is, no doubt, interesting to thousands who purpose to migrate from the Parent Country to one of its dependencies. In the present state of the relations between the North-West Territory and Canada, no precise plan for its settlement can be recommended or even considered by your committee, but they submit that, without any unnecessary delay, as much of these lands as are fitted for agricultural purposes should be made accessible, through the British territory, and offered on such terms as will be attractive to a class of settlers who desire to enjoy the fruits of their industry under the security of British laws and institutions.

"Coincident with the construction of the Intercolonial Railway a large quantity of land hitherto inaccessible will be available for settlement. During its progress the labourer will earn the means of sustaining himself in the early stages of his settlement. The chief drawback to settlement hitherto has been the difficulty of obtaining employment at a convenient distance, and then of conveying produce to market over a long line of almost impassable road. On the line, and within the influence of the Intercolonial Railroad, these difficulties will not exist; therefore your committee urge upon the Government of the Dominion the necessity of co-operating with the Provincial Governments, through whose territory the road will pass, in the adoption of a well considered and liberal policy with regard to settlement.

"The Legislatures of Ontario, Quebec, and New Brunswick, respectively, have passed homestead exemption laws. The former has also devoted large tracts of land for the behoof of actual settlers, in free grants of one hundred acres each, with permission to purchase an additional one hundred acres at fifty cents an acre. Though these terms are not precisely similar to the Homestead Exemption and Free Grant system of the United States, they are presumed to be equally favourable. Your committee doubt not that the terms will be altered or modified, should it be found in the interest of settlement to do so. The new policy, so far, appears to be liberal and progressive, and may be held as justifying a claim for adjustment by persons in arrears to the Government, on account of purchased lands in the comparatively recent settlements, but which lands, for various reasons, are of little real value."

"The mode in which the mineral lands in the Domion are to be disposed of, and the obligations imposed by the Governments, with regard to the manner of working these lands, will very much affect the number of mining immigrants, as well as the flow of capital necessary for the developement of our mineral resources.

"The mode of disposing of these lands should be at once inviting and encouraging; therefore your committee desire to express the hope that the public policy in regard to them will be quite as liberal as that which appears to have succeeded in the United States. By the investment of capital in extracting the treasures of the mines, a consuming population necessarily follows, so that, besides giving value to that which has no value while hidden in the earth, a home market is opened for the produce and manufactures of the country."

Beet Root Sugar Making

The *Mark Lane Express* of June 15th, 1868, contains an exhaustive paper on the beet sugar question, occupying nearly six columns, and written by the "Old Norfolk Farmer," a well known and able contributor to that influential journal. We cull a few particulars, bearing chiefly on the practicability and profit of beet sugar-making in Britain.

It would appear that there are two kinds of sugar possessing different characteristics and requiring different processes in their manufacture. The first and best of these is extracted from the cane, the Silesian beet-root, and the maple. The manufacture of sugar from these plants is purely a *mechanical* process. The second kind, termed "*a factitious*" sugar, is obtained from the grape and other ripe fruits, and starch or farina. To procure it, chemical agents and processes are necessary. The beet, therefore, ranks among the highest and best of the sources whence sugar is obtained.

Actual experiment has demonstrated that beets grown in Britain yield as large a proportion of saccharine material as those grown on the continent of Europe. The report of an investigation undertaken by Sir Robert Kane, director of the Museum of Irish Industry, and presented by order of Her Majesty to both Houses of Parliament, is most conclusive on this point. No fewer than 118 specimens of Irish-grown beet roots, from various localities, were carefully analyzed, when it was found that the quantity or percentage of sugar they contained ranged from 3½ to 14½, the low average being from large, and the high from small roots. It was also found that condition and quality of soil have much to do with the proportion of saccharine, but on all soils, the small roots yielded a larger proportion than the large ones. Comparison of the Irish beet with the Belgian beet shows that the former is fully equal to the latter.

Notwithstanding this fact, it is well known that while on the continent of Europe beet-sugar-making is a large and increasing interest, the attempts made in Britain to establish this branch of industry have proved failures. So far as England is concerned, three manufactories have been started, but were unable to make the thing pay, owing to the very heavy differential duty levied upon indigenous sugar. In other words, protection ruined them. The West India influence in the British Parliament was fatal to home industry. An effort to set going a similar establishment in Ireland also failed, from what cause or causes we are not informed, but it is distinctly stated that it was in no respect owing to the soil or climate not being adapted to the cultivation of the root. The French Government adopted a different line of policy, and protected the beet-sugar industry while in its infancy, by levying a duty on imported sugar. After a time a small tax was imposed on beet-sugar, which was gradually increased until in 1848 an equalization of the duty was effected, and the home-made sugar put upon the same footing as the imported article. Still the manufacture of beet-sugar progressed, being found highly profitable, until at length the French Government imposed a differential duty of five francs per cwt. on beet-sugar above that paid by the tropical sugar. So far from this branch of industry being annihilated or even injured by the governmental policy just described, it has steadily prospered, so much so that the product has more than doubled, as the following statement will show:

PRODUCE OF BEET-SUGAR MANUFACTURE IN FRANCE.

Year.	Tons.
1847–8	51,716
1850	100,000
1864–5	147,000
1665–6	275,000 (a very fine season.)
1866–7	215,000
1867–8	210,000 to 215,000 expected.

It thus appears that the beet-sugar manufacture, when once fostered into strength, is quite competent to hold its own against the tropical article, and even beat it in the contest. This would seem quite natural when it is considered that cane juice does not yield more than 10 or 12 per cent. of saccharine, that this must be expressed, boiled down, and finished for market in a very short space of time, rendering harvest labour costly, and that then there is a long, expensive, risky voyage to be encountered before the market is reached. A loss of 15 per cent. on the sugar and 20 per cent. on the molasses by drainage during the voyage must be counted on, as also the occasional bursting of a hogshead of sugar from fermentation, in which case there is total loss, as the scattered contents only sweeten the bilge-water in the vessel's hold.

Not in France only, but in the Continental States, beet-root-sugar making has become an established and growing industry, as the following statement will show:

QUANTITY OF BEET-SUGAR MADE IN GERMANY.

	Tons.
1864–5	170,000
1865–6	185,000
1866–7	200,000
1867–8 estimated at	165,000
AUSTRIA.	
1864–5	85,000
1865–6	70,000
1866–7	90,000
1867–8	95,000

Even in Russia the business is gaining a foothold. So long ago as 1856–7 nearly 7000 tons were made in that country. Returns of a more recent date are not given, but the manufacture of beet-sugar is constantly increasing; new and extensive works are springing up in every part of the country; and nearly enough is now produced to supply the whole population. In these countries the cultivation of beets has not interfered with any other branch of husbandry. No fewer cattle and no less wheat are raised than formerly.—In fact, wherever this branch of industry has been introduced the agriculturists have become wealthy.

The authority we are quoting strongly maintains that no reason exists why this manufacture should not succeed as well in the United Kingdom as on the Continent. He contends that the question rests, in point of fact, wholly with the agriculturists, whether it would pay them—not as well as wheat, for it must not for a moment be supposed that the cultivation of the sugar-beet would supersede that of wheat—but whether selling the roots would pay them as well as consuming them on the farm, or as growing common mangolds or turnips for the purpose. This question is pretty fully discussed, and the conclusion arrived at that it is for the farmer's interest to raise beets for the sugar market; that it will pay him as well if not better than the present system of root-growing and stock-feeding; that instead of impoverishing, it will enrich the soil, while it affords a living profit and something beyond; and that by feeding the residuum of the roots *after* the juice has been extracted, he can, with the addition of a portion of artificial food, fatten more stock than he now does. The last consideration adduced appears to be one of much importance. Beet pulp is about 30 per cent. of the entire weight, so that nearly one-third of the beet crop is available for feeding purposes after the juice has been taken out of it, and all this, be it remembered, or very nearly all of it, is solid food, and contains a small percentage of saccharine, it being found impossible to extract it all. On the Continent the sale of the residue is a regular part of the business of the manufacturer, though in some of the large establishments it is consumed on the premises, animals being bought and kept for the purpose.

If the above reasonings and conclusions are correct, and we see no reason to dispute them, they appear to show that the manufacture of beet-sugar is quite practicable, and tolerably sure to be remunerative in Britain; and if in Britain, the question very naturally arises, why not in Canada? The beet flourishes well in this country, and we believe is by no means deficient in the saccharine property, though we are not aware how far this point has been settled by chemical analysis. Until the appearance of the paper under notice, we did not know to what causes the failure of beet-sugar making in England was to be attributed. If the chief cause has been the West India monopoly and repressive taxation, of course it puts the questions of practicability and profit in a new light. We should greatly like to see this matter brought to a practical test. Of course this would involve the hazarding of some private or public capital; but success would open a new and important line of business that could not fail to be of great benefit to the public, while failure would set at rest a much agitated question, which only actual experiment can decide.

Value of a Railroad to the Farmer.

In several parts of the Dominion of Canada, railroads are being projected, and the agricultural communities through which they pass are asked to tax themselves towards the construction of such railways. People in general are averse to being taxed. They shrink from it with instinctive dislike, and deem that line of policy wise which keeps taxation down to the minimum point. But it is possible to indulge a short-sighted and unprofitable economy. We are by no means in favour of reckless railway building, nor do we counsel every farmer to try and get an iron track close to his own door. But the advantages of near access to market and cheap transportation of grain are very great. They benefit the farmer's pocket more than those who have only given the subject a cursory consideration are apt to think. The following, from an American journal, puts the subject in a striking, and as we believe, correct and truthful light:—

It is proper to bear in mind that the figures here given present only one of the many advantages that railroads bring. To haul 40 bushels of corn 50 miles on waggon would cost at least $12 for team, driver and expenses. A railroad would transport it for $1 at most. Allowing an average of 40 bushels per acre, the crop would be worth $8 more per acre, or 8 per cent. on $100. As the relative advantage is about the same for other crops, it is clear that a railroad passing through a town would add $100 per acre to the value of the farms. A town 10 miles square contains 64,000 acres. An increase of $100 per acre is equal to $6,400,000, or enough to build 200 miles of railroad, even if it cost $32,000 per mile. But 200 miles of road would extend through 20 towns 10 miles square, and cost $10 per acre, if taxed upon the land. These figures are given merely as an illustration. If the farmers had taxed themselves to build all the railroads in the country, and given them away to any companies that would stock and run them, the present increased value of their lands would have well repaid all the outlay.

JOURNAL OF THE FARM.—In place of the *Culturist*, one of our American exchanges which has been discontinued, we now receive the *Journal of the Farm*, a paper published in Philadelphia by Baugh and Sons. Of course, as we should all expect, one of the objects of this journal is to advocate the claims of the superphosphate manufactured by the publishers; but there is besides a large amount of valuable information relating to the garden, the farm, and rural affairs generally, and a due portion of its pages is set apart for household and fireside reading.

DIEHL WHEAT.—We direct attention to the advertisement of Mr. Lewis Springer in the present issue. We have before us a sample of the wheat which he has for sale, and have pleasure in stating that it is of excellent quality, sound, plump, and even. We receive favourable reports of this variety of wheat in many localities, though some parties have expressed their disappointment in regard to its merits. Mr. Springer says he has now grown the Diehl wheat for three seasons, the first time, however, only in very small quantity, in order to raise the seed. Last season he raised forty-four bushels to the acre, all free from midge. This season he expects to thresh out not less than forty bushels to the acre; and the grain is still free from midge. The soil of his farm, in Barton, near Hamilton, is a sandy loam. We recommend farmers on similar land to make a trial of this promising variety. It should be sown during the first fortnight in September.

Agricultural Intelligence.

British Agricultural Gossip.

BEDFORDSHIRE SHOW—WOBURN ABBEY—MESSRS. HOWARD—AGRICULTURAL MACHINERY—MR. MECHI—WEATHER AND CROPS.

To the Editor of THE CANADA FARMER:

SIR,—During the last few weeks I have been over portions of the counties of Middlesex, Hertford, Bedford, Cambridge, Suffolk, and Essex, have attended several markets and shows, and have otherwise had much personal intercourse with different parties connected with the landed interest. I have been invariably met by all classes in a kind and courteous spirit, and the being known as a Canadian has more than once enabled me to visit museums and other places of public interest, when the strict application of their regulations would have shut me out. I tell the people that in becoming a Canadian I am not one whit the less an Englishman, and that while our people love and cherish their native or adopted home, they feel proud of the old country, and are fully sensible of the honour and advantages of a continued connection with it. The doctrine that it is the duty and interest of the mother country to transport her surplus labour and capital to her colonies, where it will fructify and increase the strength and wealth of the empire, is certainly not unacceptable to the rural population, and in Lancashire even I have met with several instances of its recognition. The truth is, only the merest fraction of the British people can be considered in any sense or degree anti-colonial; "ships, colonies and commerce" is old England's motto and guiding star yet, and will continue to be so while sound statesmanship continues in the future, as it has in the past, to guide the helm.

The limits of a letter will only admit of a few allusions to such matters that have come under my observation as may possess some degree of interest to your readers, and here I may just remark that the site chosen for the Bedfordshire Agricultural Show this year, was the most beautiful, and comfortable for the cattle, that I have yet seen on either side of the Atlantic. The fine old park of Luton was granted for the purpose, and both visitors and stock felt truly grateful for the cool shade of these gigantic and symmetrical trees, such as form the characteristic beauty of English park scenery, during one of the hottest days I ever experienced. The show itself offered but few occasions for comment. I felt rather disappointed in its extent; many of our local shows in Canada exceed it in that respect. The quality, however, was generally very good, yielding therefore a *high average*, which I find to be now-a-days the ordinary condition of British exhibitions. I well remember the time when it was not so; a fact which should encourage Canadians to follow in this matter—and we may do so beneficially in others—the example of the parent State. The cattle were all either pure short-horns, or very largely mixed with strains of that blood. Mr. Charles Howard, of Beddenham, had some very fine specimens, and also Oxford Down sheep, a breed much cultivated and appreciated in this section. In most of the flocks bred for the butchers a mixture of Down blood of some variety, either with Leicesters or Lincolns, is quite apparent; but crosses are seldom bred from. The new Lincoln is decidedly making progress in many places, while in others the Leicester or Cotswold has a strong hold. The cart horses at the show I consider too heavy, at least for Canada, and even the lighter soils of England. But the modern Suffolk Punch, (not wholly unknown in Canada), seems to combine many excellencies as a draught horse—he has often good action, with decidedly a large amount of muscle compressed into a small compact compass. The dinners which inevitably form sequels to English shows, are not among the least of their attractions; good humour, and sometimes good speeches, containing useful and reliable information as the results of experience, characterize the proceedings. I must not omit to mention that in connection with Luton Park, a farm of a thousand acres, is the most complete and extensive farmery, probably, in the world. I have neither time nor space to enter on a full description of it here, but having got full particulars and a ground plan of the whole, I hope on my return to prepare a paper on the subject. The changes introduced of late years into agricultural architecture are certainly no less striking than those belonging strictly to the art of culture.

I had the pleasure of spending a day or two with my old highly esteemed friend, Mr. Thomas Bennott, land steward of the Duke of Bedford, Woburn Abbey. I wish I could give your readers an idea of the management of this princely domain. Park, (3000 acres within a high wall,) gardens, conservatories, with a mansion reaching back into remote antiquity, all on a magnificent scale, with numerous and extensive farms, villages, and churches, comprising the elements of a happy, orderly and well-to-do moral community. Whatever objections may apply to some large estates on account of bad management, have certainly no relevancy to Woburn. The Dukes of Bedford have for centuries been honourably distinguished, not only for sound statesmanship, but for an intelligent and munificent encouragement to agriculture and horticulture in all their branches; and some of the most happy and instructive gatherings to promote these objects have been held at this distinguished place. For many years past a thorough system of draining has been progressively carried out on this estate; a large number of improved farmeries and cottages erected, and every encouragement given to the improvement of agriculture, including both the farmer, mechanic and labourer. The old herd of Hereford cattle is still kept up in the park, and this breed continues to occupy a high position as beef cattle.

I have also had the gratification of inspecting the agricultural works of Messrs. James and Frederick Howard, of Bedford, and of the Messrs. Ransome and Simes, of Ipswich. These are the most extensive and complete of any, perhaps, in the world, and having jotted down many particulars, I propose, when I return, to give your readers a pretty full account of them. It is workshops like these that impress the conviction on the mind, not to be doubted or misunderstood, that agriculture is indeed rapidly becoming a science, and can no longer be looked down upon as a mere empirical art. The Messrs. Howard have a farm of some 600 acres near their works, and certainly their wheat, after steam culture, looked much more luxuriant than that of their neighbours after the ordinary manner. The fact is, both chemical and mechanical science are largely contributing their valuable aid to British agriculture, which owes probably as much of its modern improvements to the latter as to the former. I had time only for a mere glance at the farm of Mr. Charles Howard, a brother of the manufacturers, but that glance was sufficient to convince me that he occupies a high position among his countrymen. His extensive herd of Shorthorns contains some animals not to be excelled anywhere, and as to his Oxford Downs, they have already more than a British reputation. Mr. Chas. Howard is regarded as one of the most intelligent and successful English breeders.

On my return to London, through Essex, I spent a very pleasant day with Mr. Mechi at Tiptree Hall, near Kelvedon. It was twenty-four years since I visited this wide-famed farm, soon after Mr. Mechi had commenced his improvements. What a change did I witness! literally a "wilderness made to blossom as the rose." Here skill and capital have converted a formerly barren heath into a highly productive farm. It has been the work of enlightened perseverance, and the application of capital to a degree which many sober-minded people regarded, if not as reckless, still decidedly unprofitable. Mr. Mechi shows by his accounts that it has been far otherwise, and that he has reaped, at least, a fair profit. I can not now go into details, which I shall be happy to do at some future opportunity. I found Mr. Mechi as frank and generous as ever, although near a quarter of a century has elapsed since I last saw him; and he has suffered heavy losses during the recent commercial panic. I looked over seventy-five acres of wheat, drilled with one bushel of seed per acre, with a prospect of more than fifty-five bushels. A portion was dibbled with a peck per acre, and the crop, though a few days later in ripeness, will probably prove as large as the former; a fact clearly showing that superior cultivation requires less seed.

The agricultural prospects here are not very bright. The weather continues extremely hot and dry. Hay not half a crop, and spring grain generally must be very deficient. Swedes will be an entire failure, and mangels in some places nearly as bad. Keep for stock is very deficient, and should the drought continue for a few weeks longer (and there are no signs of a change at present) the consequences will be disastrous, for in many places there will be neither food nor water for sheep and cattle. Fortunately there is a considerable amount of old hay left throughout the country. Wheat is decidedly the best crop, and in the best, moist soils, will be heavy, but the yield generally will be affected from want of rain. Hops promise an abundant crop, but they have suffered of late from the same cause. The harvest will be unprecedentedly early; peas, barley and oats, on the forward soils, are already cut. It is said that so intense a drought has not been experienced in England and portions of the continent since 1818. I hear that in Canada the copious rains of May and part of June have been succeeded by warm sunshine, so that abundant crops may be reasonably anticipated; a result most devoutly to be desired. I am off to the show of the Royal at Leicester in the morning, and will send you some account of it the earliest opportunity.

GEO. BUCKLAND.

Hedge-Plant Growers' Convention

A convention of hedge-plant growers was held at Bloomington, Ill., June 25, 1868, for the purpose of organizing an association, and in various ways advancing the interests of their business. A Constitution and set of By-Laws were adopted, to the effect that the organization be called the "North-Western Hedge-Plant Growers' Association;" its officers to be a President, not less than five Vice-Presidents (who shall be *ex officio* Corresponding Secretaries), a Secretary and Treasurer, all to be elected annually. Any person actually engaged in growing hedge-plants may become a member for one year on payment to the Treasurer of $1 admission fee.

Capt. W. H. Mann, of Gilman, Illinois, was unanimously elected President, and on taking the Chair said he thanked the Association for this honor; that the fact that the hedge-growing interest of the North-west now involved millions of capital showed the necessity for this organization, and he bespoke for it a future of usefulness, both to the growers of plants and to the farmers who must depend upon them for fencing material. He had been over twenty years a hedge-plant grower, and he saw men now making mistakes that caused him serious losses ten or fifteen years ago. The discussions of this Association would prevent such errors by its members hereafter.

The following Vice-Presidents were then chosen: G. N. Parker, Kankakee, Illinois; S. W. Lamson, State Centre, Iowa; F. Safford, Marengo, Illinois; D. W. Norris, Paxton, Illinois; M. Neal, Bloomington, Illinois.

H. N. Pearse, of Bloomington, was elected Secretary and Treasurer.

Official Reports of the Condition of the Crops in the United States.

THE following is from the Department of Agriculture:—Wheat—an increase of the average is observed, in a greater or less degree, in nearly every State. The Eastern States show no increase of fall sowing, except four per cent. in Vermont, but the enlarged area of spring crops, which are the main home reliance for bread supplies, is very marked in Maine and Vermont; the former showing an advance of twenty-six per cent., the latter of sixteen per cent. New York indicates five per cent. increase in the fall average, with no change in spring wheat. In Delaware a reduction of seven per cent. appears, while an increase of nine per cent. is shown in Maryland, eleven in Virginia, seventeen in North Carolina and South Carolina, eleven in Georgia, ten in Alabama, fifty-three in Mississippi, thirty-one in Arkansas, forty in Tennessee, and thirty in West Virginia. The increased acreage in the West, where the great bulk of the wheat crop of the country is grown, is of peculiar significance of the State in which winter wheat is mostly cultivated. Ohio presents an increase of five per cent. of that variety; Indiana, ten per cent.; and Michigan seventeen per cent. In portions of these States an unusual effort has been made to enlarge the area by spring sowing, showing respectively eleven, fourteen, and six per cent. increase in the States, which rely mainly upon spring-sown crops. Illinois indicates an increase in that variety of twelve per cent.; Wisconsin, four per cent.; Minnesota, twenty-three per cent.; Iowa, twelve per cent.

An analysis of these averages will show a general average of about eleven per cent. increase in the fall sowing, and twenty-eight per cent. in the breadth of spring wheat, altogether an increase of eighteen to twenty per cent. in the aggregate number of acres in wheat. The reports of the condition for June are generally very favourable. A promise of the best crop ever known is held out by local correspondents in many places, particularly west of the Mississippi. Winter grain on new land is looking very well; but there is a large proportion of wheat sown on old, worn-out land, poorly managed, and a very light crop will be the result. Barley—Kentucky, Missouri, and Minnesota have given increased attention to barley, but most of the other States are either slightly below the average or barely up to it. The fall sowing especially was deficient in most of the Western States, but the deficiency was generally made up by extra exertions in preparing for a spring crop. Oats—An increased area in oats, averaging seven per cent. for the entire country, is reported. Clover—It is worthy of note that every State in the Union reports an increased attention to the clover crop, with the single reduction of two per cent. in New Hampshire, and the prospect for a good crop is almost universal, Kentucky only being marked a trifle below the average. Pastures—Delaware and Wisconsin are the only States failing to give increased averages. Fruits—The appearance of apple blossoms was unusually late on the Atlantic coast, opening very fully; at last they were injured in many places by storms and unpropitious weather. In the central portion of the West, the bloom of the orchards was not generally abundant. It was small on the Atlantic coast between New York and Georgia. With the single exception of apples west of the Mississippi it was large, and in some localities excessive.

Royal Agricultural Society's Show.—This world-renowned agricultural gathering was held this year in Leicester, and was one of the largest exhibitions ever collected together in England. The show and trial of implements was one of its most prominent features. This is the twenty-ninth show of the Society. It commenced on July the 8th, and was not closed up to the date of our latest British exchanges, July 15th. In the expectation of receiving a report of this interesting meeting from our esteemed correspondent Professor Buckland, now in England, we defer for the present any further notice of the occasion.

☞The hay crop in England is mostly harvested. The crop turns out to be much lighter than was at one time anticipated, in consequence of the exceedingly dry weather during the last few weeks. It was expected that reaping would commence some time about the middle of July. Alderman Mechi, the celebrated farmer and owner of the model farm, has written a letter to the London *Times*, in which he prophecies that the yield of wheat will be exceedingly large, more especially on heavy clay lands, which the late dry, warm weather has exactly suited. Another writer remarks that the hottest, driest seasons have always been noted for heavy crops in England. The summers of 1826 and 1854 were exceedingly warm, and the crops of those years were the finest known for fifty years past.

Agricultural Meeting.—The Orillia *Expositor* says:—A meeting of the Directors of the Muskoka Union of Townships Agricultural Society was held at Bracebridge, on the 16th inst., when the Secretary read a draft of rules, which were adopted. Settlers in Muskoka would do well to bear in mind that for this year provision has been made in the rules entitling those who may join before the 1st of September to all the benefits of membership. This liberality should be rewarded by a large accession to the list of members. The meeting adjourned to meet at Gravenhurst, at ten o'clock, on Thursday, the 30th July, for the purpose of enrolling members, and to afford an opportunity of explaining the objects of the Society.

Oxford Wool.—The Woodstock *Sentinel* says:—The wool market has closed for the season. The quantity of wool purchased this season in Woodstock falls short of that of last year, by the several purchasers. This year, Thomas Oliver, Esq., was the principal buyer, and has shipped a quantity equal to the one-half of all that was purchased. Last year Mr. Oliver shipped 23,000 lbs—this year he has shipped 37,000, that is 14,000 lbs in excess of his shipment last year. The average price of Mr. Oliver's shipment is 25¼ cents per pound.

Traction Engine.—The Traction Engine lately imported by Mr. Sutherland Taylor, having been successfully tested as to its capacity for drawing heavy loads on our ordinary roads, and surmounting the difficulties of pretty steep inclines, has been sold by the importer to an enterprising Canadian firm. The purchasers are Messrs. John Bruce and James Waterson, of Walkerton. They intend to place the engine on the route between Walkerton and Guelph, to accommodate the growing and already extensive trade of that locality. Their enterprise in an entirely new branch of the carrying trade should ensure for them every encouragement.

Gambling in Cereals.—The recent gambling operations in wheat in Chicago and Milwaukee, in which merchants of the latter city, by their superior sentences, came out ahead of the Chicago schemers, making a considerable margin by the operations, drew the following from the recent Convention of North-Western millers at Chicago:—

"*Resolved*, That we deprecate all gambling operations in wheat and flour, all corners and efforts at cornering, as unjust to the manufacturer by disturbing the value of the commodity, and as oppressive to the labouring man, who is compelled to bear the burden of the high prices of the staff of life, and that such conspiracies against the interest of the poor and labouring man are deserving of universal reprimand."

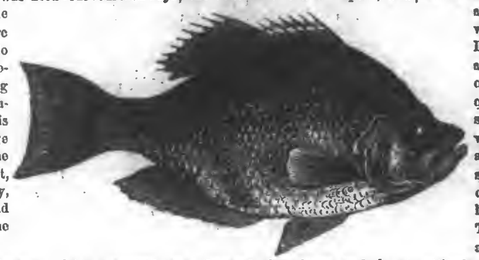
Canadian Natural History.

Rock Bass.

(*Centrarchus Æneus.*)

Having already noticed and illustrated the larger species of the [Perch family, we have selected for our present illustration a very common and much smaller species, well known to all the frequenters of our lakes, namely, the Rock Bass. We are indebted to that excellent authority "Frank Forester's Fish and Fishing" for the following description.

The general colour of this fish is a dark coppery bronze above, with green reflections, the head above dark green, gill covers metallic green, with a dark spot on the posterior margin of the operculum. The sides golden copper, with several rows of oblong dark spots below the lateral line. The fins bluish green. The body is compressed, short, and broad. The dorsal outline gibbous; the lateral line following the curve of the back. Head large, with a concave outline. Gill-covers scaly; the operculum with rudiments of a double angle on the posterior margin; lower jaw somewhat the longest. Teeth small, conical, recurved, on the maxillaries, intermaxillaries, vomer, palatines, and pharyngeals. The dorsal fin has eleven spinous, and twelve soft rays; the pectoral fourteen rays; the ventrals one weak spine, and



five branched rays; the anal, six spinous and eleven soft rays; the caudal, with rounded tips, has seventeen rays.

The Rock Bass is a good flavoured fish, and affords excellent sport to the angler. In some places it is so abundant, however, as hardly to afford sport in its capture. It is taken off the wharfs and docks on all the lake waters from Kingston to Lake Superior. It rarely exceeds a pound in weight.

There is another species of Perch famous on Lake Ontario, and often confounded with the Black Bass, but most probably distinct, namely, the Oswego Bass. Of this fish a writer quoted in the work to which we have already alluded, says:—"The Oswego and Black Bass bear so strong a resemblance to each other, that not one fisherman in ten knows them apart. In form, colour, weight, and habits, the two are almost identical; and yet their differences, though minute, are striking and essential. An Oswego Bass, when placed by a Black Bass of the same size, is readily distinguished by his more forked tail, his greater thickness of shoulder, his coarser scales, and, above all, by his mouth, which, when open, is nearly twice as large as that of the Black Bass. In Lake Ontario, the Oswego Bass is abundant, and the Black Bass comparatively rare. In Lake Erie the Black Bass greatly predominates; and it may be doubted whether the Oswegonian—like certain citizens of the Ontario shore—is not an interloper in our waters, who has found his way to us from below, through some canal. However this may be, he is certainly right welcome."

The small species, the subject of the accompanying illustration, needs no particular skill to capture, and scarcely gives sufficient sport for the experienced angler, but the larger kinds furnish excellent angling. The Black Bass, it is said, will seldom take the hook in the rivers until June. He is always good eating but is in best condition in August. An enthusiastic disciple of Isaac Walton gives the following account of his experience with this fish in Lake St George:

"This is a game fish, affording the angler the very highest enjoyment. These fish are taken in various ways. When collected on their feeding grounds, in August and the succeeding fall months, they are sometimes taken in considerable number. The usual mode of angling for them at this time, is either with or without a float and with live bait—a small fish taken for the purpose, along the lake shores or in brooks. They are exceedingly strong and active—qualities which delight the angler. When first hooked, they run very wild, and almost invariably rise to the surface, and leap one, two, and even three feet in the air, shaking the head violently, evidently with a view to dislodge the fatal hook. Frequently, while making their runs, they will suddenly turn and come with all their power directly towards their enemy, and by thus slacking the line, will succeed in shaking the hook loose: this often happens with inexperienced fishermen, but more rarely with the angler who holds a good reel and winds rapidly. The most beautiful mode of angling for them known, is trolling, either with live bait or an artificial fly of large size and gay appearance. The writer has succeeded remarkably well with a fly made on a large-sized Limerick hook, such as are used for Striped Bass when fishing with crab bait. The fly is made as follows: Body of a peacock feather, wings of bright scarlet kerseymere and white pigeon feathers; or, the feather stripped from a white goose-quill, and wound round like the hackle, and surmounted with thin strips of scarlet for wings. For trolling pleasantly and comfortably, the angler should provide a moveable seat, which he can place across the gunwale of his boat, in order that he may sit with his back to the oarsman, and facing the stern. Thus he will have full command of his rod and line, and not be sitting in the cramping attitude which the lowness of the seats would cause. He should reel off fifty to sixty, or even one hundred or more feet of line, and in going over shallow reefs of seven or eight feet depth, two hundred feet, as the fish feeding on the reefs usually dart aside as the boat passes, and do not return immediately to their harboring spot, which is one reason why those who do not use the reel are not as successful as those who employ it. After a few moments they glide back to their favorite spot, and as the fly comes along, dart at and seize it. A strong tug is felt by the angler, who has only to draw gently, and his prey is fastened. The oaraman rests on his oars, to give the angler full command of his line. The noble fish, after one or two runs to right and left, suddenly rises and makes his splendid leap, and plunging, again seeks the bottom, again rises, and then tries his last experiment of dashing right towards the boat. He struggles long and vigorously, but his strength is at last exhausted, and you trail your unresisting captive to the landing net."

The same fish is taken in great numbers, and of unrivalled excellence, in the St. Lawrence, among the Thousand Islands.

Acclimation of Birds.—We translate the following from the *Courier du Canada*, published in Quebec:—"M. W. Rhodes, of this city, has recently received from Europe twenty-five couples of insectivorous birds, known in Ireland under the name of common sparrows, which are destined to be acclimated in this country. All that M. Rhodes demands for his little *protégés* is that they shall have the same protection as that provided by law for the various species of insectivorous birds which are indigenous to the country."

Stuffing Birds.

To the Editor of The Canada Farmer:

Sir,—For the information of those of your readers who may wish further instruction in the art of Taxidermy, I will now proceed to give directions for stuffing birds; and will take just as an example the Pigeon, for skinning which instructions were given in a former article. Let us suppose the bird just skinned with the skull attached. I will treat on mounting dried skins some other time. The first thing is to replace the skull after it has been well anointed with the arsenical soap and inside with solution of corrosive sublimate. The bird is now laid on a table with the head towards the left hand, and the legs and wings adjusted to their proper situation. A pound weight is laid on the tail, while the feathers of the margins of the opening are raised by the fore-finger and thumb of the left hand to prevent their being soiled. The inside of the neck is now coated with arsenical soap; flax, tow, or cotton is then stuffed into it, but not too tightly. The back and rump are next anointed, and the body should be partly stuffed with tow, putting in about one-third the quantity that would be required to fill up the whole carcass. The simplest way to form the carcass is to take a cork from a wine bottle, say 1½ inch long by one inch in diameter; put a straight piece of annealed wire the whole length of the bird, from head to tail, then bend a piece of wire the shape of the letter V, and push it through the cork from the end which you intend for the head, leaving the projecting ends long enough to reach beyond the longest toes. You may now wind the cork with tow, or cotton, forming an artificial carcass. Then you put the wire through the neck, running through the skull; then push the wires through the legs, that is between the skin and the bone on the back side, and through the soles of the feet. Lastly, thrust the tail-bearer, or wire to support the tail, into its place; then finish stuffing. The skin is now brought together and sewed up, taking the greatest care to separate the feathers at every stitch. The orbits of the eyes are next finished, by inserting a little chopped cotton, attention being paid to round the eyelids properly. The glass eyes are now inserted, taking care to insert them properly under the eyelids. But before fixing the eyes, a little calcareous cement must be used to prevent them from coming out. The stuffing of the bird being now finished, the next thing is to place it on a piece of plank, by boring two holes for the reception of the wires which have been allowed to protrude from the soles of the feet for fixing the bird. These, of course, are pierced in such a situation as is necessary for the attitude or position of the legs. The wires are put through these holes and twisted so as to secure the bird in its position. The attitude of the bird will of course depend upon the fancy and taste of the operator, and ought to be in conformity with the habits of the bird in a living state. The leg wires are to be bent something like the letter Z, as in the skeleton. Give the neck and head its proper shape; smooth all the feathers down, and set it in some airy place to dry, and then your work is done.

The following is the composition of the

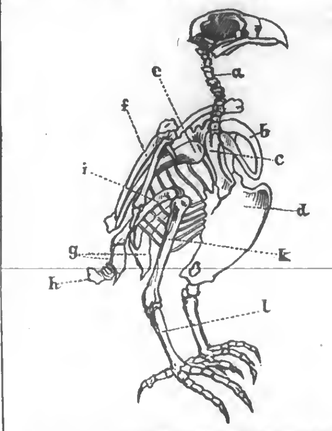
ARSENICAL SOAP.

Arsenic in powder	2 pounds.
Camphor	5 ounces.
White Soap	2 pounds.
Salt of Tartar	12 ounces.
Powdered Lime	4 ounces.

The soap must be cut in small and very thin slices, put into a crucible with a small quantity of water, and held over a gentle fire, and frequently stirred with a wooden stick or spatula. When it is properly melted, the powdered lime and salt of tartar must be added and thoroughly mixed. It must now be taken off the fire, the arsenic added gently and stirred. The camphor must then be added and stirred; but it must first be reduced to a powder by beating it in a mortar, with the addition of a little spirits of wine. This must be added while off the fire. It may then be held over the fire to assist in making the ingredients incorporate properly, but must not be much heated, as the camphor will very rapidly escape. It may now be poured into glazed earthen pots, and allowed to cool, after which a piece of paper should

be placed over the top; and over this some sheep leather; then set aside for use. The composition is about the thickness of flour paste. When it is necessary to use the soap put as much as will answer the purpose into a preserve pot, and an equal proportion of water. This is applied to the skin or feathers with a bristle brush.

N. B.—It should be kept as close as possible, and used with caution, as it is a deadly poison.



As a guide to the correct anatomy of a bird, which should always be borne in mind in forming the carcass and fixing the attitude, the accompanying outline of the skeleton of a falcon is given, with lettered references. *a, cervical vertebræ; b, clavicle; c, coracoid* bone—an appendage to the clavicle or collar-bone peculiar to birds; *d, sternum* or breast bone; *e, humerus; f, ulna; g,* portions of the *Ilium* or hip bones; *h, sacrum,* and *os coxygis; i, femur,* or thigh-bone; *k, tibia; l, tarsus.*

A. B. B.

Entomology.

Entomological Society of Canada.

The Annual General Meeting of this Society was held, by invitation of the London Branch, at their rooms in the City Hall, London, Ont., on the 7th of July; the President, Prof. Croft, of Toronto, occupying the chair. The following members were present: Messrs. Croft, Saugster, Clementi, Bethune, and Osler, from the Parent Society; Messrs. Saunders, Reed, Barker, Griffiths, Puddicombe, Denton, Chapman, Waterman and Simpson, of the London Branch.

The minutes of the last meeting, the reports of the Quebec and Toronto Branches, and the Financial Report were read and adopted. After the reading of letters of apology from various members, and other communications, the meeting proceeded to the election of officers for the ensuing year, with the following result:

President—Prof. Croft, D.C.L., Toronto University.

Vice-Presidents—Johnson Pettit, Esq., Grimsby; Wm. Saunders, Esq., London.

Ex officio Vice-Presidents—Rev. O. Brunet, President Quebec Branch; J. M. Denton, Esq., President London Branch.

Secretary-Treasurer—Rev. C. J. S. Bethune, M.A., Credit, Ont.

Curator—W. H. Ellis, Esq., M.A., Toronto.

Council—G. J. Bowles, Esq., Secretary Quebec Branch; E. Baynes Reed, Esq., Secretary London Branch; J. H. Sangster, Esq., M.D., Normal School, Toronto.

A number of eminent Entomologists in the United States were nominated for election at the next meeting as Honorary Members of the Society; the number of such members is limited by the Constitution to twenty-five. A discussion then took place respecting the publication by the Society of a small periodical to contain the transactions of the Society and serve as a medium of intercommunication among Entomologists in this country. It was finally unanimously resolved that a periodical, to be entitled the "Canadian Entomologist," should be issued by the Society, under the editorial management of the Secretary, the Rev. C. J. S. Bethune, and be distributed gratuitously to members of the Society, and at the rate of fifty cents per volume of twelve numbers to non-members.

After a couple of hours adjournment the meeting re-assembled at 8 o'clock p.m., and proceeded to the examination, comparison, and discussion of Longicorn Coleoptera (*Cerambycidæ*), or wood-borers. Large and interesting collections of this family of insects were exhibited by Messrs. Saunders, Croft, Bethune, Reed, Sangster, and Clementi; among them were to be seen specimens of nearly all the 127 species enumerated in the Society's printed list, and also a few more species new to Canada, as well as some foreign specimens from the United States and Mexico. A few new species of Lepidoptera were also exhibited, while on the table were some powerful microscopes, and a number of handsome works on Entomology, including an unpublished volume of plates by Mr. Townsend Glover, all of which attracted a great deal of attention. Notwithstanding the intense heat, which the members almost vainly endeavoured to modify with ices and other cooling refreshments, a very pleasant and instructive evening was spent.

The following day, Wednesday, July 8th, was devoted to a very pleasant Entomological Field-day and Pic-Nic. The heat, though still great, was tempered by a most refreshing thunder storm during the previous night, and nature looked all green and fresh and bright. After a few miles drive into the country, the chosen spot was reached, and the members betook themselves to the woods, fields, and river side, in quest of their tiny game; two or three

hours were spent in the capture of various orders of insects, and a fair measure of success was attained by all, many rare and interesting specimens being taken. At mid-day all re-assembled under a shady grove of wild cherry-trees, and did full justice to an excellent lunch provided by our hospitable London friends. The rest of the afternoon was devoted to more captures, bathing, and hunting, while some, unwilling to encounter again the blazing heat of the sun, enjoyed a quiet pipe and chat under the shady trees. Before returning to London, photographs were taken by Mr. Griffiths of all the members in a group, with their nets and other apparatus, as a memento of this first gathering under the new constitution. In the evening the Society re-assembled at the house of Mr. Saunders, the Curator of the London Branch, and spent some pleasant hours in the examination of his large and varied collections, and the use of the microscope.

The next day, Thursday, a few of the members paid a visit to the strange natural ponds, a few miles south of London, and collected a number of rare and beautiful insects and plants. This closed a most agreeable reunion of the members of the Society, which will long be remembered by all who took part in it; the members from a distance all expressing themselves highly delighted with the unbounded hospitality and kindness of their London friends.

Knocking the Curculio.

It is becoming generally admitted that jarring down the curculio on sheets extended for the purpose, is on the whole the most effectual and certain of all remedies. There are other modes or auxiliaries which are useful, and which sometimes of themselves are sufficient to give good crops. Allowing a herd of swine, for example, to run among the trees, from the moment the punctured fruit begins to drop until it approaches maturity, these animals will eat every young larva, and generally save the crop the following year. The trouble, however, with most persons is, that they do not give it a complete trial. A single year's experiment obviously will not answer. It must be continued without intermission for an indefinite period. We knew a cultivator who had heavy crops of plums for seventeen years in succession—his swine for these seventeen years, without a season's interruption, being allowed the run of the yard.

But where the insects are abundant, no other method may answer but the immediate, direct and certain assault of jarring and pinching.

We published, two years ago, the result of a perfectly successful experiment on an orchard of seventy trees, which became heavily loaded throughout, although in previous years we had not had a peck of fruit when no care had been taken.

Although it is now some forty years since the late David Thomas first introduced this efficient mode, and proved at the time the inefficiency of mere shaking the trees, and the importance of a sudden sharp jar, we find all over the country that this difference is still generally unappreciated. It is common to cover the mallet or bar of wood with cloth and cotton batting in order to prevent the bruising of the bark. The soft taps thus given are quite inefficient to bring down all the insects. Let any one try the experiment with a tree fully infested; shake it first, and he may possibly get two or three curculios; jar it next with the soft cushion already described, and he may get two or three more, but strike the tree with the back of an axe, which will impart a sudden and sharp jar throughout all the branches, and not a Turk will retain his hold. To prevent the bruising of the bark by these sharp blows, we have formerly adopted the practice of sawing off a small limb, leaving a stub an inch long, against which the axe or hammer might be struck without injury to the tree. But we have recently discovered an easier, better and more efficient mode. It was introduced by our correspondent E. W. Herendeen of Macedon, and we have adopted it with entire success. It consists in driving an iron spike into each tree nearly up to the head, at such place as will most effectually jar the whole tree. A stroke on the head of this spike will be more sudden and more certain to dislodge the curculios, than anything else that has been tried. The size of these spikes may vary with the size of the tree. For those of medium growth, what is commonly known as a twenty-penny cut nail, will be about right—first breaking off about an inch of the point before driving. For larger trees heavier spikes will be necessary—boring a small hole just before driving. Railway spikes might be inserted, against the heads of which very efficient blows may be given. No injury to the tree can result from their insertion, as no uncovered wound is made.—*Country Gentleman.*

Leaf-rolling Caterpillar on the Apple.

To the Editor of The Canada Farmer:

Sir,—You invite farmers to communicate anything that may be of interest. I am but a tyro in the science of Agriculture, and am willing always to be an enquirer rather than a teacher.

An acquaintance of mine called my attention a few days since to an enemy of the apple tree, of which I had no knowledge previously—a member of the caterpillar tribe snugly ensconced within a leaf of the tree, which was curled about it. Have you noticed it? and what is its name and habits?

JOHN Le BOUTILLIER.

Note by Ed. C. F.—The insect referred to is the larva of a moth belonging to the tribe *Tortricina*, or leaf-rollers, so called from the habits of the caterpillars. Without seeing specimens we cannot, of course, tell to what species to refer that noticed by our correspondent on the apple; it may, however, be that named by Dr. Fitch the "Apple shoulder-striped Tortrix" (*Brachytænia Malana*).

Most observers of insects and their ways must have noticed the curious manner in which the edges of leaves are often rolled up by some small caterpillar, for the purpose of obtaining shelter and protection as well as food. Their mode of constructing this habitation is remarkable; first the little caterpillar fastens a number of silken threads from one side of the leaf to the other; then it draws these threads together till the opposite edge of the leaf is curled over, when it fastens it down with more threads; should it discover that the larger ribs of the leaf will not readily bend, it gnaws them partially through, and thus cleverly effects its object. In this way a cylindrical tube or cone is made, in which the tiny architect spends its life and undergoes its transformations. A large number of species of this tribe are found in this country; one—the larva of a very pretty moth (*Desmia Maculalis*)—infests the grape-vine, and is often so numerous as to defoliate the vines in some parts of the Western States; another is plentiful on the leaves of the Bass-wood; while others may be found on various trees and shrubs. They may easily be destroyed by crushing the curled leaf in the hands.

The Three-lined Potato Beetle.

(*Lema trilineata*, Oliv.)

The following letter was addressed to Prof. Buckland, of the Bureau of Agriculture and Arts, Ontario, but in consequence of his absence in Europe, it has been sent to us with the writer's consent:

Dear Sir,—Accompanying this you will receive two bottles, one containing the bug—a true one, I think—of the largest kind of Aphis; also the slugs, (in the other bottle) produced from their eggs. These I gathered in Moore this morning, where they are infesting and destroying the potatoes. The bug appears on the top of the leaf, lays the eggs at the axil of the upper leaves, near the flower, and the slug, a slimy one, appears under the leaf and devours all the vegetable matter therein. I have recommended to let the slug appear, and then, with a broom, brush the slugs off; a very light touch makes them fall, and they die as soon as they touch the ground. I thought you might like to hear of this new pest, and so send you specimens. I will inform you of the final effect on the crops. I remain,

Yours truly,
W. P. VIDAL.

Sarnia, July 9th, 1868.

The specimens sent with the letter represented two stages in the life of the "Three-lined Potato Beetle"—the slugs being the larvæ of the beetles. Last year we gave a description and figure of the insect (C. F. Aug. 15th, 1867, p. 252), to which we beg to refer our readers. This devourer of potato leaves we have long known and observed in different parts of the country, but it has seldom proved very destructive; this year, however, we expect to hear a different account of its work, as in many places it is more numerous than we ever saw it before. We shall be anxious to learn from Mr. Vidal how far its depredations will have affected the yield of potatoes in the Township of Moore. The remedies that have been employed with the greatest success are dusting the larvæ with lime, ashes or soot; and brushing them off into a vessel and destroying them with hot water. Children might be advantageously employed in this work with but little expense.

The Privet Sphinx Caterpillar.—Mr. Brown, of the Louisa Street School, Toronto, sent us the other day a specimen of this large caterpillar. It is about three inches long, of a delicate pale green colour, with a series of whitish oblique stripes along the sides, and a sharp horn-like tail on the last segment. We tried to feed it on privet, lilac and other leaves, but it refused to eat, and on the 19th July turned into a chestnut-colored chysalis, about two inches long, with a short, thick tongue-case pressed close to the body. Next year, if all goes well, it will turn into a large ash-colored moth whose wings expand about five inches. It is unusual for these caterpillars to turn into the pupa state so early; their general period for transformation is about the end of August or beginning of September.

The Household.

Washing Made Easy

Mankind, and more especially womankind, have long been agreed that whoever should banish, or even mitigate the horrors of washing-day, should be assigned a high place among the benefactors of the human species. The aspirants for this honour have been very numerous, and their efforts have been worthy of more success than they have achieved. A legion of washing machines have been invented and brought into the market, but no one among them has operated satisfactorily. Various chemical preparations for taking out dirt without the tedious and fatiguing process of hand-rubbing have been tried and found wanting in some one or other of the elements of efficiency. That rude kitchen utensil the wash-board is the only apology for an assistant that woman can press into her service when the soiled linen of the family, heaps upon heaps, demands purification. A sorry helper it is at the best!

There is reason to think that a truly valuable discovery has been made, whereby the toils and sorrows of washing-day may be very greatly lessened. "Clark's Excelsior Washing Composition," a recently patented preparation, and said to be free from the objections that lie against other compounds of the kind, is winning golden opinions in many quarters, and comes before the public with most respectable certificates as to its capabilities. The patentee, Rev. W. W. Clark, a highly respectable Wesleyan Minister, is well known to us, and is too honourable and upright a man to sell a recipe for mere purposes of money-making. He simply asks for his "composition" a fair trial, and offers, if it does not give full satisfaction, to refund the money (one dollar) charged for the secret of its preparation. It is warranted perfectly free from everything injurious to hands, clothes, or health. Clothes require no rubbing, except it be very dirty collars and wristbands, which may be subjected to a little hand friction. All kinds of fabrics may be washed by it, as it neither injures texture nor unfixes colour. It will remove paint, grease and stains of all kinds. The components of this preparation are cheap—enough to wash thirty-two times for a family of eight or ten persons costing only from forty to fifty cents. Washboards are dispensed with, and a day's hard work reduced to the labour of a couple of hours at most. Besides a number of testimonials from individuals—among them several responsible chemists, who attest from actual trial the qualities of this washing composition—three well-known Provincial journals, the Toronto *Leader*, Guelph *Mercury*, and Ingersoll *News*, having tried it in their respective editorial families, give it the highest eulogy, the last named periodical pronouncing it "the best and greatest discovery of the age for washing purposes." This is good news for housekeepers, and laundresses generally. "Family rights," containing full directions for making and using the composition, may be obtained by remitting one dollar to Rev. W. Warner Clark, Guelph, Ont., or they may be purchased of that gentleman's agents, who are canvassing in various parts of the Province.

What Shall I Do?

By Mrs. Frances Dana Gage.

"What shall I do?" My boy, don't stand asking;
Take hold of something—whatever you can.
Don't turn aside for the toiling or tasking,
Idle, soft hands never yet made a man.

Grasp with a will whatever needs doing,
Still standing ready, when one work is done
Another to seize; and thus, still pursuing
In duty your course, find the victory won.

Do your best for to-day, trust God for to-morrow;
Don't be afraid of a jest or a sneer;
Be cheerful and hopeful, and no trouble borrow;
Keep the heart true, and the head cool and clear.

If you can climb to the top without falling,
Do it. If not, go as high as you can.
Man is not honored by business or calling,
Business and calling are honored by man.

—*Herald of Health.*

☞ Quills are things that are sometimes taken from the pinions of one goose to spread the opinions of another.

Improvement in Cistern Pipes:—An improvement in the arrangement of cistern pipes has been invented and patented by Mr. W. H. Rodden, of Toronto. The peculiarity of the system consists in such a disposition of the overflow and withdrawing pipes that the pure water from the top is pumped out for use, while the overflow is drawn from the bottom of the cistern, where, naturally, the sediment will collect and render the water less fit for use. The new arrangement is highly recommended by medical men. Mr. W. Hewitt is the Patentee's Agent for this city.

About Sun-strokes—Since sun-strokes have been so common, it may be well to give some hints concerning remedies for them. It is said that cold water should be immediately poured over the head of the person thus affected, and that mustard or other stimulants should be applied to the back of the neck, the wrists, knees, and soles of the feet. Of course these remedies should not preclude the calling of a physician in any case where the patient does not immediately rally. As a safeguard against sun-stroke it is well to have something more than the usual covering over the head on venturing into the rays of the hot sun—for instance, a handkerchief, or still better, green leaves in the hat, those of the common plantain being excellent, and frequently used.

Philosophy for the Ladies.—Pie Juice.—The time has now come for fruit-pies, and therefore for pie-juice; and as our readers strive at all points for the practical and useful combined, we intend to offer a suggestion for "the better arrangement" of pie-juice. Some people place an inverted cup in the pie, thinking this catches juice that would otherwise boil over, but that is a mistake, for though juice is found under the cup when the pie has cooled, yet it never entered the cup while the pie was in the oven for this simple reason, the inside of the cup was as hot as the inside of the pie. The case of inverting a cup in the pie does more harm than good, for, as the heat cooks the fruit, it also expands the air in the cup, which tends to blow out the juice from the dish. But if a small hole, say a quarter of an inch, be made in the bottom of the cup, which, of course, comes to the top of the pie when inverted in the dish, the hot air will escape into the oven, and leave room for the juice to run into the cup, which, again, will descend amongst the fruit on the pie cooling. "Now how are we to make this small hole in the bottom of the cup?" says the reader. "Listen and you shall hear," says the writer. "Take a six-inch flower-pot, fill it with dry sand or mould; then take your cup, invert it, and push it down into the mould or sand till only the top is just seen; by which means the inside of the cup is as full of sand or mould as it will be of juice when in the pie; then take a sharp-pointed instrument, like an old pair of scissors or a one-pronged fork, and begin to peck away little by little, and you will soon have a small hole, which can then easily be made bigger before taking the cup from the flower-pot. The sand or mould prevents the cup from cracking or breaking during the chipping process. When the cup is used invert it in the pie, but take care that the small hole is free from the crust." Here is a very simple contrivance that will soon prove itself. A grand plan is to make three pies, one without any cup, one with a cup, and one with the cup with the hole in; then you can see the difference.—*Gardener's Magazine.*

Miscellaneous.

The Borrowing Nuisance.

My neighbour wanted to borrow my shovel—would return it in the evening. Evening came, but no shovel. The next evening it was quietly returned to its accustomed hook in the wood house, the blade covered over one-half its surface with a coating of dry mortar. I pride myself on my clean and bright shovels and hoes. Half an hour's work with an old knife blade, and the use of a sheet of sand paper, restored it.

Another time he was building a pig pen. The posts were too long, and they were very hard, and his saw very dull. Of course he borrowed mine, and he sawed off a nail with it—the posts had been used before. He sent his little boy to return the saw with the message—"Pa would a' sent nad got it filed, but he knowed you allus filed your own saw, and it wouldn't take but a few minutes to sharp it again."

Another neighbour "borrows" the privilege of getting water at my well. The well is deep, and we draw with a windlass. It is hard for my wife to draw up a bucketful, for she is feeble, and to save her, I usually fill the bucket before going away to my business. As the well is in an out kitchen, I leave the filled bucket hanging in the curb. My neighbour sneaks in, empties the bucket, and is mean enough to go away without refilling it. Wife and I conclude it is better to suffer wrong than to have a difficulty with a near neighbour, and so, for the sake of peace, we submit to this wear and tear of soul and body. When the same person borrows flour, for the best article a poor one is returned. Eggs, matches, a "drawin' o' tea," are never returned.

I might increase to great length a record of these examples, but my object is only to illustrate the position taken, that the habitual borrower's code is a lax one. This may be partially accounted for by the fact that the independent, self-reliant portion of the community seldom borrow, and the practice is mostly left to people of the opposite kind. The unscrupulous borrower usually belongs to one of two classes: the easy, shiftless sluggard, or the greedy, grasping victim of avarice. The first borrows with a dim expectation of paying some time, and the hope that he may be able to do so; the other borrows with a full design never to make an honest return if he can avoid it; it shall be clear gain, if he can make it so. Both are knaves, and unreliable in all matters of trust.

Among honest men, borrowing may be made a convenience, and mutually beneficial. Yet I think the question is worth considering, whether it does not demoralize a man—weaken his self-reliance. We get to relying on our neighbours more and more for the thing ourselves ought to procure. On the whole my advice is, to borrow only in cases of great need, when you can get along without doing so.—*North Western Farmer.*

☞ The phrase "Sound on the Goose," originated in Pittsburg, Pa. That city, some years ago, was so overrun with this aquatic fowl that its sidewalks became in an intolerable condition. A public meeting was held on the subject, and at it the extermination of the offending bird was decided on. A charter election soon following, the two candidates for the mayoralty were questioned as to what would be their action in the premises in case of election. The one who was "sound on the goose question" was elected; and from that day the phrase crept into general use among politicians.

Farm of Prospect Hill

TO LET, for a lease of 10 or 12 years, from and after 1st October next:

Being Lot 10, Con. 12, East Zorra, Oxford, 200 acres, occupied by the heirs of the late W. Dawson, Esq.

This is a first-class farm either for cropping or dairy purposes, and is in a high state of cultivation; 100 acres arable; well watered and fenced. Excellent Dwelling House, large Orchard, and extensive Farm Buildings, suitable for dairy purposes. By gravel road, 6 miles from Woodstock; 1 mile from Strathallen cheese factory.

Should an intending tenant take the stock and crop, by valuation, he could have immediate possession. Apply on the premises, or by letter post paid, to

MRS. DAWSON,
South Zorra, Ontario.

Markets.

Toronto Markets.

"CANADA FARMER" Office, July 30th, 1868.

FLOUR AND GRAIN.

THE Produce market during the past fortnight has been quiet; there has been little doing owing to the lightness of the stocks of flour and grain here.

Flour.—The market has been quiet but firm. There has been a fair demand for fresh ground No. 1 Super, but there were few lots in the market. Prices have been steadily advancing. Holders now ask $6.75 for choice brands, and some sales took place at that price, which may be taken as the ruling market price here.

Oatmeal—Selling at from $6 to $6.25.

Wheat—The market is almost bare of spring wheat, for which there has been a fair demand. Several small lots sold at $1.50; there are buyers of car lots at that price. Fall wheat has been offering freely, but there was little or no demand; the market is decidedly dull for fall wheat; lots were offering during the week at $1.50, with no buyers at that price. To-day a car sold at $1.46.

Oats—The market is firm, with good demand; there are not many lots offering; holders are now asking 55c for car lots. To-day 3 cars sold at 53c at Port Hope.

Barley—Nothing doing and nominal.

Peas—The stocks here being almost exhausted, there has been nothing doing in car lots. Prices are therefore entirely nominal.

Hay—Good supply, at $12 to $15 per ton.

Straw—In demand, at $15 per ton.

PROVISIONS.

Pork—Stocks light and held firmly at $23 50 for mess.

Bacon—In brisk demand at 11c. to 11¼c. for Canadian.

Hams—Selling freely at from 14c. to 15c. for smoked.

Butter—The market for the past week has increased in firmness; the dry weather at home, with favourable foreign advices, has caused dealers to buy freely at our quotations. We consider the prospects to depend upon the weather. We quote even yellow at 14c. to 15c. Selected parcels at 15c. to 16½c.

Eggs—Lower; offered at from 11c. to 11½c.

Cheese—Quiet without decided change in prices. We quote 9½c. to 11c.

HIDES—Green, rough, per lb., 5½c. to 6c.; do. green, inspected, 7c.; do. cured and inspected 7½c. to 8½c. *Calfskins*, green, 10c.; do. cured, 12c.; do. dry, 18c. *Lambskins*, green, 15c.; do. pelts, 10c.

THE CATTLE MARKET.

We quote, per 100 lbs., dressed weight:—1st class cattle, $6; 2nd do. $5.; 3rd $4. *Sheep* have been in fair supply. 1st class, $4.; 2nd do. $3; 3rd do. $2. *Lambs* have been in demand. We quote: 1st class $2.50 each; 2nd, do. $2; 3rd, do. $1.50. *Calves* have been offering freely. There has, however, not been much demand. 1st class $6 each; 2nd, do. $4; 3rd, do. $2.

Montreal Markets, July 30.—*Flour*, superior extra, $7 50; Extra, $6.80 to $7; Fancy, $6.60; Welland Canal superfine, $6.65; Superfine No. 1 Canada Wheat $6.60 to $6.70; Superfine No. 1 Western wheat, $6.30 to $6.40, No. 2 do, $5.85 to $6.10; Bag flour $3.30 to $3.60. *Wheat*—Canada Fall, $1.45 to $1.50; Canada Spring, $1.55 to $1.60; Western, $1.42½ to $1.46. *Oats*—Per 32 lbs., 44c. to 45c. *Barley*—Per 48 lbs., 90c. *Butter*—Dairy, 15c. to 17c.; store packed, 13c. to 16c. *Cheese*—Factory, 9c. to 10c. per lb. *Ashes*—Pots, $5.65 to $5.70; Pearls, $6.60 to $6.65. *Pork*—Mess, $24.75 to $25; Prime Mess, $16.75; Prime, $16. *Peas*—$1.12½ to $1.15. *Rye Flour*—$5.75 to $6.

Guelph Markets, July 30.—Fall wheat, per bush, $1 40 to $1 45; spring wheat, $1 44 to $1 46; oats, 50c to 51c; peas, 65c to 70c; barley, 70c; wool, 26c to 27c; hides, per 100 lbs, $6; beef, per 100 lbs, $7 to $8; straw, per load, $3; hay, per ton, $7 to $8; eggs per dozen, 12c to 13c; butter, per lb., 15c to 16c; potatoes, per bag, $1 25 to $1 50; sheep skins, 20c to 30c.

Hamilton Markets, July 30, 1868.—*Fall Wheat*, per bush. $1.40 to $1.47; Spring Wheat, $1.38 to $1.40; Barley, $1 to $1.5; Oats 60c. to 65c.; Peas 80c. to 85c.; Corn 65c to 70c.; Potatoes per bag $1.25 to $1.50.

Milwaukee Markets.—July 29, noon.—Wm. Young & Co.'s report.—Wheat—Receipts, 6,000 bushels; shipments 6,000 bus. No. 1 wheat firm at $2.14; No. 2 do. at $1.78 to $1.79. Flour quiet and unchanged. Pork firm at $28 to $28.25.

Chicago Markets, July 29, noon.—William Young & Co.'s report.—*Wheat*—Receipts, 29,000 bushels; shipments, 1,000 bus.; No. 2 Wheat firm at $1.80 *Corn*—Less active at 94¾c. to 95c.; receipts 84,000 bush shipments, 51,000 bush. *Pork*—Firm at $28.25 to $28.50.

THE CANADA FARMER is printed and published on the 1st and 15th of every month, by the GLOBE PRINTING COMPANY, at their Printing House, 28 and 22 King Street East, Toronto, Ontario, where all communications for the paper must be addressed.

☞ Subscription Price $1 per annum, (TWENTY CENTS,) payable in advance. Bound Volumes for 1864, 1865, 1866 and 1867, may be had for $1 30 each. Subscribers may either begin with No. 1 of the present Volume, or with the first No. of any preceding volume. No subscriptions received for less than a year, and all commence with the first number for the respective years.

CLUBS will be furnished at the following rates:—

TEN COPIES FOR ..... NINE DOLLARS.
TWENTY COPIES FOR ..... SIXTEEN DOLLARS.
FORTY COPIES FOR ..... THIRTY DOLLARS.
ONE HUNDRED COPIES FOR ..... SEVENTY DOLLARS.

To Agricultural Societies ordering in excess of 125 copies, THE FARMER will be sent at SIXTY CENTS.

THE CANADA FARMER presents a first-class medium for agricultural advertisements. Terms of advertising, 20 cents per line space. Twelve lines' space equals one inch. No advertisement taken for less than ten lines' space.

Communications on Agricultural subjects are invited, addressed to "*The Editor of the Canada Farmer*," and all orders for the paper are to be sent

GEORGE BROWN,
Managing Director.

VOL. V. NO. 16. TORONTO, CANADA, AUGUST 15, 1868. POSTAGE FREE.

The Field.

Cultivating the Thistle.

To the Editor of THE CANADA FARMER:

SIR:—There are two things at this time, in reference to the Canada thistle, of which I would be glad to say a word worthy of your notice. First, before the Thistle Act was passed, in 1866, Path-masters always mowed down the thistles growing on their respective roads, but the past two years they have ceased to do so (at least in this locality). There are now growing on embankments hideous avenues of thistles, formidable enough to make fences, and they could scarcely ever present a more vigorous growth; the dry weather has had no retarding influence on their perfect development. A few remarks, though having a local reference, might have a general bearing. Then supposing we start from the city westward, we find long before quitting the limits, vacant lots, (as they are called) completely occupied by thistles, all of which might have been cut down the last week in June for a very trifle. Passing on to a little west of the Lunatic Asylum, and joining the Grand Trunk Railroad on the south side of the lake shore road, is a large portion of the garrison common, which some two or three years ago was cultivated, but is now again abandoned, and here you see the thistle in its greatest state of perfection. Some think they might be made useful in the event of an invasion from that quarter, because they could place in ambush several regiments of soldiers, while others think intrenchments would answer as well; however, military authorities ought to know best. One thing is certain, there is enough seed on that one spot to stock the whole Province. The next remarkable thistle forest you come to (still going west) is a little before you come to the Etobicoke river, where is a large field that has been abandoned to the thistle for five years, and they visibly began to deteriorate for want of proper cultivation, and this year they have got it, by the ground being ploughed and sown with barley. Ploughing the ground that is infested with thistles, after they have ripened their tops (in the fall or in the spring), is the unfailing way to strengthen and increase their number. Take a large district as a whole, it is safe to assert that in the past seven years the thistles have doubled their numbers. In all extreme cases it is wrong to waste time in the fall or spring, to plough the thistle ground, or sow it with grain (for a season would be comparatively lost); but let them grow till after midsummer, then mow them with the mower or scythe, or with both, and as soon as dry, burn them, after which plough, and if need be, get some help. After this, use the cultivator at least twice, then sow buckwheat, with two good harrowings, and the thistles will be at least three parts subdued, and not one can possibly ripen seed. As soon as the crop is ripe, cut and remove it, and without loss of time, use the cultivator (not the plough), which will take off the heads of all remaining thistles (let none escape); also it will cause to grow every grain of wheat that might have shelled out, and so avoid future trouble with the next crop. A first class crop of buckwheat will just pay the farmer all expenses, and leave his land in good condition for spring wheat, to be seeded down with clover. All the labour attending the cultivation of the foregoing crop will not in the least interfere with the grain harvest, or cultivating, or collecting the farmer's root crop. We find here now and then, and I suppose it is so everywhere, sapient legists, who boast and say they can drive a coach and six through any Act of Parliament, and the Thistle Act especially, arguing "a man may grow what he likes on his own land." Well, suppose the thistle grower is allowed to possess this right, then let the legislature come down upon him and spoil his market for this class of produce, by inflicting a fine heavy enough to allow a portion of it to go to the informer, to make it worth his while to look after the vendors of this nuisance. There are some who care not for consequences, and, so long as they can get the same price for thistle-heads as for grain, or the same price for the dead thistle plants as for hay, and different sorts of straw (especially pea-straw) they will continue to do so; but let the law plainly designate all such transactions as obtaining money under false protences, with a bill of pains and penalties attached, and the farmer would quickly give up growing the vile stuff, because there would be no market for it, and the whole community would be benefited by the change, and none more than the farmer himself. Secondly, I wish to say one more word in reference to seeding of the Canada thistle. I have discovered this much: that farmers generally do not know a thistle seedling plant while in its infant stage of two leaves. To all such I would say, beg or buy a pinch of lettuce seed and sow it, for the young seedling is precisely similar to the young thistle, being closely related to each other as species. I have recently received a Chicago newspaper, in which I saw a significant heading to a paragraph, namely, *The Canada Thistle*. The writer implores one and all to lend a helping hand, to spare *no expense* to arrest and exterminate its presence, for it has made its appearance in three places, at least, in Illinois. The reason assigned for this vigilance is, its presence will depreciate the value of land twenty-five per cent. I was not aware till recently of that general incredulity among farmers in disbelieving the propagation and extension of the thistle by its seeds. To reason from analogy and from facts of every year's experience, I see no reason to conclude that the thistle seed is less certain to grow (when placed in favorable circumstances) than any other weed; and if so it might fairly be inferred there is not one in a million that is not capable of producing a plant. But if they all grew, it would be woe to the inhabitants of *terra firma*, at least; for to multiply every year's product for twenty-five years by eleven thousand (the product of one thistle) would produce enough to sow thickly the whole globe, and then there would be sufficient left to build a bridge across the Atlantic, although the waters should be miles deep. The learned tell us that one pair of red spiders would soon produce a quintillion, but then there are other animals that would as soon consume them, and birds eat an enormous quantity of thistle seeds. Thistle seeds, doubtless, are endowed with the same powers in common with other seeds, to preserve their vitality when buried deep in the ground, and when divested of their hoary trapping can fall down in cracks in common with other seeds. But I anticipate some will say "let us have facts and not theory." Here they are: Seven years ago I reclaimed a portion of a swamp where no thistle ever grew nor could any animal pass over it. In 1865 I had to abandon part of it (being cultivated with the spade), but in the fall there was a heavy crop of grass, &c. On mowing it (to my surprise) I found it full of thistles half a yard high, and on examining them I found every one of them were seedlings. Every year we make up a hot-bed in the spring, and collect some of the best earth we can get to put on the top, and the seedling thistle has never once failed to be thickly represented among a multifarious mass of weeds. Last year, while walking across a field in company with a farmer, he stooped down and picked up something; it was a thistle head, and full of young plants. He remarked that "some people did not believe they grew from seed, but seeing was believing." I have done the same thing myself without being curious enough to count their number. This spring a neighbouring farmer called on me, and, of course, we had some talk about the thistle. After referring to this fact that farmers did not believe the seeds grew, he said: "I was determined to put it to a test, I took a thistle-head and planted it, and there came up just fifty plants." I live next to a neighbour who don't believe in bothering about thistles at all, and enormous quantities every year go to seed, of which I get a large share. This spring I ploughed up a meadow, having been down five years, and the seedling thistles sprung from the upturned soil by thousands, the seed having lain buried all that time; and if the vitality of the seed was preserved for five years so it would be for fifty, or five hundred. This spring I dug up a piece of ground that had never before been disturbed by plough or spade, from which grew thistles and an enormous lot of mullen. I have now one *seedling* thistle growing from the top of a stump, which I hope (for a time) to preserve. Before bidding adieu to this subject permit me to refer to friend Peter Shisler's last letter on this subject. He speaks of the seeds of thistles as imaginary foes, but the plant itself as a real one, and asserts: "the most careless could not fail to observe that its principal mode of pro-

pagating itself is by the root;" and as a proof of this, he refers to my first letter, wherein I related an experiment of a thistle being planted in a garden, having produced sixty plants in the spring, after (supposing) they had extracted all the pieces. Let it be observed, this thistle was placed in an artificial position, with rich, damp, and unctuous earth, with no other plant to share or obstruct the ramification of its roots, which cannot happen in a state of nature. I once grew a single oat plant, to see what could be done by high cultivation. I petted it all I knew how. It produced seventy-five stalks, which numbered three thousand grains; but, like the thistle, it could not be done in an ordinary way. There is, moreover, in my mind some ambiguity as to the precise application of his expression, "They are propagated by careless cultivation," which, perhaps, he would have the goodness to explain.

PUBLICOLA.

Building Stone Fences.

A New Hampshire correspondent of the *Genesee Farmer* writes as follows on this subject.

"A stone fence built upon a light, porous soil, if laid with tolerable skill, will stand for a long time; but to construct one that will stand upon a wet, springy tract of land, especially if it is sloping, is far more difficult. The action of the frost will gradually loosen the foundation, and, when the ground becomes soft in spring, the stones are crowded out of place, and in a few years the fence is in ruins. When the line of direction is east and west, fences are injured most by frost, for the ground upon the south side is thawed earlier in spring.

"These difficulties, however, may be overcome. If the proposed fence is to be on a loamy soil that is not very wet, it will be sufficient to make a small ridge or embankment, say four feet wide and one foot high, to build the wall upon; but if the land is spongy, dig a ditch three or four feet wide, and deep enough to remain uninjured by the frost; fill it with small stones, or partly fill and cover, and then your fence will have a foundation which cannot be shaken.

"The foundation well prepared, the next thing is to have the fence well laid. Only such stones should be used as will be firm and afford a good surface to build upon. They should be so laid as to secure these results, and endeavors should also be made to have each principal stone, in all except the lower course, rest upon two below it. It requires no little skill to build a stone fence well, but by following these rules one is not likely to go far out of the way; and when it is once made it is very durable."

Another correspondent in Oneida county, N. Y., writes as follows, adding that stone walls constructed according to this method in the most frosty sections of Wales have stood for centuries:

"Plough four furrows six or eight inches deep and ten inches wide; take all the sods, or turfs, and lay them on one side—also all the loose earth that is easily taken up with a shovel, and lay it on the same side with the turfs, both to be on the opposite side from the stones for the wall; then commence setting stones on the sides of the trench large enough to rise about three or four inches above the outside surface; then fill in with small stones until within two or three inches of the top of the border stones; then throw on a few shovelfuls of fine dirt, passing the shovel over it to make it level; then commence laying on the border stones, being careful to have them tip a little towards the centre; then commence again with the small stones and dirt as above described. When the dirt is used up, cut the turfs at suitable lengths and lay lengthways of the wall, bringing the edge of the turfs close up to the edge of the border stones, filling the middle space with small stones. In this way there will be about two tiers of dirt and two of turf—if more, all the better.

"It will be seen that this wall will be about forty inches on the bottom and twelve inches across the top, when raised about four feet in height. If there is no stone handy large enough to reach across the top, continue on as before until the top is well rounded off."

Canada Thistles.—When to Cut.—The N. Y. Agricultural Society has received a communication from John Ferguson, of Caldwell, giving his experience in fighting Canada thistles. He ascertained that cutting them, as he did, August 17th, 18th, 20th and 24th, was sure to kill them. He cleared his farm entirely by pursuing this course of cutting. There is a general concurrence in the opinion that August is the right time to mow thistles for the purpose of killing them.

Sandy Lands.

The common opinion is that the sandy lands of New England are its poorest lands—and in conformity with this opinion, thousands of acres are suffered to lie uncultivated, to spring up to wood if they will, or afford a scanty crop of wiry grass to sheep that are allowed to run over them. If cultivated at all, it is with rye, generation after generation, either every year, or every alternate year, as the land may hold out, and without the application of manure! All this is wrong, both in theory and practice, and would not be continued if we better understood the nature of soils and how to treat them.

Sandy lands are usually among our most *level* lands, and are cheaply cultivated on this account. They are light, and are ploughed at one-half the cost of adhesive soils. Twice as many acres of them may be hoed in a given time as can be in heavy and stony lands. Sinclair says sandy soils of a good quality, under a regular course of husbandry, are of great value. They are easily worked, and at all seasons; they are cultivated at a moderate expense; are not so liable to injury from the vicissitudes of the weather; and in general are sufficiently retentive of moisture to produce good crops, even in dry summers.

Sandy lands may be improved in several ways, and the plan adopted should depend upon surrounding circumstances. If they are adjacent to a clay pit, clay may be used; if near a deposit of muck, muck may be used, or both may be employed with decidedly beneficial results. If the land is too far from such sources of supply, then another plan may be adopted. It may be restored by turning in crops, green or dry, where they will decay under the surface. Sandy lands may, therefore, be reclaimed, wherever situated, and brought into a fertile condition, and at a fair profit.

One plan of operation is to plough under green crops, such as oats, millet, buckwheat or clover, when the crop is in bloom, reseed at once and plow in another crop the same year. If the land has been dressed with clay or peat muck, this operation greatly hastens the work of reclamation. Dana says that it is the experience of some practical men, that one crop allowed to perfect itself and die where it grew, and then turned in dry, is superior to three turned in green. The whole result is explained by the fact that dry plants give more *geine*, (the word means "earth," or the product of decaying vegetable matter) than green. Green plants ferment—dry plants decay. A larger portion escapes in fermentation as gas, and more volatile products are formed than during decay. The one is a quick consuming fire—the other a slow mouldering ember, giving off, during all its progress, gases which feed plants and decompose the silicates (that is, sand, flint, quartz) of the soil. These hard silicates in the soil have their uses, and an important part to perform. It belongs to us to supply them with vegetable matter. Feed them well with muck, straw, meadow hay, rushes, flags, or almost any other vegetables, and their decay will "cause an evolution of carbonic acid gas; this decomposes the silicates of potash in the sand; that potash converts the insoluble into soluble manure, and lo! a crop." When once a crop is obtained even on the poorest sands, there is the nucleus of fertility, and fair crops may be obtained from it perpetually. —*N. E. Farmer.*

The Treatment of Tree Seeds.

Our people are at last waking up to the importance of trees, whether for fuel, timber or shelter. The subject is already beginning to have a literature, as we last month noticed the "Forest Tree Culturist" of Mr. Fuller. Upon looking over our correspondence, we find a great many queries as to the proper method of treating particular tree seeds, and we can best answer these queries in a lump. These seeds may be divided into two classes, one including those that must be sown as soon as ripe; the Elm and the Red and White (or Silver) Maples ripen their seed in the spring. As we have shown in a former number, the failure with these seeds is due to want of knowledge of the fact that they ripen in June, and that they must be sown at that time. If kept until the following spring, these seeds lose their vitality and fail, but if sown as soon as mature, they make strong young plants the first year. Other seeds needing immediate sowing ripen in autumn, and these are to be treated as nearly as possible as nature treats them. If late in autumn we look beneath the fallen leaves of an oak tree, plenty of acorns will be found from which the radicle has protruded, showing that germination has already commenced. This will give the hint as to the proper treatment of acorns, which are to be planted shallow, and the bed protected with a good covering of leaves or other mulch. Chestnuts, Horse Chestnuts and Buckeyes, Tulip Trees, Hickories and Walnuts are treated in the same way. Hickories and Walnuts are said to do well if mixed with earth in a cool cellar during winter, and we have succeeded perfectly well with Horse Chestnuts put in a box of earth and exposed to the weather all winter.

Seeds that are kept over winter should be preserved at a low and even temperature, and of course be quite dry before put away, to prevent mould. The following are among the commonly planted seeds that are usually to be had of seed dealers: Honey Locust, Osage Orange, the Ashes, Larch, Deciduous Cypress, Maples (except red and white), Spruces, Pines, and other evergreens. Honey Locust, if fresh, will grow without preparation, but if old, it should be scalded. Osage Orange must be sprouted; the others merely need to be sown in a light, rich soil. Evergreens are very tender when young, and are apt to be sun-scorched. These are best sown in beds where they can be shaded by a lattice work screen made of laths.

Young trees, like other young plants, require care, and no one need sow the seeds with the expectation that they will take care of themselves. Weeding, cultivation and thinning must be duly attended to, and if the little trees are likely to suffer from drouth, the ground should be covered with a good mulch of saw-dust. If they are left in the seed bed over the first winter, they will need to be covered with leaves. —*American Agriculture.*

Marl.

In the southern portions of New Jersey, Delaware and Maryland, there is used with success a valuable natural fertilizer with the above name. New Jersey in particular is underlaid with it, and in the largest and finest belt there are thousands of tons exhumed from the earth annually, and sent to all parts of the State. The Squankum enjoys the best reputation, being of a deep green colour, and containing a much larger proportion of valuable ingredients. It has been proved by years of experience to be the best and cheapest fertilizer for all kinds of crops. Immense quantities are taken out at the above place, and delivered along the line of the railroad at small cost. A dressing of one hundred to one hundred and fifty bushels is applied per acre once in three years. Its value is found in the fact that it contains nearly all the substances necessary to make up the ash of our common plants. Prof. Cook, State Geologist of New Jersey, says: "A comparison of the analysis of marl with that of the ash of plants shows how abundantly it supplies the mineral substances needed for the growth of vegetation. The following is the analysis of Squankum marl:

Water	19·600
Silica	51·162
Protoxide of Iron	18·200
Alumina	6·100
Potash and Soda	4·274
Lime	3·478
Magnesia	2·037
Phosphoric Acid	4·457
Sulphuric Acid	0·329"

The growth of white clover upon marl-heaps has come to be a test of its character. Those marls containing lime soon become covered with a spontaneous and luxuriant growth of clover.

Marl can be purchased in any quantity, in New Jersey, as low as $1 50 per ton, and in Delaware and Maryland at from $2 to $2 50 per ton.

The amount of Potash and Soda in a ton of Marl is 85½ lbs., which, at 6 cts. per lb., amounts to	$5 13
Phosphoric Acid, 90 8-10 lbs. at 8 cts.	7 20
Value of a ton of Marl	$12 33

Besides these elements there is always a small quantity of ammonia. The sulphuric acid unites with the lime, forming sulphate of lime, also a valuable fertilizer; besides these, there are plaster and iron; but, at least estimates, a ton of marl is worth at least six times the price it costs in the above sections.

Hardening the Mould-Board of Ploughs.—A new metal has been discovered for the manufacture of the mould-board of ploughs which gives them all the hardness and temper of steel, in combination with the toughness of iron. The mould-board (good Iron) is heated and dipped into molten iron. It remains there ten seconds, when the two surfaces become heated to a white heat, while the centre is not heated through. It is then immediately dipped into water, and [illegible] come out harder than the highest tempered steel, while the interior is still iron and retains all the toughness and strength of the iron. The advantage claimed for this invention is that the plough made by the process will take the finest and hardest polish, and they will be tough enough to endure any reasonable knocking about in stony soils.—*N. Y. Weekly Herald.*

Thinning of Turnips.

A correspondent of *The Farmer* (Scottish) writes as follows, on the above subject:

"Turnips have for a long course of years been generally thinned with the hand hoe; and in thinning, great care has been taken to have the plants left all laid flat upon the ground, with only a very feeble hold of the soil. The method is still in full practice by a number of farmers at the present day; but a considerable number have found, from experience, that this is not the best mode of management. The new, and at present best method, is the *hand thinning*, which is gradually growing in favour, and countenanced by several extensive farmers. It is allowed to be as speedy a mode, when performed by expert hands, as the common old hand-hoeing system. This new method is performed by the thinners; boys and girls can do the work admirably, and at little expense, and at every proper distance for a plant to be left, a good-sized one is seized by the left hand, while the right clasps and pulls out what are unnecessary. By this system the plants are left less injured and with firmer hold of the soil than when thinned with the hoe, which causes them to come forward more rapidly than when laid prostrate and loosened. For swedes the plan has been found to be advantageous. It is but natural to suppose that, where the plants are laid over and loosened, even allowing them to take but a short time to rise again, those never laid over must be a stage further advanced by the time the others have got upright, besides they are less liable to injury by being tossed about by high winds. The experiment has been tried by several farmers, and the result has proved favourable. The use of the hoe in cleauing is, nevertheless, necessary, and this is a light matter and easily performed. One trial will be found convincing."

Whereupon the Editor observes:

"The mode of thinning turnips mentioned by our correspondent may be new in his neighbourhood, but we adopted it more than twenty years ago, not indeed from any idea that it was an improvement, but because we were so situated that we could not get hands who were expert in the use of the hoe. We found, however, that it was a good plan, and continued to practise it; but the ground must be gone over with the hand-hoe very soon after the plants have been thinned."

The New Double Furrow Plough.

This recent invention was tried on Saturday last, through arrangements made by Messrs. Benjamin Reid & Co., on a field at Rubislaw, near Aberdeen. The plough is the invention of Messrs. Thomas Pirie & Co., millwrights, Longside, Aberdeenshire, by whom it was patented and first exhibited at the show of the Royal Northern Agricultural Society in July last. There it received commendation from the judges, and was set aside for trial in autumn. At the trial, which took place on the farm of Auchterellon at the same time as the competition in reaping-machines, held under the auspices of the Society, its merits were seen and appreciated. One man can superintend the plough and also drive the horses. By means of two iron handles or levers, fitted with regulating screws—one regulating the first plough, the other for regulating the second—he directs the depth of the furrow slice, which can be altered at any time without stopping. A third lever is used to move the front or steerage wheel, by which the plough is readily turned. On this occasion, the size of furrow was six by nine inches. The coulter and mould-boards are of cast-steel. Applying the dynamometer, the draught was found to be favourable as compared with that of the single plough. Here the average draught was nearly six cwt., and the common plough, when tried on the same ground, averaged four and a half. Tried immediately after on land after turnips, the difference was rather more marked; so that it may be stated generally that the draught of the double furrow plough on such land is much about the same as the common plough on lea. Of course, the same dimension—six by nine inches—was adhered to in making the comparison. Trials made on heavy clay lea, in different parts of the county, show a similar difference of draught between the double and the single plough. On such, it is calculated, three horses draw the former with more ease than two can do the latter. And then, as the amount of work done, with two horses in eight hours, one double plough turns over two imperial acres of light loamy lea; and as an instance in point, on the farm of Tipperty, near Ellon, some weeks ago, with three horses, strong land in lea was ploughed with a furrow of seven inches by nine and a half inches, at the rate of two and a half acres in ten hours.—*Farmer* (Scottish.)

Top-Dressing Grass, &c.

The agricultural correspondent of the *Inverness Courier* says, with reference to the use of artificial manures for the purpose of top-dressing grasses, &c: "We see that everywhere, almost, top-dressing is now the rule for much of the grass. Nothing pays better when a proper opportunity is taken for doing it, and suitable manures are applied, because whether for pasture or hay, a thick sole, and a vigorous start, is half the battle won. If for hay, we have a prompt return in the stack; if for pasture surely it is wiser to increase the growth on one's own land than to send half the cattle away to enrich a "superior grass park" let by somebody else for your money and their manure. We know very little land that would not repay the farmer for top-dressing his first year's grass at any rate. For of course all the conditions that hold good for increasing crops in general, hold good as regards grass; the better, and richer, and drier the soil, the more will the profit be, notwithstanding the fact that very enormous crops of grass grow in the sea-sand, where, as a rule, cereals with the same treatment would do no good. It was their experience of this fact that brought those Ayrshire farmers to grief, of whose wonders we heard so much ten years ago. Not that they were farming sea-sand, but that they mistook the effects of over-enriching cereals by top-dressing. In our own time we have succeeded in illustrating the process. On a farm of the lightest soil—if it might be called soil at all—we broke up four or five-year-old lea, and with a little labour and a great dose of guano, got a spanking crop of turnips. We gave the whole crop to sheep, sowed barley, and had the most beautiful and bulky growth the eye could desire. Very proud we were of our farming, and we went on talking largely about our precious field till harvest approached. One day we made the startling discovery that some of the long and handsome ears happened to have no grain in them, and we pursued our researches long enough to become aware that perhaps the less we said about the whole affair the better; for, in fact, that field which looked five quarters did not thrash out *two* bushels! We had stimulated the poor weak soil into a fever, and grown grass (in fact), and left in it no strength for growing grain. Of course it is very possible to waste top-dressing even on grass, for if a long drought succeeds the time of application the manure will be nearly useless."

The Barberry as a Hedge Plant.

P. Allyn, of Benton Harbor, Mich., writes to the New York Farmers' Club as follows:

"I want to say a few words about the barberry. One fact is worth half a dozen guesses, and I have experimented on barberry for ten years, and cannot see its character as some do. Ten years ago, or about that time, I planted one hundred barberry bushes in Delaware county, Iowa. The following winter, on thirty different days, the mercury sunk down from 10° to 30° below zero, and it did not injure the barberry. This ought to establish its hardiness. Four years ago I planted ten rods of small barberry plants for a hedge on my place. That hedge now appears much like a perfect fence. Man or beast would try more than once before passing through it. Two years more of such growth as it had last year would make it hog-tight, horse-high, and bull-strong. As to its blasting crops, I have raised wheat, corn, sugar cane, and many varieties of fruit right along beside the barberries, and the only thing I ever knew blasted was a few English gooseberries, which always blasted even when far away from the barberries. A Massachussetts man complains of the seedlings springing up. I will pay him $100 for 20,000 such plants, delivered to me next fall. One writer complains of their sprouting at the root, and becoming a nuisance. I deny that one plant of the barberry ever sprouted from the root. It does, it is true, throw up each year straight sprouts from the collar of the plant. The second year said sprouts throw off lateral branches, which lock and interlock with the previous growth. All of these sprouts unite below the collar in one central root, which at the depth of eight or nine inches branches out into proper roots, but I have never seen one bud on the root of any plant of the barberry. Let no one send to me for seeds or plants, for I have neither for sale. I do, though, fully believe that the barberry is yet destined to become the great hedge plant of America.

The Early Rose Potato.—Our American exchanges give a very flattering account of this new potato. Specimens of this year's growth are described as large and of excellent flavour. It is thought it will take the lead of all the early sorts.

New and Simple Potato Digger.

A potato-digging machine, easy of construction and light of draft, is thus described by a correspondent of the *Country Gentleman*:—

It consists of a wooden bar four feet long, into which are inserted from the bottom five steel teeth. These teeth, which are of bar steel, rounded on the upper surface and brought to a point at the working end, are put through the wooden bar and secured by nuts, so they are easily removed. From the wooden bar to the principal curve in the teeth is about five inches, and from this curve to their outer extremity they form an angle of about fifteen degrees. An iron rod, rising about two feet and a half from the wooden bar, and fastened to each end of it, forms the handle. Trace chains, from six to ten inches long, pass from each end of the bar, by which to attach the horse to the machine, which is done by hooking these chains to the traces, so no whiffletree is used.

As to the efficiency of this digger, it is alleged that it does its work well and rapidly, inasmuch that two men dug forty-three bushels of potatoes with it, and put them in a waggon, in three hours, last fall. This labour, by the same men, would dig and put in waggons over 140 bushels in ten hours.

Ashes for Wheat.

A correspondent of the *Rural Gentleman*, in Delaware, writes strongly in favor of ashes to prevent rust in wheat, and from experience has found them of great value. As to the effect of ashes, he says they have, like Shakespeare's "sherry sack," a "threefold operation;"

1. The ashes operate as a manure upon the wheat, even in the limited quantity of eight bushels per acre.

2. They push the wheat forward several days, and in time to escape the hot, sultry days which often prevail about the time of the "heading out" of the wheat; and

3. They strengthen the stem, giving it substance and solidity.

I may add one or two more properties of the ashes; they afford just that kind of pabulum or food which is best for the development and perfection of the grain, and will, in my opinion, also prevent the ravages of the fly in wheat. I would here venture the remark, that whoever once tries this experiment will thereafter spread his wood ashes upon his wheat, as above indicated; and, in so doing, he will effectually guard against and prevent "the rust" in his wheat.

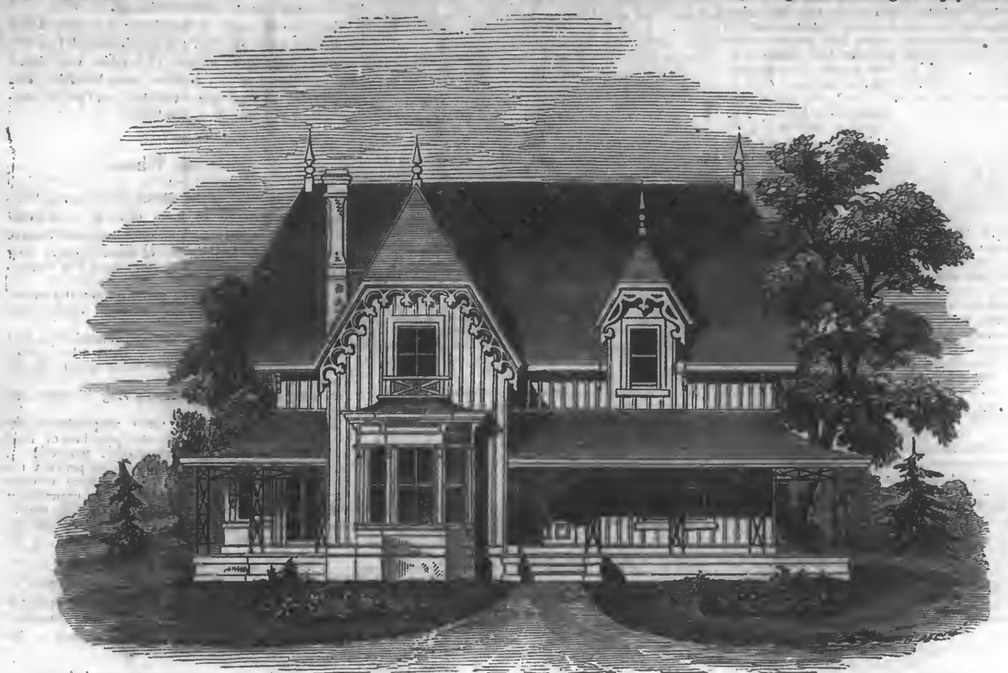
Great Yield of Barley.—A California farmer by the name of Gridley, who cultivates some 3,000 acres of land, recently harvested fifty acres of barley, which it is reported averaged eighty bushels to the acre.

Irish Oats.—We were pleasantly reminded of the "old country" the other day by seeing a magnificent sample of oats brought to our office by a gentleman, who had just arrived from Ireland and brought the specimen to show Canadians what could be raised in spite of drought and adverse seasons; for crops of all kinds have been exposed throughout the whole of Great Britain to the same scorching ordeal that we have experienced in this country. Such, however, is the abundant moisture of the "Emerald Isle," that we are informed they have suffered less from the drought than the sister country; and certainly the sample before us speaks well for the fertility of the soil and the skill in culture that could produce so luxuriant a growth. The straw is between six and seven feet long, stout and strong in proportion, and the heads are heavy and well filled. The sample was taken from the farm of W. Watson, Esq., of Ballanrath, near Edenderry, in King's County, and was brought over by Mr. R. J. Tackabury. Mr. Watson, we understand, does not trust solely to the natural richness of the land on his estate, but makes a liberal use of manure. To produce like results, we must treat even the virgin soil of Canada on the same principle.

Rural Architecture.

Cheap Country House.

We again present our readers with a design for a country house, carefully and completely drawn, both as to elevation and plans, so that any good builder using the accompanying illustrations, as working drawings, could erect what would be allowed by most persons to be a very picturesque as well as commodious dwelling. We may state that a gentleman in England, wishing to put up on his estate a frame building such as we use in this country, selected this design for his purpose, and has had all the timber framed in this country and sent out, to be put up by a Canadian workman on its destined site. The architect, builder, and material are consequently all Canadian. The structure will present an unique appearance amid its English surroundings.



The design is adapted for a dwelling of more moderate cost than some of those that have recently appeared in this journal, and will doubtless be quite within the means of many of our farmers. It is very important in this country to secure in connection with a dwelling house plenty of verandah room, and large and airy apartments capable of easy and complete ventilation. During the recent sultry weather, every one who had an outside porch or verandah was certain to be occupying it in his hours of rest and leisure, and those who had not this luxury were disposed to envy their more fortunate neighbours, or at all events would mentally resolve that if ever they built a house they would have a verandah. These appendages, besides being ornamental and giving relief to plain walls, are pleasant as an out-door retreat in hot weather, serve to keep the interior cool, and will be found very convenient also in wet seasons, especially where there are children.

As the accompanying design was prepared for a country house, all these convenient arrangements have received particular attention, at the same time that economy in construction has been kept in view. By referring to the drawings it will be seen that the house is entirely surrounded by a wide and airy verandah, the roof of which is supported by light lattice posts.

The dining-room projects from the main wall, and is furnished with a bay window, where views can be had to the south, east, and west. The drawing-room, which connects with the dining-room by sliding doors, also projects, and is furnished with a bay window similar to that in the dining-room, looking north, south, and west. These rooms are each sixteen feet wide, and eighteen feet long, and furnished with fire-places. To the right of these rooms is a spacious hall, nine feet wide, running right through the house from back to front; in which are placed stairs leading to the upper rooms. Opposite the drawing-room is the library, also furnished with a fire-place. In the rear of the stairs, and opposite the dining-room, is the kitchen, connecting with the main hall by a short passage; and on each side of this is a pantry, one opening out of the kitchen, and one off the main hall. On the first floor—the chamber floor—there are five bed-rooms, and a dressing-room connecting with the best bed-room, and three wardrobes. The three principal bed-rooms are provided with fire-places. Although the upper story is termed a half one, the bed-room ceilings are ten feet high, and only a small part of the slope appears in the rooms.

The exterior will have a very pretty appearance, broken up as it is with projections, bay windows, verandah, and steep-pitched roof, &c. By lovers of the picturesque a house of the above description, situated on a fine smooth lawn, and surrounded with groups of shrubs and trees, would be thought the height of comfort and elegance. Such a house, though commodious and ornamental, need not be an expensive one. If properly built with timber, and placed on a brick or stone foundation, it would last for many years, and if due regard were paid to the selection of seasoned lumber, and properly plastering the walls down to floors, a warm and durable house would be the result.

It will be seen, by referring to the elevation, that it is the intention to build this house of timber, and framed in the usual manner, the sills of the frame resting on brick or stone foundations, whichever may be most conveniently procured in the locality. The outside will be sheeted with one-and-a-quarter tongued and grooved upright boards, and the joints covered with inch by three-inch batten. The interior can be finished to suit the tastes of those who may build.

Painting Buildings and Farm Implements.

Farmers should learn how to paint their buildings, tools and farm implements in a neat and workmanlike manner; and they may just as well do all their own painting and varnishing as to pay some painter twice as much as it is actually worth to perform a given job. In the spring, and during warm days in winter, and at any other season of the year, if a farmer has only a little instruction in preparing paint and putting it on, he, and those in his employ, may do all the painting, when they could do nothing else which could be of much account.

Farmers are quite apt to think that it requires a vast amount of wisdom and skill to prepare paint and put it on, and some painters like to make them think that it is far better to pay a very exorbitant price to a painter to have an implement painted than to undertake to do it themselves, and then fail. But there is no danger of falling in ordinary painting. Suppose the first, or even the second coat of paint be a little too thick or too thin when it is put on, after it is on it will preserve the timber just as well—which is the chief object in painting—and no one will care to know, so far as "looks" are concerned, after the implement has been used twice, whether a novice or an experienced workman painted it.

Common paint-brushes are made of the bristles and coarse hair of swine. The long bristles are assorted with no little care and judgment and placed by themselves, and those of a corresponding length are put in another place. They are then combed out, straightened, and fastened to the handles. For ordinary painting, those having the longest hair are preferable, and those brushes that are of an oval form are preferable to round ones. When the handles are round, it is best to flatten them a little so that the brush in painting will wear on two sides only. A painter can usually paint better with a brush of an oval form than with a round brush.

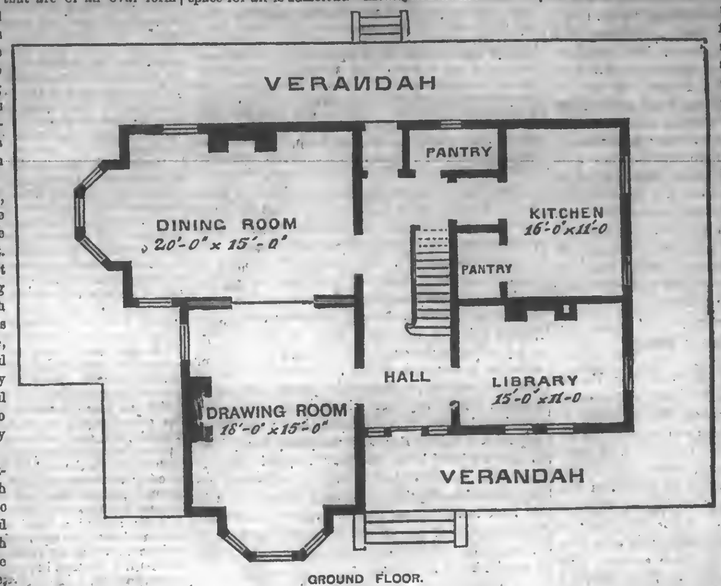
When selecting brushes, see that the handles are not loose, and that the hair does not come out. Brushes are liable to burst loose from the binding when they are bound with cord, unless the cord is well painted. Therefore, whether they are bound with cord or wire, they should have two good coats of paint applied to the binding before they are used.

Before using paint-brushes or whitewash brushes they should be placed with the hair end up and some good varnish poured down against the butt end of the handle, which will spread among the hair and become so hard in few days that the hair and handle will be so firmly united as to prevent the bursting of the brush or shedding of hair. By turning a teaspoonfuls of good varnish into a whitewash brush, and by giving the leather band a good oiling, its durability will be increased sometimes more than one-half.—*N. Y. Times.*

An Out-Door Cellar.

It is very unwise to store a large quantity of vegetables in the cellar of a farm house, even if it is of sufficient capacity. In the latter part of the winter there will be some decay, and nothing can be more detrimental to health than living over a mass of decayed vegetable matter. But few cellars are large enough to hold the products of the farm that requires winter storage. As we devote more attention to the economical feeding of stock, the necessity of good root cellars will be felt more seriously. Carrots, beets, parsnips, cabbage, and the like, require cellar room. A sandy hill-side is the best place for making a cellar, as in this situation good drainage is secured as well as easy access. A good cellar, however, can be made in any place where the water will not be within three or four feet of the surface. Especial pains must be taken to secure good drainage.

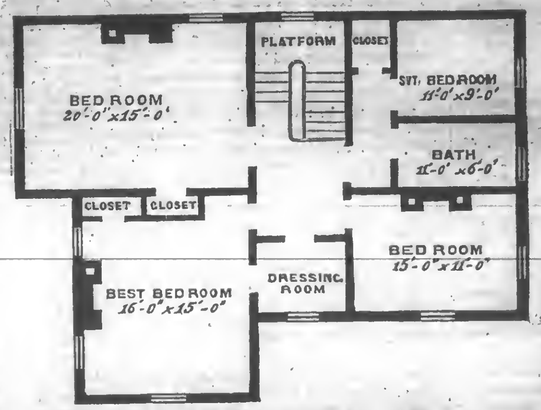
Dig down as far as drainage will allow, and throw the earth back to be used in banking up. If rough stones are to be had, they are the best for the walls; if not, posts and planks will answer. A strong ridge pole is necessary, which must be supported by posts. Bank up the sides with earth, and plank the roof, and cover with straw or leaves, over which rough boards, or something of the kind must be placed to prevent blowing off. An easy entrance should be made at the front by digging down the earth in a gradual slope; and as this part will be exposed to the weather, it should be double; and if of boards, filled between with straw. Where stone is used a space for air is sufficient.—*Michigan Farmer.*



GROUND FLOOR.

Railroad Doors for Barns.

These doors are far superior to the old-fashioned doors, which revolve on hinges. They are opened and closed by means of a rail and several small iron trucks securely attached to the top, and are so constructed as not only to close the door effectually against the ingress of rain, snow and cold air, but to be very durable and in every respect efficient. Large doors are formed by one inch matched boards, placed perpendicularly, and crossed by matched strips of the same in a diagonal direction, or from corner to corner on both sides. These strips are so put on as to represent the sheathing often seen on fine houses, being about six inches in width and covering the entire surface. It will be seen at once that three thicknesses of matched boards, securely nailed and thoroughly pinned, besides being so hung as to obviate effectually all possibility of sagging, as is the case with doors of ordinary construction and workmanship when hung in the usual way, must secure an article of great efficiency and of an almost indestructible character. The labor of opening and closing these doors may be performed by the merest boy, and in windy weather they are not slamming and endangering not only their own fastenings and fixtures, but the lives, also, of all by whom they are approached. The old fashion of placing the trucks at the bottom is anything but desirable, as the former is liable to become clogged by snow and ice; but when it is placed at the top, no obstruction can possibly intervene from this source; the door glides easily along the rail, and never requires to be forced open by main strength. Small doors for tie-ups, sheds, out-houses and other similar buildings, are constructed in a similar way. They are much cheaper than panel doors, to which they are preferable for all purposes where strength and durability are required.—*Cor. Ger. Tel*



CHAMBER FLOOR.

Choice of a Site.—This is a matter of no small importance, and should be well considered before commencing to build. With regard to the prospect, choose the spot for your future residence in dull weather. If pleasant then, it will be charming under a brighter sky. If possible, have at least a few trees ready grown about the place. Let the aspect be south; the level high, but not bleak and exposed. The conveniences for water supply, space for the necessary outbuildings, and ready access to road or other portions of the land, must all be taken into consideration. Look well beforehand. Do not build "in haste and repent at leisure."

The Oddities of Ownership.—Why do people call their residences by such strange names? Why should a brick cottage be called "Stonehenge?" or a little tenement in a shady street "Sunny Side?" Why are bold-looking edifices styled "retreats;" and places without a tree "the elms," "the oaks," or "the willows?" If Jones or Robinson, with the aid of a building society, erect a weather-board dwelling, why christen it "the rosary," "the bower," or "Mannerssutton villa?" Doubtless a lady who takes in boarders may with propriety call her residence "the lodge," out of compliment to her lodgers; but it is decidedly objectionable even for an Englishman to designate his abode a "castle," although the habitation of a Briton may be looked upon as such. A trip round the suburbs will amply illustrate the oddities of ownership, as almost every domicile passed has some queer name.

Stock Department.

Importation of Alderney Cattle.

Mr. Sheldon Stephens, of Montreal, has received advices of the shipment from London of a herd of Alderney cattle for his farm near Montreal. The herd consists of twelve animals—ten heifers and two bulls. Five heifers and one bull were selected by Mr. Henry Tait, Steward of the Home Farm at Windsor, from Her Majesty's herd of Alderneys. The remaining five, with a young bull, were selected by Mr. L. P. Fowler, Little Bushey Farm, Bushey, Herts. The herd before leaving England was much admired, and gave entire satisfaction to Mr. Tait and Mr. Fowler. The animals are described as being perfection in form, and of the best strains procurable. They were shipped on the *Kentiworth*, sailing from London on July 9th, and are expected early this month in Quebec. Mr. Stephens has also purchased some of Prince Albert's breed of pigs from Mr. Tait. We are glad to find Mr. Stephens vieing with his neighbour, Mr. Cochrane, as a breeder of improved stock, and hope the adjacent province of Quebec will yet give Ontario energetic rivalry in this line of things.

Large Merino Fleece.

The sheep department of the *Rural New Yorker*, (Hon. H. S. Randall, Editor,) is ecstatic over an extraordinary scoured merino fleece, the "largest on record," and devotes a column and a quarter to description and eulogy of it and the animal on which it grew. This fleece was one of several which were publicly sheared and weighed at an exhibition conducted by the Ontario and Livingston Counties Wool Growers' Association. It was the growth of eleven months and twenty-one days, grew on a three year-old ram, the weight of whose carcass, after shearing, was only 108 pounds, the fleece weighing twenty-four pounds when taken from the sheep, and nineteen pounds and three ounces after scouring. Mr. Randall says this fleece beats all other known fleeces by nearly, if not quite a pound, while the proportion of carcass and wool makes it still more decisive in superiority. He adds "this case is likely to become historic in the annals of sheep husbandry." The owner of the ram is Levi Noble, Junr., we are not informed of what place.

Cotswold Wool.—Mr. Geo. Jackson, Bloomfield Farm, near Wilmington, Del., writes us that four ewes he imported from Mr. F. W. Stone, Guelph, Canada, last fall, sheared 16 lbs. wool each in May. They are two years old. This is a heavy yield. They have grown very much and are fine animals.—*Co. Gent.*

Stock Purchases.—The Guelph *Mercury* mentions the sale by Mr. Joseph Kirby, of Esquesing, of stock destined for Nova Scotia. Mr. Roy, of King's County, in that Province, bought, of Mr. Kirby recently a Shorthorn bull calf and a heifer calf of the same breed; also a yearling Leicester ram, a Leicester ewe lamb, and a Cotswold ram lamb. Mr. Kirby has also supplied thorough-bred stock to purchasers from Quebec and the United States.

New Disease in Lambs.—The *Gardeners' Chronicle* records the appearance of a mysterious and fatal disease in lambs in one of the eastern counties of England:—"There is a large tract of fine alluvial land in one of our eastern counties, well drained, and lying under a dry climate, where sheep breeding has been followed for many years. The ewes are tupped and lambed upon old pasture, and the lambs suckled—and to a large extent also weaned—upon old pasture, the proportion of clover or two years' seeds being very small. Undoubtedly, lambs were a better business there at one time than they seem to be now. The losses are often excessively heavy, and the flockmasters can scarcely believe some of the hill-countrymen, who boast their large falls of lambs, carried through a summer without any serious difficulty from the all prevalent 'scouring.' Of late years ill-luck has visited particular neighborhoods, with what the shepherds, seeing it for the first time, suppose to be a new malady. Lambs at ten weeks to three months old begin to do badly; their fleeces look dry and 'penny,' and abound with ticks; they 'nab' or bite their wool; they suffer from obstinate diarrhœa; they die suddenly. In their stomachs are found large pellets of wool; in their small intestines are quantities of tape-worms. Last Monday, on a farm well known to us, a lamb died suddenly—so suddenly that it was found with its mouth full of fresh grass just as munched off the sward; the bowels were highly distended with gas; a large clot of wool had passed the first stomach, and the smaller intestines were full of tape-worms. Last year the same farmer lost more than twenty, and a neighbor of his lost more than fifty lambs, affected in this way."

Death of the Short-Horn Bull, "Duke of Bourbon."—We very much regret to learn that Mr. Snell has lost one of his prime bulls in the celebrated "Duke of Bourbon." This noble animal died on the 3rd inst., of Bronchial affection. He was bred by George M. Bedford, of Paris, Kentucky, and imported by Mr. Snell, when eleven months old, at a high price. He was the winner of the first prize at the Bourbon, (Ky.) County Fair as a Bull Calf in 1865, the second prize as a yearling at the Provincial Fair in 1866; the first prize as a two-year-old at the Provincial Fair at Kingston last year, and also the diploma for the best Durham Bull of any age. Besides these important premiums he won six first prizes at County and Township fairs. "Duke of Bourbon" was pretty deeply bred in the "Duchess" blood, and proved a good "getter," impressing his own characteristics in a marked degree upon his offspring. Mr. Snell has used him in his herd three seasons with very great satisfaction. He was a bull of very fine style, combining fineness of bone with sufficient substance, his weight at three years old being 2350 lbs.

An Important Discovery.—A writer in the *Quarterly Review* says that sheep draw from the land on which they graze a considerable quantity of potash, much of which is ultimately excreted from the skin with the sweat. It was pointed out by Chevreul that this peculiar potash compound ("suint") forms no less than one-third of the weight of raw merino wool; while, of ordinary wools, it constitutes about fifteen per cent. of the weight of the fresh fleece. As the "suint" may be extracted by mere immersion in cold water, it is easy for the wool manufacturers to produce more or less concentrated solutions from which the potash may be recovered by appropriate treatment. The development of the new industry is principally due to MM, Maumené and Rogelet, and their process is probably in operation at most of the great seats of the wool manufacture in France. The plan adopted by these gentlemen is a very simple one. They evaporate the solutions which are sent to them until a perfectly dry and somewhat charred residue has been obtained. This is placed in retorts and distilled, very much in the same manner that coal is distilled at gas-works; and the result is, that while much gas is evolved, which can be used for illuminating the factory, and much ammonia is expelled, which can be collected and utilized in many ways, there remains a residue, which chiefly consists of carbonate, sulphate, and chloride of potassium. These three salts are separated by the usual method, and then pass into commerce. Curiously enough, they are remarkably free from soda. The wool manufacturers of Rheims, Elbœuf, and Fourmies annually wash the fleeces of 6,750,000 sheep; and the amount of potash, reckoned as carbonate, which these fleeces would yield, if all subjected to the new process, represents a value of £80,000. But MM. Maumené and Rogelet calculate that there are seven times as many sheep in France as are included in the above estimate; and this will enable us to judge of the enormous loss in potassic constituents which the soil of an agricultural district has to suffer. The practical and very obvious moral supplied by these facts does not yet appear to have penetrated the mind of the British farmer. [Nor that of the Canadian or American farmer, notwithstanding the magnitude and value of the wool interest.—Ed. C. F.]

Veterinary Department.

The Hot Weather and the Health of Stock.

The present scorching hot weather, with the thermometer at ninety degrees in the shade, tells injuriously on the health of all domestic animals. Dogs lie panting, with outstretched tongue, happy if they live beyond the reach of Sir Richard Mayne, his meddling myrmidons, and his vexatious muzzles; like their masters they are averse to much hard work, seeking the cool shade, and enjoying the light drinkable fluids, but certainly less apt to take rabies than in the frigid weather of December or January. Sheep suffer from attacks of flies and from thirst; require as much attention to their water supplies as do cattle and horses; and six months hence will, we fear, in many quarters pine and die from the needful water now withheld.

Horses fully and readily knock up; the direct rays of the powerful sun falling on the head render megrims more frequent than usual; although we might suppose that weather of such Indian splendour would banish all colds and sore throats, we nevertheless find such ailments provokingly common; horses are overheated and exhausted; their skins are highly congested and their nervous energies prostrated, and thus predisposed, if they stand in draughts or are left out in the cold night air, they are just in the condition in which they are apt to catch a host of ailments. Again, from the tear and wear of the bodily structures, typhoid febrile disorders abound; and in badly ventilated, overheated, foul stables, glanders, farcy, and other diseases depending on special organic poisons are rife. Moreover, from the dry hardness of the streets and roads, and the number of loose stones which the heavy traffic is everywhere tearing up on the macadamised ways, horses are very liable to stumble, and we have never known, either in town or country, of such long lists of broken knees. Against such accidents the careful horseman will provide by keeping his horses well up to the mark, avoiding as much as possible heavy or continued work during the heat of the day, and lessening the jar on the legs and feet by having a band of leather or gutta percha nailed on between the bearing surface of the foot and the shoe; pulling up at short stages and allowing the steed a few minutes breathing time and a few swallows of water.

From the continuance of such hot weather the cattle suffer as well as the horses. Not only are the pastures bare and scorched up, and the stock reduced to very moderate rations of "roast meat;" the water supplies are also in many quarters getting short, the water is apt to be turbid and contaminated with organic matter, whilst troublesome flies prevent the poor things feeding or resting. The scarcity of natural food compels the grazier to purchase cakes, beans and other concentrated foods, which, being in such demand, have consequently become very dear. The free use of such food, coupled with the extreme heat, and probably also with a shortness and impurity of the water supply, has in Lincolnshire and elsewhere led to the production of quarter-evil and splenic apoplexy. The dry season, the scarcity of succulent food, and the restlessness of the cows, have diminished the supplies, and increased the price of all dairy produce. From the heat, and the cows galloping restlessly about, their milk is apt to undergo some prejudicial changes, and deranges the bowels of young calves. In some districts, owing apparently to the heat and state of the milk, we have seen cases of typhoid fever among the sucking calves.

In such cases the best arrangement is, if possible, to keep the cows in the house during the day, and only turn them out to graze in the night. The calves when scouring should at first have a dose of castor oil; along with their milk give them lime water. If the bowels still continue irritable, suspend the milk for several days, and feed on well-boiled wheaten flour and linseed gruel; sustain the strength by small doses of gin, whiskey, sweet spirit of nitric or other stimulants, and be particularly careful as to cleanliness. When the calves are attacked by typhoid fever, when the excretion becomes fœtid, the skin acquires a noisome, sickly odour, the belly is tender, and the little animal so weak that he cannot stand, good nursing, tonics and stimulants are the only remedial measures. He had better be removed from the healthy calves; placed in a cool, comfortable pen; have his bed made afresh twice every day; receive, especially when first attacked, occasional small doses of castor oil; twice daily with his food have ten grains of carbolic acid; instead of milk he will generally do better with boiled bread or linseed tea, given often, but in small quantities at a time; several times a day he will be benefited by a little tincture of gentian, ether, or ammonia.—*North British Agriculturist.*

The Dairy.

The Drought and its Influence on the Dairy.

We extract the following from the Utica *Weekly Herald* of the 28th July:—

We have now had several weeks of intensely hot weather, with no rain. Pastures are rapidly failing, and fears are entertained of a severe and long continued drought. We have advices from the western part of the State and from Canada, that the country is suffering from drought, and that the quantity of cheese has already been shortened up materially, and will be much less than last year in these sections. If dry weather continues much longer the amount of cheese made in New York will be very much less than was expected, and it was well understood, even under the most favourable circumstances, that it would be much less than last year. Under this state of things, prices for dairy products must without doubt advance. It will be remembered that cheese has gone off freely, and that there is no surplus in the country. We understand that every pound of the western product is needed west, and that none will reach the seaboard. The cheese made in the Eastern States will be mostly needed in the home markets, and the exports must come from New York and Canada. But a large share of the New York cheese must be kept at home to supply the Southern market and home demand. If we are to have a drought of long continuance, it is easy to see that exports must be cut short. As to the Canada market, it will not be any larger, and probably not so large as last year. We have a letter from a reliable and trustworthy friend, well posted in regard to the Canada product and the quantity on hand, which we give below. It will be seen that the Canada cheese has been already disposed of, while up to September last year it was all held in the factories. The New York cheese, so far, has been moving off at lower rates than the producer can well afford to make it. The question, therefore, for dairymen to decide is, whether under the present prospects an advance in price should not be demanded.

Our Canada correspondent writes from Ingersoll, C. W., under date of July 15, and gives the following:—

"The season to the 1st inst. has been very favourable, both for yield of milk and quality of cheese. We think the make much improved over last. There has been quite a falling off in the number of cows supplying factories, particularly in this section. The few new factories started will not make up for those that have stopped running. From the best information I can get, I think the make will be one-quarter less than last year. Cheese has been sold very freely from 8½c. to 9c. gold; at the latter figure everything that could be got is picked up. Buyers have been very busy the past two weeks, and have cleared out everything in this section fit to move. Mr. Webb, of New York, is, I think, the largest buyer; he has been operating through Mr. Casswell of this place. We have just sold about 700 boxes at 9¼c., the highest price yet paid. This was the only lot remaining unsold in this section. I believe the cheese is bought up all over Canada to the 1st ult. An intense heat and severe drought has prevailed since the 1st inst. The feed is drying up, and milk decreasing much more rapidly than last year. Should the drought continue, it must have a serious effect on the make of cheese. I do not know how far the drought extends, but the heat has extended all over the country."

Milk Fever.

The *North British Agriculturist*, in reply to a correspondent, gives the following directions for the treatment of Milk Fever in cows:—

"Milk fever abounds wherever cows, as in Ayrshire, are bountiful milkers; and great care is requisite to prevent serious attacks. Putting the animals on short commons, as usually recommended—or in popular lingo 'taking a stave out of their bicker'—for a fortnight or three weeks before calving will greatly lessen the number of cases. The reduction must be made alike in the quantity and quality of the food. Dry straw or poor hay is better than rich clover or succulent tares. A dose of physic repeated weekly for three weeks before calving is also a useful precaution; and in all such cases a full dose should further be given immediately after calving, unless, indeed, the animal will drink of its own accord, a bucketful of tepid water, in which a handful of salt has been dissolved. Adherence to a sloppy laxative diet for three days after calving will likewise be essential. The bag should be drawn once or twice daily for at least a fortnight before calving; and for a week after the arrival of the calf great relief will be given by milking four or five times daily. Fully half the cases attacked die—a strong reason for careful attention to preventive measures. Bleeding and a smart dose of physic so soon as the cow goes down is the best that can be done, especially if the patient is fresh. Fomentations along the spine, with the subsequent inrubbing of mustard, are useful. Hot cloths applied over the belly are serviceable in soothing, and also probably in expediting the action of the bowels."

Butter Making at Cheese Factories.

From the address of Dr. N. S. Townshend, delivered before the Ohio Dairymen's Association, we extract the following relative to the profits of butter making and milk condensing at cheese factories.

"If factories make only cheese, some of the valuable constituents of the milk will not be saved or utilized. However much you may desire to retain all the butter in the cheese, its complete retention is not possible, and in spite of your efforts, much will run off with the whey, which although not as good as first-rate butter made from cream, is yet better than much of the cream butter that comes to market; and if properly made it will gladly be purchased at a somewhat reduced price by families with whom economy is an object. Does any one dispute the possibility of making a fine butter of whey? Let me reply by saying that such have a pleasant and profitable lesson yet to learn. Of course the best butter may be largely made in factories whenever the price of butter is relatively higher than that of cheese, or whenever half-milk or skim-milk cheese is in good demand. We do not see why factories cannot, without injury to their reputation, of which they are properly very careful, make large quantities of half-milk and skim-milk cheese of a different form or style from whole-milk cheese, and supply the market with an article at somewhat lower price, much to the comfort and convenience of families that regard the highest price cheese as too expensive a luxury. This would enable factories to make a fine article of butter, and perhaps contribute to improve the butter making of the whole region. The manufacture of butter, whether in factories or private dairies, is not so purely a mechanical operation as some imagine, and therefore the purchase of the last patented churn is not all that is required. The time allowed for the preparation of the cream, the temperature for churning, the making, working and salting, all require great skill, and the perfection of that neatness so indispensable to the manufacture of good cheese.

Condensed milk has not yet been considered one of the common products of our dairies or factories; when it shall become such, one of the commonest objections to our factory system will be obviated, which is, that they do not use the milk for cheese making, either at the beginning or towards the close of the milking season. If our factories would learn the method, acquire the right, and obtain the necessary apparatus for desiccating milk, and adopt the practice earlier or later, then cheese making would be profitable, it would probably prove remunerative to the factories, and a great convenience to their patrons. Condensed or desiccated milk, which is the milk as it comes from the cow after the water is evaporated, with the addition of a trifle of carbonate of soda to prevent souring in the manipulation, and a definite quantity of pure loaf sugar, is the best substitute for fresh new milk that a family can have who do not keep and milk their own cow. During the recent struggle with the rebellion this article was largely supplied to hospitals for the use of our sick and wounded soldiers, and many a poor boy, whose cup of coffee was trimmed with it, could not tell that he had not been treated to cream from his own mother's pantry. In all our large cities, and even in the villages, how much safer and better to feed the babies on milk desiccated to its original consistence than to feed them on the queer compounds sometimes sold as milk. And even if one could always swear by his milkman, and feel assured that he sold nothing that was not milked from his cows, how much inferior the milk from cows fed on brewery grains or distillery slops to that of country cows, whose only feed is the fresh and fragrant herbage of upland pastures.

Curing Rennet.—Orrin Johnson writes the New Hampshire *Farmer's Record* about curing rennets. He says they ought never to be dried inside out. He adds:—"When taken from the calf, put a handful of fine salt into it, lay it aside for a week or more (no salt in the stomach), then stretch them on sticks, —they will not hurt—then stretch them on sticks, not turned inside out. When taken off the stick, see that both ends are tied or closed up tight. Keep a year's stock beforehand. I think one cured in this way worth two dried inside out."

The Apiary.

Industrious and Prolific Colony of Bees.

I have in my apiary one colony of bees in which I feel particular interest—first, from the fact that it has gathered more white clover honey than I have yet had gathered by one colony; 2. It goes to establish an opinion which I have some time cherished, that one great failure in non-swarmers is, there is not room enough for all the colony.

This hive has twenty-seven boxes, of an average capacity of about seven pounds, making an aggregate of nearly 200 pounds.

They now have fourteen boxes completed, except a few cells to cap. They have seven boxes nearly full, five in which they have commenced operations, and but one long empty box. To see one swarm filling the central apartment, and occupying and working in twenty-six boxes, and a few scattering ones gathering in the last remaining box to commence operations, exceeds anything I have ever witnessed before in my apiary.

It will be seen if this prolific queen had been in a hive of only two-thirds the room, with only eighteen boxes, a swarm must have issued from want of room. Seven or eight thousand cubic inches would be required for room for all her progeny.

Is this not one reason for the opinion that the Italians will always swarm? Are not the queens more prolific, requiring more room?

I should be pleased to show this colony, with its labors, to any friend pleased to call and look at it. I think they have now nearly 150 pounds of white clover honey. Jasper Hazen, *in Co. Gentleman.*

Fecundity of the Queen Bee.

In a paper read by Mr. Desborough before the Entomological Society, he makes the following extraordinary statement, to quote from the published report of the meeting:—"The author had succeeded in ascertaining that in certain cases the queen bee will survive and deposit eggs, during not fewer than six seasons, whereas the worker bees only live about eight months. A single queen had produced as many as 108,000 eggs, which would be about 20,000 a year; but the greatest amount of eggs was deposited during the first two years of her life, only about 15,000 being laid during each of the last three years." With regard to the longevity of the queen bee I have little to say, except that I do not believe, as a rule, her existence extends to more than four years. In all my experience I have never known the life of any to exceed that period of time. The workers may and do live about eight months during the late autumn, winter and spring, but on an average, during the summer, their lives do not exceed three or four months.

But it is with respect to Mr. Desborough's statement as to the fecundity of the queen that I must take entire exception. A healthy, vigorous queen, at the head of a strong and prosperous colony, in a well proportioned hive, instead of laying only 108,000 eggs in the course of her life of—according to the author—six years, will lay much nearer 100,000 eggs in one season. I have myself had hives, in which I have been quite certain that the queen has laid at least 70,000 eggs in a single year; and I have had and heard of other hives in which I have no doubt that the numbers far exceeded that amount. I have also had occasion to notice that the fertility of a queen is most abundant in the third season of her life, a great change for the worse taking place in her fourth or last year.

It appears to me most probable that Mr. Desborough has drawn his inferences from observations of a colony domiciled in a glass observatory hive. It must be obvious to every one that bees under such circumstances must be labouring under very great disadvantages; their energies are cramped in every way, and the breeding powers of the queen, as well as the working powers of the ordinary bees, cannot have full scope for their development.—S. Bevan Fox, *in London Farmers' Journal.*

Bee-Swarming Extraordinary.—A correspondent of the London *Free Press* mentions a singular case of bee-swarming that took place on the farm of Mr. Jno. Campbell, Ekfrid. The swarming took place as early as the 15th of March—fully two months before the usual time. Possibly, says the writer, the mild weather induced the emigration from the old hive to a neighbouring apple tree. This could have been no case of swarming. The bees must have left the hive for want of food, or some such cause.

Correspondence

Weather and Crops in Oxford--Hedges, &c.

To the Editor of The Canada Farmer:

Sir—"What short-sighted mortals are we." Allow me to illustrate the truth of the above quotation: In the middle of June last, when I was travelling through the country, the land had been inundated with floods, and everything saturated with constant rain; the growth of crops so luxuriant, (except where the land is low, and undrained) that farmers began to fear for the results. Cattle were in great demand to consume the enormous growth of grass; mowers and reapers were ordered with a recklessness never before witnessed, and harvest hands pre-engaged at very high wages, anticipating such a push and such a drive as is not often seen. Some said grain would never ripe; therefore could not fill—others said we could do without rain till after harvest and nothing suffer from the want of it. Oh! what a change a few weeks' dry weather has made: who could have believed then that in six weeks the earth would be parched, and that great abundance of water would so far disappear as to leave channels dry, and springs fall short of water?—such, however, is the case.

Still, barns are too few and too small to house more than two-thirds of the stuff grown. Hay was never better, either in quantity or quality. Fall wheat yields well to the acre, though not in proportion to the straw. It is shrunken considerably; all but the midge-proof varieties have suffered from the insect pest, some very severely. The barley has ripened too early; it is bright in color, but light in weight; still there will be a large quantity to ship. Early-sown spring wheat has suffered fearfully by the midge—I never saw it worse; in some instances it will not pay for harvesting and threshing. Late-sown will escape its ravages, but will not yield well, on account of the great heat and drought. Oats, for the same reason, cannot be heavy. Potatoes—where shall we find them? I hope some one will save seed to start with again. I have seen but one good field of turnips where sown on raised drills, but several on the flat system, which proves the best three years out of four. Apples are drying up on the trees, especially the Rhode Island Greenings. The blossom was very good everywhere, but the east wind prevented the forming of fruit, and there cannot be many, even of such as they are. The long grass which was rejected in June is quite acceptable now; and to keep up a supply of milk green fodder is used, and some are beginning to feed out hay. A good steady rain would still be valuable in starting pastures and root crops into freshness, but on account of the great scarcity of "hands" dry weather is desirable till the crops are secured; but both we cannot have at one and the same time.

Hedges—I would like to have written at length on this subject; but am waiting till I have visited the farm of Mr. Adamson, deputy-reeve of Durham, who has a fine specimen of hedge from the English hawthorn, capable of resisting any unruly animal, and only eight years planted. I am also glad to learn by your correspondent of Sylvan that he has succeeded in raising a good fence from the common thorn of the country (surely not the hawthorn, if the plants were gathered from the woods). From the appearance of the many hedges I have seen this summer, I am inclined to the opinion that the native thorn is the hardiest and best adapted for our use.

If the buckthorn is an "old favourite" of anybody's, I wish he would tell us how to make it impregnable to colts and calves. I have a great many rods seven or eight years old, which look well and have been well cared for all the time; but I had to erect a board fence along-side of it this summer to keep out cattle from my orchard. Those of my neighbours who have it, have done no better: it will not thicken at the bottom; and its prickles are so slight that a row of thistles make a better *fence*.

R. W. S.

Woodstock, July 27th, 1868.

Note by Ed. C. F.—The above communication was received too late for publication in our last issue.

Poultry Disease.—In reference to a recent communication under this head "Denizen" writes:—"In the Canada Farmer of July 15, W.C., Belleville, says he lost a number of fowls, and describes how they died. In an editorial note at the bottom you say "probably from poison." In this suggestion I agree with you. Near where my fowls are kept fly poison was used, and the fowls that consumed the dead flies are dead also."

Coal Oil for Insects.—A correspondent, over the initials T. B. S., who gives us in addition his full name and address, sends the following communication in reference to the use of coal oil to destroy insects. It seems evident that with some parties the remedy is effectual against insects and innocent in regard to the plants. The difference may be in the kind of oil used. T. B. S. says:—"I was much surprised to see articles in your issues of July 1st and 15th, warning farmers against coal oil as an insect exterminator, and though unaccustomed to writing for the press, I could not forbear giving you my experience in this matter. When the article which you copied from the *Gardener's Monthly* appeared, I had a bed of cabbage plants which were badly infested with flies. As I had not a watering can at hand, my method of testing the recipe was of the most primitive kind. Putting some water in an old tin vessel, and adding to it a little oil, I then took a wisp of straw, thoroughly mixed them together, and sprinkled the plants. In a few days an improvement was visible, after which the process was repeated, completely clearing the plants from their enemies without doing the plants any harm. I used about a tablespoon full of oil to one gallon of water. In these proportions, I am convinced that it will prove a safe and useful application for all the purposes recommended."

The Canada Farmer.

TORONTO, CANADA, AUGUST 15, 1868.

The Weather and Crops.

Since our last issue moderate rains have fallen in most parts of Canada, and some localities have enjoyed copious out-pourings. From a careful examination of a large number of harvest reports that have appeared in local papers in various parts of the Dominion, we are inclined to think that on the whole the crops are not so bad as it was feared they would be, in consequence of the excessive drought. Some places have suffered more than others, and there are favoured neighbourhoods that have not suffered at all. Hay and fall wheat were splendid crops, even where the drought has been the worst, and as more fall wheat than usual has been grown this year, it is fortunate that the season has proved so favourable for it. Of spring wheat we have diverse accounts. In some places it is a failure, in others half a crop, in others an average yield, and in a few cases, excellent. Peas, barley, and oats have, of course, felt the drought severely. So have potatoes. Turnips have borne the dry weather wonderfully, and the recent showers have greatly freshened them up. Should we have abundant rain soon, the bulbs will prove of good size, and the crop turn out as good as usual. We have had a lesson as to the value of summer forage crops for stock, which, it is to be hoped, we shall not soon forget. The pastures have been literally scorched, and only those who have been able to supplement them with cut feed have been able to bring their cattle well through. Fruit prospects are not so good as it was hoped they would be early in the season, owing chiefly to the ravages of insects. The experience of the present summer leads us strongly to urge on farmers, notwithstanding the discouragements of recent years, the expediency of sowing some fall crop, and especially winter wheat, that will be well advanced before drought can affect it.

"Farming for Boys."

Messrs. Ticknor and Fields, of Boston, have recently published a very entertaining book with the above title, written by the author of "Ten Acres Enough," a perusal of which has revived many thoughts we have had on the best means of inspiring boys with a love of life on the farm, and we purpose in this article at once to give some idea of the book in question, and discuss somewhat the general subject to which it relates. The author's object is the very laudable and important one of checking the tendency on the part of young men, born and brought up in the country, to make their way to the city for the purpose of seeking their fortunes, under the impression that agriculture is a dull, prosy, toilsome, and unprofitable occupation, and that comfort and wealth are not to be had in a rural sphere. He aims to show that it is a mistake to leave the green fields of childhood for the dust and turmoil of the city; that rural pursuits give scope for intelligence, are comparatively free from temptation to vice, bring a certain reward to well-directed industry, occasion less anxiety, and are every way favourable to the true advancement of mankind. The lessons which are sought to be conveyed are taught by means of an interesting story, the plot of which is laid on a neglected farm in the State of New Jersey, near the city of Trenton, and having, hard by, direct railroad communication with New York and Philadelphia. This farm is owned and occupied by one Philip Spangler, a sober, hard-working man, but of slovenly habits, ignorant, and wedded to old-time notions of agricultural management. Everything about the place is in disorder, there is no systematic management of farm work, no proper care taken of anything. The buildings, fences, implements, manure-heap, all give evidence of unthriftiness. There are three boys on the farm,—two young Spanglers and a hired or apprenticed orphan lad, named Tony King, whom Mr. Spangler has taken to teach—what he sadly needs to learn himself—how to farm. These boys have a hard life of it, being kept at work without intermission or encouragement, and never having a holiday, except when a rainy day makes out-door work impracticable, and takes Mr. Spangler to the country tavern, not far distant, to learn the news and discuss politics with his neighbours. In course of time, "Uncle Benny," an old gentleman, a distant relation of the Spanglers, takes up his abode at the farm-house. He is in all respects the very opposite of Mr. Spangler, well educated, orderly, prompt, systematic, thoroughly versed in the theory and practice of farming, and withal possessed of a very genial disposition, fond of young people, and anxious to make them happy. This wise and worthy old man soon acquires a great influence over the boys, and gradually wins even upon incorrigible old Spangler. He quickly sets himself at work to improve matters about the farm and farm-house, making a great change in the appearance of things in a very short space of time. He talks to the boys about the right way to farm, lectures in a familiar way about manures, drainage, and a variety of things, until the youngsters become quite enthusiastic and curious. He then, by adroit management, gets Mr. Spangler persuaded to "give the boys a chance," by allowing them to buy a pig and some pigeons, the money for which "Uncle Benny" advances; and also by obtaining two acres of land, which the boys are to work at odd times. The pig they buy is of the Chester County White breed. She brings them ten young porkers, seven of which they manage to raise. They start with several pairs of pigeons. Their land is manured, under "Uncle Benny's" directions, with all the odds and ends, the scrapings and refuse they can find, and planted to corn. A neglected briar patch on the farm, which had become a thicket of blackberries, and from the outer edge of which the family had been in the habit of gathering some fruit each year for domestic use, is

courageously attacked in berry time under "Uncle Benny's" auspices, and an enormous quantity of fruit gathered, enough to bring, when sent to market, *sixty dollars*. The old gentleman sees a mine of wealth in the briar patch, and gets Mr. Spangler's permission to do what he pleases with it. He invests the proceedings of the first blackberry gathering in getting openings cut through the jungle ten feet wide, which are thoroughly ploughed and harrowed, leaving the plot, some six acres in extent, in even rows of bushes. These rows are cultivated and manured. "Uncle Benny" does the planning and financiering, while the boys co-operate with him in the most industrious and persevering manner. Everything prospers under such wise management and diligent labour. Four of the young pigs are taken to the County Fair, where they win the first prize, and sell for ten dollars apiece. The pigeons multiply, and the increase are readily sold. The corn crop is abundant and remunerative. The corn land is planted to strawberries and raspberries, with single plants of sweet corn at such distances as to give a little shade to the strawberries and raspberries, without crowding them, and the sweet corn brings in enough to pay the outlay on the fruit plants. The six acres of blackberries yield four hundred dollars,—two hundred and fifty clear of all expenses. Thus the boys become successful fruit farmers, under "Uncle Benny's" tutelage, grow up to love rural pursuits, become reading, thinking, progressive young men; while old Mr. Spangler yields to the force of the practical logic brought to bear upon him, and improves vastly in his farm management. Comforts thicken and multiply in-doors as the progress goes on out-doors. The upshot of it is, that when a rich uncle of Tony comes along, and wishes to help his nephew make a start in the world, Spangler sells thirty out of his hundred acres, including the briar patch, so that Tony and the Spangler boys become next neighbours, raise fruit on a large scale, get on famously, while "Uncle Benny," when disabled by age, continues to be their "guide, philosopher and friend."

The above is a meagre outline of a well-told tale, which boys will read with as much avidity as the "last new novel," and which cannot fail to rouse them to self-reliance, and a laudable ambition to carve out success for themselves. Of course it is only in certain favoured localities, near large cities, that fruit-farming can be gone into on a large scale profitably; and the author of "Ten Acres Enough" is known to make fruit-farming a hobby; but the narrative we have outlined brings out principles of wider application, although the same brilliant results are not to be looked for in all conceivable circumstances.

It is a most important question—what can be done to interest our young folks in agriculture, as their future occupation? As an old lady, a farmer's wife, lately remarked to us, "The rising generation does not take much to farming." Many reasons may be given for this. But the main thing is to apply the remedy. And must not this be done very much by such means as are suggested by the foregoing narrative? If boys are kept on the farm as mere drudges, if they are made to toil mechanically, instead of being initiated into the whys and wherefores of what they do, if they have no opportunity for making a little money for themselves, if home is not rendered pleasant and attractive, if due provision is not made for occasional recreation, can it be wondered at that they regard the farm as a place of confinement, whence they make their escape whenever they find a chance of so doing? Let fathers act the part of "Uncle Benny" to their sons and daughters, and there would be less complaint of the tendency city-ward, of which we ever and anon hear so much. To sum up, we would suggest as likely means to induce a love of farm life in young people, the following things:—

1. That instruction be given in our country schools on the theory and practice of agriculture, especial pains being taken to explain principles, trace results to their causes, and waken intelligent interest in those natural processes and laws which have to do with successful culture of the soil.

2. That farmers aim to make home life pleasant, by surrounding their dwellings with some show of beauty, providing, as far as possible, in-door comforts, furnishing books and papers for their children to read, especially such as treat on rural pursuits, devising suitable recreations, and avoiding excess of work for young muscles and growing bones.

3. That instead of a constant fault-finding in regard to farm-life, which is too common, agriculturists learn to estimate their calling aright, to feel an honest pride in reference to it, and infuse into the minds of their children similar sentiments.

4. That personal interest be created in farm operations, by giving young people a plot of land, a young animal, a hive of bees, or something of the sort, to encourage and enable them to acquire and save a little money for themselves.

5. That by attendance at agricultural exhibitions, visits to the best conducted farms in the neighbourhood, and the establishment of Farmers' Clubs, at which interesting matters pertaining to rural life may be debated, the minds of young people be sharpened and stimulated toward improvement.

6. In a word, life on the farm, to be attractive, must be elevated and dignified, as it may easily be, so as to render a country home not only as delightful as a city home, but more so, because of those charms which invest nature, and never can be outdone by art.

We anticipate a great change for the better, when the generality of farmers' families are moulded under such influences and principles as those which are brought out in practical action, in the suggestive book for boys which has prompted this article.

Cattle Plague in the West.

An alarming disease has broken out among the cattle in the Western States. The earliest complaint comes from Indiana and Illinois, where the losses are already said to be very great. As the cause of the plague is said to be the importation of Texas cattle, no doubt the track of the plague must be a lengthy one on the plains. Texas droves commenced arriving about the first of May, and as they stopped at many places to graze, the native cattle contracted a disease, which for fatality is said to challenge the rinderpest. Wherever the native stock fed after the departure of the Texas cattle, death ensued usually in about five days.

In one county in Illinois, a writer shows that $10,000 worth of cattle had been skinned in fifteen days at the early outbreak of the pest, and it was spreading with such fearful rapidity that all medicines were abandoned. It chiefly attacked milch cows, and among them not a single instance of recovery was noted. In some communities, the people have been suddenly deprived of milk and butter. Vigilance committees are forming in the interior villages, and threatening to kill every Texas herd that comes within miles of the neighbourhood. At Kankakee, in Illinois, where the disease is raging, an indignation meeting was held, and the owner of a large Texas herd was threatened with its destruction if not removed immediately. The owner assured the committee that removal was then too late to abate the disease, and pacified the people by guaranteeing to make good the loss of all the cattle which should die of the disease in that neighbourhood.

A commission of medical men, appointed by the Pork Packers' Association of Chicago, have visited the points where the Texas disease has appeared, and will issue a carefully prepared report. They state that intense excitement exists in the afflicted localities, and vigilance committees are preventing the landing of cattle from boats or cars, or their passage through the country in droves.

In reference to the question, "what is the disease?" the *Prairie Farmer* of Aug. 6, says:

"We can only answer by giving the opinion of Professor Gamgee, who after a *post mortem* examination of several animals, pronounces it one of a group of inflammatory fevers, or blood diseases, called in England Anthrax Fever, in other places Black Water, from the colour of the urine; and from the resemblance of this one to that, he would suggest that it be called the Black Water of Texas."

The panic has reached Chicago, and the newspapers there say there is no further occasion for secrecy. The dreaded fever found its way into the stock yards, by means of a cow from the infected district, on Monday last, and the cattle dealers and public are in great anxiety. There are in stock yards about 5,000 head of native cattle, and some 4,000 head of Texas stock are herded outside. The fever had begun to spread, and several cases of death occurred in the early part of last week among cattle belonging to residents in the vicinity of the Texas herds. The authorities of Chicago are using every means to prevent butchers from buying any suspicious meat, and a thorough city inspection is demanded to prevent a frightful addition to the mortality list.

The stockyard drovers are offering to sell at ruinous prices, but cannot find eastern buyers. The plague will effectually stop the shipping north of Texas cattle for some time to come, and will perhaps force eastern consumers to other markets than Chicago for a supply. We see by our exchanges already an increasing activity among American buyers in Canada, which may be partially caused by the hesitation to purchase any more cattle from the west until the cattle plague panic subsides. Our Government should take immediate steps to prevent cattle being imported from the Western States into Canada until the pestilence has disappeared.

Food Prospects for the Coming Winter.

It is too early yet to speak very positively of the general yield of grain for the present season. Accordlog to the latest telegrams from Britain, the crop is represented as considerably above an average, both there and generally over Europe. We sincerely hope that such statements may be fully borne out; but there is not as yet sufficient evidence to that effect to set all anxiety on the subject at rest. It is notorious that such a drought, both for length and severity, has not been known in the United Kingdom for a very long time. Even 1826, which gives the nearest approach to it, will have to yield in this respect to the present year. The consequence of this is, that while the harvest has been surprisingly early in a good many places, it has been forced on to the great injury both of grain and straw. In some places the straw has been so short that it could scarcely be harvested; while in many more the grain has been quite scorched, and the hay crop is a failure.

The root crops have also suffered greatly, but only on certain soils. The whole system of husbandry in Britain so very much depends now upon the character of these crops, that any partial failure in them cannot but be widely and severley felt. From such considerations it may, after all, be matter of doubt whether there be such a superabundance in the grain yield as latest reports represent. In our own country it is very manifest that the hopes of a more than usually bountiful crop, generally and very naturally entertained about the beginning of the season, are not destined to be realized. There will be plenty for home use and a fair margin for exportation; but we very much doubt if the cheap loaf is to be among the notable advantages of the coming winter. The midge has been doing its work, and the long drought has also had its influence. Potatoes, we fear, will not now be greatly benefited by the rain, though were it to come immediately, turnips

might still feel the advantage. The crops in the States are on the whole good, so that while the food prospects may not be so bright as at some time they appeared, they are not as bad as they have been represented by some. France is not expected to need almost any importations this year, and the question to be determined is principally how much will meet the wants of Britain.

We can scarcely see that butcher meat can be anything but dear. From the enormous consumption, it can now never be spoken of in Britain as really cheap, and the restrictions lately put upon the importation of foreign cattle, along with the partial failure of the hay and root crops, will not allow the coming season to be much different in the matter of price from those which have gone before.

Tiptree Hall Farm.

The *Mark Lane Express* of July 13th gives a short but interesting account of a visit paid to the above named Farm (Mr. Mechi's), by deputations from the Midland Farmers' Club, the Farringdon Farmers' Club, and the Maidstone Farmers' Club. From the character of the soil of the county and the general healthy appearance of the wheat crops of the district, it was expected that the Tiptree wheat would present a very creditable appearance, but none of the members of the deputation were, we believe, prepared to see so much good wheat for the whole growth as Mr. Mechi showed them. The total extent of land in wheat is seventy-two acres, the farm comprising only 170 acres, of which thirteen are in pasture.

Mr. Mechi having stated at Birmingham that he had made eighteen per cent. on his capital of £16 per acre, and would have preferred to increase his capital to £25 per acre, was requested to give his opinion as to what per-centage he would obtain on this additional capital. Mr. Mechi, in reply, stated that last year he had to sell hay and straw, which, had the additional capital been forthcoming, he should have consumed with cattle, thus obtaining a much greater quantity of manure, both liquid and solid, and thereby increased fertility and yield. He considered, if he had employed £1,500 more, he should have made twenty per cent. on the whole capital:

A discussion then took place which elicited the general opinion, that to farm on the plan pursued at Tiptree was only practicable in connection with security of tenure and compensation to tenant farmers. Mr. Mechi, in conclusion, said that no doubt the main question involving investment of capital in the soil was security of tenure. He was decidedly in favour of a long lease, or an equitable tenant right. Long leases were impossible in all cases, and he thought landlords should be most particular in looking to character, conduct, improving business habits, and capital of tenants, and then bad farming would soon become the exception.

International Convention.

A convention of deputies from a large number of the States, as well as from various Provinces of the Dominion, has lately been held in Portland. The object of this assemblage was to discuss commercial matters in their bearing upon the intercourse between the States and Canada, and especially to consider what might be the most advisable course to be pursued in finding an outlet for the ever-growing products of the Great West. As might have been expected, the question of Reciprocity between the two countries came in for a large amount of attention.

Upwards of two hundred gentlemen were in attendance, and the convention continued its sittings for two days. The speaking was in general very good. Of course it was only what was to be expected that there should be some spread-eagleism, but even of that there was a great deal less than might have been anticipated. The whole affair passed off in the most friendly, satisfactory way. The kindest feelings for Canada and Britain were expressed by the various American speakers, and in the strongest manner everything was deprecated that could in any way interrupt the neighbourly good feeling which ought always to be cherished by the two nations. A series of resolutions was passed favouring a renewal of Reciprocity, and urging measures for the opening up of an International route, by way of the great lakes and the river St. Lawrence, as an outlet for the agricultural products of the two countries.

Parliamentary Documents.

We have to acknowledge receipt of the following publications:

Return to an Address of the Senate, dated 7th May, 1868; For correspondence between the Minister of Agriculture and Immigrant Agents in Canada and Europe, on the probable extent and character of the immigration of 1868; which plainly shows the need of a wiser and more efficient system of promoting an influx of population to this country.

Final Report of the Select Committee on the best means of protecting hemlock timber from destruction; from which it appears that wholesale spoliation of our hemlock forests is going on for export purposes, chiefly in the shape of extract to supply foreign tanneries, but to some extent in the shape of unmanufactured bark. Canadian tanners, with one voice, deprecate this, and ask for governmental interference either in the way of an export duty on bark and extract of bark, or absolute prohibition of exportation.

Report of Select Committee on the Cultivation of the Vine in Canada; a most important document, showing the adaptation of our climate to vine-growing, the excellent quality of Canadian wine, the profitableness of vine culture and wine-making, the disastrous effect of the Inland Revenue Act on the interests of the Canadian Vine Growers' Association, and the duty of our Government in regard to encouraging and fostering this branch of industry.

Fall Show.—The annual Exhibition of the North Riding of Oxford Agricultural Society will be held at Woodstock, on Monday evening and Tuesday, the 5th and 6th days of October next. A very large list of prizes is presented, besides about $250 in special prizes given by the inhabitants of Woodstock.

Substantial Recognition of Services.—An appropriation of $2,000 was made at the last session of the N. Y. Legislature for the benefit of the heirs of the Rev. Chauncey Goodrich, the producer of the Goodrich seedling potatoes. The heirs of Jethro Wood, the inventor of the cast iron plough, have received an appropriation from the Legislature of $2,000, in consideration of the services of their father.

A Good Idea.—The Vernon County (Missouri) Agricultural Society have resolved to substitute agricultural periodicals for diplomas as prizes at their coming fall fair. Foreign and costly journals that would be interesting and suggestive to the class of farmers who are likely to take premiums, might advantageously be put on the prize list, it being certain that they take their own local agricultural paper.

Samples of Grain.—We are glad to find that notwithstanding the severe drought, there seems to be plenty of good grain in the country. Early in the month we saw standing spring wheat of excellent quality, not only with the heads well filled, but to our surprise with straw of fully average length. Many of the farmers we meet with speak of average grain crops, in spite of all the disadvantages of the season. Fall wheat in many instances has been especially good. We have before us excellent samples of more than one variety. The Diehl wheat in this neighbourhood seems to have endured the winter, escaped the midge, and yielded more abundantly than other varieties. Mr. Springer, of Hamilton, as we noticed in our last issue, has raised a good crop of this wheat, and advertises the produce for seed. Mr. James McNair, of Richmond Hill, has a quantity of the same promising grain. The estimated yield of both these parties was over forty bushels to the acre, but the crops were not threshed out at the time we saw the samples. The Messrs. Atkinson, of Etobicoke, after threshing out the produce of two acres of the same variety, obtained one hundred bushels, or fifty bushels to the acre. The quality of all the samples is first class; and we recommend a trial of this winter wheat, especially where the soil is sandy loam, which seems well suited to the crop.

Literary Notices.

Farming for Boys.—Boston: Ticknor and Fields, p.p. 286. We have to acknowledge the receipt of this work from the publishers, and for a more extended notice of it refer our readers to an article which will be found elsewhere in the present issue.

The Little Corporal.—This charming juvenile monthly maintains its high character as a repository of "the good, the true, and the beautiful." An article on the "Wild Flowers of August," which we have copied into our Horticultural department, will give a taste of its quality. Published by Alfred L. Sewell, No. 6 Custom House Place, Chicago, Ill. Price $1, American currency, per annum.

"Sterility is Laid."—A pamphlet of twenty-three pages, containing an address delivered before the Bedford (New Hampshire) farmers' club, Feb. 28, by John A. Riddle, Esq. This address briefly expounds and warmly eulogizes Prof. Ville's new system of agriculture, with which our readers are doubtless familiar, it having been fully explained in the columns of the Canada Farmer.

The Farmer's Gazette and Industrial Index.—This is a new monthly, published at Richmond, Virginia, chiefly in the interest of agriculture, but as its double name denotes, having an eye also to mechanical and other industrial pursuits. Judging from its initial number, it seems likely to be ably conducted. It is, however intensely *Southern*. Having occasion to quote Henry Ward Beecher, it takes care to say "We have no affiliation with him, theological or political." In its "Salutatory," while eschewing party politics, it promises "never to lose sight of the fact that "*the white man must own and govern Virginia*;" and hopes the time is nearer than some think "*when the place that once knew Coffee shall know him no more forever*."

The Prairie Farmer.—We have been rather tardy in noticing the change of form which has recently taken place in this journal, but our delay has not been owing to want of interest in our far-Western contemporary. Its entrance on a new volume at the beginning of last month was made the occasion for altering it from a quarto of sixteen pages to a double quarto of eight pages, very similar in size and general appearance to the *Rural New Yorker*, which journal it now resembles also in combining literary and miscellaneous contents with the agricultural and horticultural. The conductors of the *Prairie Farmer* state that after many years' experience they are convinced that a paper strictly devoted to the farm and garden is not so well suited to farmers and their families as one more general in its character. The new issue is a very handsome-looking sheet, and we doubt not will be conducted with all the ability and tact for which it has been heretofore distinguished.

Analytical and Practical Grammar.—Toronto: Adam Miller, p.p. 240. This is a new treatise on English Grammar, which has been prepared under the sanction of the Council of Public Instruction for the province of Ontario, and forms one of the Canadian series of National School Books. It is on the basis and plan of Bullions' works, but with alterations and additions designed to render it more suitable as a Text Book for general use. The phraseology has been adapted, as far as practicable, to that employed in the authorized Latin Grammar, so as to facilitate the work of the pupil in passing up from the Common to the Grammar School. Exercises in analysis are interspersed throughout the entire work, instead of being confined to a particular portion or section. In the Syntax Department, examples of false syntax are omitted, the editor not approving of that method of instruction. A limited number of examples are inserted in an appendix. We disagree with the editor in his objection to examples of false syntax, and think many more will do the same. An appendix on Prosody has been taken from Dr. Collier's English Grammar, and free use made of the best modern works in this important department of knowledge, so as to render the volume as complete as possible. This grammar is intended for pupils who have mastered the Introductory Grammar already in use in our public schools.

The Canadian Entomologist; No. 1, Toronto, August 1, 1868.

We have much pleasure in acknowledging the receipt of the first number of this little periodical, which is issued by the Entomological Society of Canada, under the editorial management of the Secretary, Rev. C. J. S. Bethune, M. A. It is intended to serve as a medium of intercommunication among Entomologists in Canada, and enable them to tell one another "what they have taken, how and where they have taken it, and what they are in want of;" it is intended also to contain original papers on the classification, description, habits, and general history of Insects, the transactions of the Society, and other matters of interest to those engaged in the study of this branch of Natural History.

The first number opens with a few introductory remarks relating to the objects and scope of the periodical; this is followed by a notice by the Editor of a very remarkable "Luminous Larva," which he describes as appearing in the dark "ringed and dotted with greenish fire," and presenting a singularly beautiful appearance. The next article is entitled "Entomological Notes, Paper No. 1," by Mr. W. Saunders of London. It contains an account, with full descriptions, of the larvæ of several species of butterflies and moths reared by the writer. This valuable branch of entomology, though requiring close attention and unremitting care, and hence commonly neglected by insect collectors, is, we understand, a speciality of Mr. Saunders, and one in which he has obtained much success. This is followed by a short notice of a "New Fluid for Preserving Larvæ, etc.," prepared by Prof. Verrill, and which is expected to prove of great value to naturalists. The report of the annual general meeting of the society recently held in London,—a notice of which has already appeared in the Canada Farmer,—and some lists of specimens for exchange, complete the contents of this number. This periodical, though small and unpretending, will no doubt prove of value to Canadian students of Entomology, and will, we trust, ere long fulfil the hopes of its projectors, and "by and by grow and increase, and acquire goodly dimensions, and become a handsome and valuable exponent of the progress of Entomological science in this Dominion." We beg to commend it to the favourable notice of our readers, and trust that it will be well sustained and supported; while we desire at the same time to congratulate the Society on the enterprize and zeal they have shewn in its publication. The importance of entomological knowledge is becoming every year more manifest, and no class of men are more interested in its progress than farmers.

We may mention that it is issued gratuitously to members of the society, and at the rate of fifty cents per volume to non-members; communications to be addressed to the Rev. C. J. S. Bethune, Credit.

Agricultural Intelligence.

Royal Society's Exhibition at Leicester.

To the Editor of The Canada Farmer:

Sir,—The Royal Show at Leicester has just terminated, and has proved a signal success. In consequence of the cattle disease, no horn cattle were exhibited at Bury St. Edmonds last year, and for the same reason no show at all was held the previous year. Leicester, however, has now amply made compensation for all these drawbacks, and the exhibition just closed, in whatever aspect it may be viewed, is regarded by all with pride and admiration. Although I spent upwards of a week on the trial grounds and in the show yard, I feel myself incompetent to send you a full report of this splendid display of Agricultural, Horticultural and Mechanical skill and industry, and the limits of a single communication will only admit of a very summary view of some of the more salient characteristics. I hope, however, to be able hereafter to use certain portions of the memoranda I have made, for the information of your readers and the improvement of the working of our Societies in Canada.

The grounds selected were most conveniently situated, close to the Town (the race course), and would, had it not been for the severe and protracted drought, have been covered by a thick and elastic sod, a condition so conducive to the comfort both of animals and visitors. Upwards of fifty acres were enclosed by a high boarded fence, so that ample space was provided for the vast and increasing wants of the Society. About five miles of shedding, covered by canvas, forming wide streets in straight lines, were provided for animals and implements. These sheds were of good width, and divided into compartments called stands, of various lengths, hired by exhibitors, in which to arrange and display their different productions; some with only a few articles would occupy a correspondingly small space, while larger exhibitors would require several hundred yards. It will give your readers some idea of the magnitude of the show when I state that in live stock there were 335 exhibitors and 994 entries. In the implement department there were 307 exhibitors and 6352 entries. The catalogue of Agricultural implements and machines, including some other things of a mechanical character, forms a closely printed octavo volume of more than 400 pages. It is, I believe, universally admitted that on no previous occasion have the arrangements in all their multiform details been so perfect; and the result has been a degree of harmony in the working of this huge and peculiarly complicated machine, never before attained in the annals of the Society.

It has been for some years the practice of the English Society to give no premiums for implements and machines without testing them in the field. The kinds of implements for trial this year were those used in the cultivation of the soil; such as steam and horse ploughs, sub-soil ploughs, scarifiers, harrows and rollers. Mowers, reapers, &c., though exhibited in large numbers, received no attention from the judges, but will be subjected to a practical test next year, when they will be eligible for premiums.

This field-testing of implements has now grown into great magnitude, and is a very onerous task. The Society hired a farm for one year from last autumn, nearly two miles from the show ground, at a rent of £1500, for this purpose. As nothing had been done with the land since last harvest, except a slight scarifying of the surface in a few of the fields, the stiffer portions of the farm were as dry and almost as hard as a macadamised road, putting even the steam ploughs and cultivators to the severest practical test. These trials commenced on the 9th inst., and terminated on the 15th. The show yard was opened on the 16th at a fee of five shillings each person, when the judging, which was open, was completed, and the animals and articles obtaining prizes were ticketed. Admittance on the 17th and 18th was half a crown, and notwithstanding vast numbers during these three days entered the grounds, there was no crowding, but every one had the most ample opportunity of examining in detail whatever he desired. The 20th and 21st were shilling days, and notwithstanding the vastly increased number of visitors, the facilities for inspection were not seriously diminished. The attractions were so equally distributed over extensive and well arranged grounds, that overcrowding, for any length of time at least, in particular places, was obviated.

The testing of the steam cultivating apparatus naturally attracted more than ordinary attention. The competition rested between the following firms:—Messrs. J. Fowler & Co, Leeds; Messrs. J. & F. Howard, Bedford; Messrs. Aveling & Porter, Rochester; Messrs. Parker & Sons, Andover; and Mr. G. Hayes, Stony Stratford. The ground being so excessively hard, considerable time was occupied in getting the machines into proper action; the anchors in different parts of the field would be now and then drawn out, and it soon became evident that great power and the strongest machines only would be adequate to the occasion. Fowler's ten horse power double set of hauling apparatus, working their cultivators and harrows, was certainly very effective, as was also a plough moved by a similar amount of power, made by Messrs. Aveling & Porter; which some considered did the best work as a mere plough. Howard's proved itself fully adequate to the occasion, and its operations were watched with much interest and satisfaction. The land on which steam power was brought to bear was in such a condition that horse power in no way could be applied. The prizes offered by the Society for steam cultivation were pretty equally divided between Fowler and Howard, both of whom exhibited and put in motion traction engines of considerable power. The display of steam engines adapted to cultivation, locomotion, threshing, &c., was very large, and comprised specimens of the best workmanship. Steam cultivation in England is no longer an experiment, but has become an every-day fact. As to its general adaptability and profitableness even in this country, more time and data are required before we can reach an absolute conclusion. I heard it stated that the Viceroy of Egypt had awarded a piece of plate, of the value of £200, to Messrs. Fowler & Co., for the strongest steam cultivating apparatus adapted to foreign countries, where serious repairs cannot be readily made. The state of the ground where the horse ploughs were tested was something better than the before-mentioned, but it was painful work to the animals. In this department the Messrs. Howard took the lead, very closely followed by Messrs. Ransome and Sims. Hornsby, Cooke, Bentall, Crosskill, Cambridge, and others whose names I cannot now recall, received either prizes or commendations for ploughs, harrows, rollers, &c. Although there was but little absolute novelty, it was universally admitted that both in quantity and quality the mechanical department this year has far outstripped any preceding exhibition of the Society.

In the live stock department the show fully maintained the high character which the Society has for many years attained. For horses the Royal has never been eminently distinguished. How this is I have not heard satisfactorily explained. The Yorkshire Society in this respect usually excels it. This year 167 horses of all classes were on exhibition, and certainly the beauty and high breeding of most of them gave to this department of the show a large amount of interest and attraction. The blood stallions were pronounced by competent judges to be on the whole of excellent quality, and were judged with special reference to their capability of getting good hunters. Leicester is situated in one of the very best hunting districts of England, and this class of horses is in much request, and have long enjoyed a high character. "Lady Derwent" exhibited at the late Islng-

ton show, where she won the £50 prize and a gold medal, deservedly obtained here the first premium. In symmetry and action she appeared to have reached almost absolute perfection. The cart horses were select, comprising several breeds and crosses, but there were a few weedy specimens that ought, perhaps, not to have been brought forward on such an occasion. The Suffolks, although not large in number, were of very superior quality, and they continue to occupy in England, for agricultural purposes, a high position.

The display of cattle, both as to amount and quality, must be regarded as a remarkable success. The fearful ravages of the plague only so recently arrested, with the present widely extended drought, must have prepared people not to expect too much. Nevertheless, it is very questionable whether this important department was over exceeded on a former occasion. It is true that there was an absence of a few distinguished breeders in several of the classes, but this was quite compensated by others infusing a fresh life into the proceedings. The Shorthorns were, as usual, in great strength. Mr. T. C. Booth, of Warlaby, obtained the first prize of £25 for his four-year old bull, "Commander-in-Chief," a large and symmetrical animal. There was a very fine young bull from Ireland, 14 months old, "Bolivar," that deservedly attracted much attention and won the first prize. The cows and heifers presented many specimens of great size and beauty, and this may also be said of the yearlings. The animals in this and other classes were generally in excellent breeding condition, not so fat, I think, as has been too commonly the case.

The Herefords did not muster strong, only thirty-six entries, but these comprised several animals never, to say the least, previously excelled. The Devons considerably exceeded in number the former, and bore evident marks of high breeding. They were exceedingly pretty, some a little too high perhaps in condition, and evinced a tendency to diminution in size. In the Sussex, a breed very analagous to the Devon, there was an absence of competition; only five animals were exhibited, but these indicated properties of a high order, showing that this breed, confined within narrow limits, deserves more attention than it has hitherto received. The animals attain to a much larger size than the prevalent rule of Devons, make excellent beef, and are said to be unsurpassed in the yoke.

The Alderneys or Jerseys, commonly called Channel Islands, were in great force, and comprised a number of superiorly bred animals. Great improvements have been made of late years in this breed, which is in much request among gentlemen for domestic dairies. I am told it is now just possible, when these animals cease to be useless for the dairy, to make them ripe for the butcher. I did not observe a single specimen of the Ayrshire. There were several excellent specimens of the Norfolk Polled, and a few others of analagous character; also some half dozen Longhorns, of great size and considerable symmetry, but evidently slow feeders. What a striking illustration was here of Bakewell's immortal success with Leicester sheep, and his equally remarkable failure with the Longhorns!

Of the Sheep department, no other words but those of commendation, or rather admiration, would be at all appropriate. The Leicesters appeared not only in large numbers, but with all the improved characteristics of that world-renowned breed. How different do these animals appear to what frequently pass muster in Canada as Leicesters! The Southdowns were perfect beauties, and Mr. Rigden's shearling ram, which gained the first prize of £20, reminded me of an observation made by a distinguished Devon breeder some years ago in reference to the late Mr. Webb's sheep, that "the breeding seemed to be carried to perfection." Lord Walsingham, the Duke of Richmond, Lord Radnor, and others, exhibited animals in this class of extraordinary excellence. The Shropshire Downs appeared to much advantage, and are steadily making their way in several parts of the country; and the same may be said, though perhaps in a somewhat modified degree, of the Oxford Downs, of which there was quite a number of characteristic specimens of the improvements recently effected. The Hampshire Downs, though generally good, were not so numerous as at previous shows; while the Cotswolds, as a class, it was thought, scarcely came fully up to their usual high standard of excellence, although there were several specimens in the yard that certainly had never been surpassed. Mr. Brown's shearling ram, which won the first prize of £20, and others that might be mentioned, were superlatively good. I must not omit to say that though the improved Lincolns did not appear in large numbers, they fully maintained the great reputation they have recently acquired; but they are in general appearance so much like the modern Leicester that ordinary observers scarcely detect any difference.

Several lots of sheep among the different breeds were disqualified on the ground of not being shorn in accordance with the regulations, and other circumstances. This disqualification was extended to pigs in a few instances, their dentition indicating a greater age than that for which they were entered. To expose and prevent frauds of this nature, the Society employs the most vigilant means, as also in relation to the soundness of horses. All animals of which the shadow of a doubt exists, are thoroughly examined by the Society's Veterinary Surgeon, who devotes much time and attention to this important and necessary duty. The display of pigs, both as to number and quality, was quite equal to former occasions, which is saying a good deal. They were classified as small and large black or white breeds, the Berkshire being separate. Other breeds, not included in the above, were put into a miscellaneous class.

Throughout the stock department animals possessing remarkably good points, although failing to obtain prizes, were distinguished by cards having printed thereon in large letters "commended" or "highly commended," a principle recognised through every department of the show. In live stock also the judges placed on the next best animal to the one obtaining the lowest prize, a card printed "reserved number." In case of any one of the prize animals being subsequently found disqualified, the one receiving the "reserved number" would be awarded a prize. This, I was informed, had been found to work well in practice. Another commendable feature of this exhibition arising from the admirable arrangements, is the full opportunities of inspecting whatever one feels a particular interest in. The stalls and spaces are ample, no overcrowding, and the horses and horned cattle, whether they have taken prizes or not, are publicly paraded in the order of their number in their respective classes each day of the show; the public being notified of the hours and other particulars by hand bills, day by day. The carrying out of the details of such an enormous exhibition with so high a degree of precision and dispatch, requires much time to prepare the regulations, and a large outlay of money, patience and perseverance in their practical application. We should do well in Canada to keep the example of the English Society steadily in view, and follow it as far as circumstances will render practicable.

During the show, I had the pleasure of accidentally meeting two Canadians, Mr. John Miller, of Ontario, and Mr. Simon Beattie, of Quebec; others may have been present, but I had not the good fortune to fall in with them. These gentlemen were in quest of breeding stock suitable to Canada, and I parted with them attempting to negociate for a shearling Cotswold ram, the asking price of which was one hundred guineas! First class animals are held in England at enormously high rates.

The Royal Horticultural Society of London, held for the first time last year a country exhibition at Bury St. Edmunds, at the same time and place as the Royal Agricultural Show; and the success which attended the experiment induced the Horticultural to do the same this year at Leicester. Several acres of the ground adjoining the Agricultural show yard were fenced in, and extensive shedding and tents were erected for the exhibition of fruits, vegetables and flowers. The arrangements, like those of its twin sister, were most ample and complete, and the whole display had a beautiful and artistic effect. Many of the choicest exotics from London and the gardens of the nobility and gentry of the midland counties graced the scene, which was on the whole of unrivaled magnificence. In such a season of drought, I could hardly believe my senses that such splendid specimens in the various departments of horticulture could be produced. It is truly pleasing to see these two great national societies working together in harmony but independently, and both in this instance with the most gratifying and successful results.

Speaking of horticulture, I may just mention that while strolling one evening along the banks of the Soar, immediately close to Leicester, I was induced to enter the precints of what once was a magnificent Abbey—founded in the 11th century. The outer walls are in excellent condition, enclosing a space of forty acres, now used as a nursery. There are some fifty acres devoted to the same purpose outside the walls, and the manner in which these beautiful and hallowed grounds are kept, and the healthy, growing state of their productions, reflect great credit on the taste and skill of their enterprising proprietor. It was here that Cardinal Wolsey, in troublous times, while on his way to London, took refuge and died, and his ashes repose beneath the fragrance and beauty of trees and flowers. What remains of the ruins of the Abbey proper are clustered with ivy and other creepers to the very top, while the extensive old walls are covered by the choicest varieties of fruit trees. What lessons does such a scene teach! I could not help thinking that if the disembodied spirits of those whose feet centuries since trod this sacred enclosure, were cognisant of what is now doing in this lower world, they would not regard the gardener's operations, at least, as a desecration; for the Monks, despite the abuse which it has been too much the fashion to heap upon their memory, were in their day not only the great conservators of sacred and clerical learning, but foremost in the improvement of agriculture, gardening, and the useful arts of life; the testimony of which is so frequently present in these British isles.

The drought still continues in almost unmitigated intensity, though heavy rains have recently fallen in some parts. Last Saturday the first shower fell, worthy of the name, that I have seen since my arrival in England. Harvest operations are now become general, and wheat is the only good crop which the farmer will this year gather. The harvest is full three weeks earlier than the average of seasons. I have not heard the amount taken at Leicester for admissions to the show, but it will prove, no doubt, unprecedentedly large. I am now on my way to the Highland Society's show at Aberdeen.

GEO. BUCKLAND.

Shrewsbury, July 22, 1868.

Imports and Prices of Wool.

The *Economist* (New York) states that the imports of foreign wool at New York for the first half of the calender year are only about half the quantity and value of those for the same period of last year. "For the first six months of 1867 we imported 13,000,000 lbs. valued at $2,233,000, against 6,700,000 lbs. this year (1868), valued at $1,105,000. The decrease has been principally in the arrivals from England, the Argentine Republic and Mexico, while those from Russia have been doubled. The abundance of the home crop, especially in California and Texas, has limited our wants for foreign descriptions." The leading item in the table given for 1868 is the Russian wool imported, amounting to 3,122,013 lbs., of the value, as entered, of $570,765.

The *Economist* also adds the following statement of the current value of domestic wools, as compared with that of two years ago—before the passage of the present tariff:

	June 10, 1868.	July 6, 1866.
Am. Sax'y fleece, per lb...	60@65c.	50@55c.
Do. full blood Merino....	52@56	50@57
Do. ¾ and ¾ Merino...	46@50	45@50
Extra, pulled.....	42@40	55@60
Superfine, pulled.....	42@48	47@53
No. 1, pulled.....	30@36	38@45
California fine, unwashed.	28@32	33@38
Do. common, do....	22@25	20@25

A subject for the Chamber of Agriculture.—According to *The Coventry Standard*, "a landlord in Mid-Warwickshire refuses to let his tenants use mowing machines, lest they should injure the game!"

☞ During last year over half-a-million of money—£540,884—was transmitted to Ireland from America by omigrants to their friends—£202,914 of the sum being in the form of prepaid passage orders.

Grapes along the Lake Shore.—M. B. B. writes the *Ohio Farmer* that grape prospects all along the Lake Shore region continue very good, though considerable damage was done to the vines around Sandusky by the storms last month. The dry, warm weather for some time past has been favorable to the growth of the vines and fruit. It is added that the prospects for peaches and apples in Lake and Ashtabula Counties are quite fair.

Abolition of Toll-Gates.—The Perth County Council, at its late sitting, adopted a report of a committee recommending the throwing open of the toll-gates on all the public roads in the county. The ground taken for this movement is, that it will be much better to build and keep in repair the public roads in the county directly by public funds, and thus save the expense of keeping up gate houses, and paying the salaries of gate keepers—each gate costing probably from $300 to $400 for keeper's salary, and building and repairing houses. The *Free Press* hopes the Middlesex County Council will adopt a similar course, which would result in a saving to the tax-payers of that county of not less than $50,000 a year.

Cloth Manufacturing in Australia.—Manufactures in Australia are gathering strength. A woollen company, which has gone recently into operation, has now nearly 5,000 yards of cloth made, comprising the kinds called "tweeds," "meltons," "diagonals," "stripes," "hair lines," &c. These cloths have not yet been sent into the market, as the company intend to accumulate 5,000 yards, for the production of which a premium of £1,500 was offered by the Government some time since, and claim the money, before they appeal to the cloth-consuming public for support. The finished products of the factory are of many different patterns, serviceable and lasting, as they consist wholly of good sound wool. With its present resources, the mill will turn out, when at full work, about 1,500 yards of cloth a week, and consume 1,820 lbs. of washed, or 2,880 lbs. of greasy wool.

The Muskoka District.—The Orillia *Expositor* thinks its Muskoka friends have taken an excellent plan to bring the capabilities of the District under the notice of settlers. They will issue, in a week or two, a pamphlet showing fairly the advantages possessed by the Territory, and also its drawbacks; and as quite a number of these are to be scattered throughout this Province and the old country, we may expect a large influx of settlers to the district during the coming fall in consequence. The resources of the district only require to be more generally known to have all the good land it contains taken up. The pamphlet is being printed for the "Muskoka District Settlers' Association," which has already done much to advance the interests of Muskoka, and remove the erroneous impressions which have been made on the minds of the people of many parts of the Province by the false statements of those who have had only a glance, and perhaps not even a glance, at a small portion of it, and then reported they "have been in Muskoka, and found no good land worth mentioning—nothing but rocks!" Parties wishing for reliable information concerning the District should adress the courteous Secretary of the Association, J. B. Browning, Esq., Bracebridge, who will be always found willing to reply to their enquiries. Pamphlets forwarded to any address on application to the Secretary.

Close of the St. Thomas Flax Mills.—The operations which were carried on in this town for several years have been brought to a close, and in common with many others in the country, the St. Thomas mill is lying idle. This is owing to several causes, but chiefly to the decline in the price of cotton. During the American war, when the supply of raw cotton was difficult to obtain, and English factories were turning out scarcely half the quantity of previous years, the manufacture of flax was found remunerative, and in this country several enterprising firms were found to engage in it. Foremost of these were the Messrs. Perrine, who at one time, we believe, had not less than twelve mills in various parts of the province. In connection with Mr. Alexander Young they began operations here about four years ago, and being well patronized by the farmers of the district, who entered heartily into the culture of the flax crop, they had the prospects of establishing an excellent business. The farmers, finding the crop a paying one, were eager to continue it, and were ready to supply whatever quantity was needed. The decline of prices in the manufactured article, however, made it imperative on the part of the millowners to close the business, and thus a valuable and very important branch of industry, not only to the neighbourhood but to the country, is brought to an end. During the four years the mill was in operation here, the money paid out in the purchase of raw material and running expenses ranged from $10,000 to $25,000 yearly—giving employment to thirty men and as many boys in the fall, and upwards of twenty hands the rest of the year—*St. Thomas Journal.*

The Raspberry in Quebec.

To the Editor of The Canada Farmer:

Sm,—Several communications I have lately seen respecting the alleged want of hardiness in the raspberry, induce me, with your permission, to venture a few words of encouragement to any who may be hesitating as to the possibility of their cultivating in Canada the finer varieties of this delicious fruit. To such, then, I would say, it is not because you are located far to the north that you will not succeed. On the contrary, living near the City of Quebec, I never fail to have a most beautiful crop. Last winter was the most severe experienced here for many years, the thermometer sinking to 37° below zero, and remaining near about there for days together. It has been followed by a most scorchingly hot, dry summer, yet my bushes are fairly loaded down with large and delicious fruit, and not of the common kinds, but of the, so called, tender Antwerps. From my experience with this berry, I have thought that it cannot be merely the cold which injures them, but, possibly, rather the alternate freezing and thawing which they are exposed to in milder countries. I have cultivated here yellow Antwerps for the last fifteen years without experiencing any difficulty; and six years ago, wishing to try other varieties, I procured a few bushes of "Red Antwerp," "Franconia," "Falstoff" and "Victoria." They have all flourished; but the Red Antwerps produce so much the best and largest fruit, that to me the others are valueless.

My mode of cultivation is simply this:—About the middle of September, select a spot where a goodly supply of snow is sure to lodge early in the fall (no difficult matter here), manure the ground heavily by digging in decayed stable manure, plant in rows about three feet apart, plants about eighteen inches asunder in the row, and shortly before the first fall of snow, throw over them any refuse straw or branches. We find potato stalks and spruce boughs excellent. These will gradually bend the plants towards the ground, the weight of the snow will assist, and in the spring they will come out ready to send a leaf from every bud. I had omitted to say that, after planting, I shorten the canes to within less than a foot of the ground. Succeeding springs, I merely take off a few inches from the tops. The Red Antwerps, with me, average from five to six feet high. We train them to horizontal strips of board, placed between each second row, on stakes about three feet high, bringing two rows to meet to one board, and leaving thus an alley between each second row. I find it essential to tie them up in this way, as, if not done, the weight of the fruit brings them flat to the earth, soiling and spoiling the berries. We top-dress well with decayed stable manure and ashes every spring, and again as soon as the fruit is gathered. Treated this way, a very small patch will supply a very large family, and will last without replanting or changing the location for an indefinite number of years. Even without any covering except the snow, very good crops can generally be had; but a few branches or potato stalks cost very little trouble, and insure a large yield, and by bringing the canes evenly and gradually to the ground, prevent their being broken.

As I said, I have yet found no variety to equal the Red Antwerp; but Mr. Beadle's letter, in your last number, has given me an inclination to try what could be done here with the "Hornet," for, so far, I have had no necessity to look for the *hardiest*, but simply for the *best* and *largest* raspberry. As to productiveness, they all produce about as many berries as you could by any possibility stick on the bushes.

F. W. A.

Quebec, Aug. 6th, 1868.

Wild Flowers of August.

BY MARY LORIMER.

It is now August; sultry, midsummer August. There are not as many flowers to be found as in the earlier months. The waxen May-flowers, and frail Anemones, and many delicate vernal blossoms have folded themselves away to sleep till next spring. But there are many beautiful flowers in August. I hope my young friends have found and faithfully pressed many a wild flower, and have become so in love with the charming and healthful pursuit as never to give it up.

In July I found forty-five wild flowers, and I hope you found several, and that among them were the six varieties of the pretty Silk Weed, or Milk Weed. The species called Tuberosa is the most brilliant orange, and the Quadrifolia is remarkably pretty, with balls of pale, pink flowers.

You must find in August the handsome Orchis family. The white orchis is lovely, and the Purple Fringed Orchis is superb, with its elegant, fragrant blossoms.

The Wild Lilies are a gorgeous family, from the fiery red, single lily, growing so freely in the woods, to the graceful buff yellow, where twenty delicate bells often tremble upon one stalk.

The yellow and purple Gerardias are found in August; these you can never transplant with any success, because they are what is called parasitic plants, and so is the Scarlet Tipped Painted Cup. Of these parasitic plants I must tell you at some other time, and also of the beautiful air plants, which grow and blossom on a stick of wood, or piece of cork; and require no earth.

Do find the rosy-purple Rhexia or Meadow Beauty, and the flower of Parnassus, the large, white petals, veined with delicate green lines. Above all, look sharp for the superb Cardinal flower, that marvel of brilliant carmine color, though you will not have to look very sharp, for you can see it from afar. It seems to light up the damp nooks by the brooksides, where it loves to grow.

The ferns, too, are beautiful in August, and the trees are full of interest; every tree having its own peculiar way of growing. How wonderful this is; a Maple spray will never grow like an elm spray; each knows whether the leaves must come out opposite on the branches, or alternate, and they never make a mistake.—*Little Corporal.*

Horticultural Single-Tree.—Our correspondent, D. B. Weir, of Lacon, Ill., has furnished us with one of his new whiffle-trees, made expressly for working among young fruit trees, orchards, &c., which we find accomplishes the intended object in as perfect a manner as anything of the kind we ever had the pleasure of thoroughly testing. The leather traces are let out in length a few inches, so as to pass around the end of the implement and hook in the rear. They are secured in their position, so as to extend beyond the ends, and to render it impossible for anything but the leather to touch the tree. We have used it both with a single horse, and with a double team in full ploughing. We requested our ploughman to see if he could not rub off some of the bark of the trees, but he asserted it to be impossible, exclaiming, in his own vernacular, "This is the biggest thing out!"

In cultivating orchards of many hundred standard pear trees—the rows being planted nearer one way

than the other—we had previously found it impossible to run much nearer than two feet to the rows, leaving a strip nearly four feet wide unploughed. This was afterwards finished, with a good deal of difficulty, by the use of a single horse. Now, by the use of Wier's Single-tree, placed on the right or left of the evener, according to the direction of the furrow, whether from or to the trees, the whole work may be neatly accomplished at one operation. If the trees are near together, it will be most convenient to finish with the one-horse plough. As the new single-tree is short and light, it is necessary to have another equally light to balance it, when using it with two horses. We think that all orchardists, who desire to keep their grounds in a neat and finished condition, without resorting to hoeing or spading in the rows, will be gratified in procuring this new contrivance. —*Country Gentleman.*

A New Mulch for Grapes.—A correspondent of the *Country Gentleman* speaks very highly of leached ashes and cut grass as a mulch for grapes. First mellow the soil; spread the grass several inches thick; sprinkle with water, and apply the ashes. Grapes thus treated have grown luxuriantly all through the recent drought.

Quick Growth.—"The new early peas, 'Ringleader,' sown on the 12th of February, were this week harvested, fully ripe, at Messrs. Sutton's farm, London Road, Reading." So says the *Mark Lane Express* of July 1st. This would be deemed terribly slow growth here, and may illustrate the difference between the British and Canadian climates.

Entomology.

Exhibition of Insects at Paris.

An exhibition of a novel and interesting character is to be held during the present month in the Palais de l'Industrie, at Paris. It is to be confined entirely to Insects in their practical relation to Arts and Agriculture, and is intended to include the illustration of the propagation of useful insects, methods of curing or preventing disease, and economical management, and the history of destructive insects, with means of counteracting their ravages. Noxious insects are to be classified according to the plant on which they feed, and not according to their scientific order. The exhibition is to open on the 1st and close on the 31st of August, and is under the management of Dr. Boisduval, M. Guerin-Menoville, and other entomologists and scientific agriculturists. The following are the principal heads of classification:—First division—Useful Insects. 1st class.—Silk-producing insects. 2nd class,—Insects producing honey and wax. 3rd class,—Insects used in dyeing and for colour. 4th class,—Edible insects, crustacea and mollusks. 5th class,—Insects employed for medical use. 6th class,—Insects used as ornaments. 2nd division,—Destructive insects. Ten classes, comprising those that attack cereals, the vine, plants used in industry, forage, vegetable and ornamental plants, fruit trees, forest trees, timber used for building, truffles and fungi, dry organic matters, and, lastly, parasites of man and domestic animals. The third division comprises three classes, carnivorous and parasitic insects—those that destroy chrysalids and insectivorous animals, birds and reptiles. Fourth division,—Insects and other animals destructive of mollusks, and notices respecting edible snails (!) and the benefit that cultivators may derive from them. Fifth division,—Optical instruments for entomological purposes, and special apparatus connected with the rearing or destruction of insects. Printed or written memoirs are also to be admitted, even without specimens of the insects to which they refer. It is also intended that there shall be conferences during the exhibition on various subjects connected with entomology. Such an exhibition, if well carried out, must surely be productive of great benefit to the agricultural interests of France, and might well be imitated elsewhere.

Specimens reared from Larvæ or Pupæ.

From time to time we have endeavoured to rear specimens that have been sent to us, in order to discover what their perfect state is like, and thus learn their name and whole history. To obtain satisfactory results is by no means an easy matter, as a day's neglect will often prove fatal to the caterpillar, and this, from want of proper food, or absence from home, cannot always be avoided; some, too, dry up during the winter, and never emerge from their pupa state; and others are destroyed by parasites. The following is a brief account of our limited success:—

Strawberry Worms.—In last year's volume (C. F. Aug. 1, 1867, p. 238; do. Oct. 15, p. 311) we referred to some specimens found feeding on strawberry-leaves, and sent to us by Mr. Arnold, of Paris, Ont.; these we have entirely failed in rearing, much to our disppointment.

Fall Web-worm on Apple Trees.—Last year we received some caterpillars from a correspondent at Halloway, County of Hastings, which we stated were specimens of this insect; these we fed for some time, till at length they turned into the pupa state, enclosing themselves in a slight hairy cocoon. On the 20th of June, 1868, a moth emerged from one of these cocoons, and during the following week many more came out; they were all, as we expected, specimens of the Fall web-worm (*Hyphantria textor*, Harris) and were the first that we had ever seen. We also raised some specimens of the same insect from caterpillars infesting our own trees. Last year we stated that "they have not, that we are aware, been before recorded as occurring in this country;" we have lately been informed by Mr. Saunders and Mr. Reed, of London, Ont., that they have known and reared the insect during two or three years past, though they never recorded its occurrence. During the last few days we have noticed the webs of this insect upon our apple trees, this being the time of year when they first make their appearance; we would strongly recommend our readers to look over their orchards and cut off and destroy any of the webs of these destructive creatures that they may find.

Balsam-fir Saw fly.—The correspondent mentioned above also sent us some cocoons of the larvæ that he found injuring his Balsam-fir trees (C. F. Aug. 1, 1867, p. 238; do. Sep. 2, p. 269). From these only one solitary specimen has come out; it is a black-bodied saw fly with beautiful iridescent wings, but we have not yet determined its name.

Promethea Emperor Moth.—In our issue of the 15th of June of the current year (page 172), we noticed the receipt of two singular cocoons from a lady at Mimico, and we gave an illustration of the large moths we expected them to produce. About ten days after the publication of our notice, two handsome female Promethea moths emerged from the cocoons, similar to the lower figure in our illustration; they now form fine additions to our collection.

The Wheat Midge.—In June last we received a lump of clay filled with orange larvæ from Mr. Belch, of the *St. Mary's Argus*, and in our issue of the 1st of July we published Mr. Belch's letter, with the result of our examination of the specimens, stating our belief that they were the larvæ of the wheat-midge. During the succeeding fortnight an immense number of the winged midge emerged from the clay, and, being unable to escape through the gauze lid of the box in which they were enclosed, almost covered the surface of the clay with their dead bodies. We hope to hear what effect they had upon the crops in the neighbourhood from which our specimens were brought, but we fear that the account will not be a very cheering one.

The Privet Sphinx Caterpillar.—In our last issue we noticed the receipt of one of these caterpillars, and stated that, to our surprise, it had gone thus early into the chrysalis state, from which we did not expect it to emerge till next year. To add to our surprise, on the evening of the 8th of August, we heard something flying up and down our study, which, at first, we took to be a bat, but as the noise of its wings was "wish-a-wish-a-wish" instead of the "flitter-flutter" of a bat, we knocked it down, and found it to be a fine moth (*sphinx cinerea*) which had come out of the above mentioned cocoon.

Chad Fly.—We have received, but not in time for more than this acknowledgement, a communication from Mr. Tait, of Boverley, accompanied by a specimen of a singular and "ferocious" looking insect. It is the Chad Fly. We have placed the specimen in the hands of our artist, and hope to give an illustration and some account of the species in our next issue

The Household.

Drowning.

In a recent number of this journal we gave a few "hints for emergencies." We propose occasionally, without repeating the heading, to add such suggestions as may appear useful and seasonable, as a guide to the inexperienced. Among the most serious accidents, in connection with which any of us may be suddenly called upon to render aid, there is one that has become recently very frequent, and in which assistance is too often speedily unavailing—the accident of drowning—an instance of which is recorded in nearly every newspaper that we open.

In these melancholy catastrophes, unless the unfortunate individual is quickly rescued from his peril, there is very little hope of restoring animation. A few minutes' complete submersion under water is sufficient to extinguish life. And yet, as we every now and then hear of well attested instances of resuscitation after a comparatively long submersion, it is well, when there is any ground for hope at all, to use every means in our power to recover the drowned. One chief reason of the discrepancy of statement that we have met with in regard to the length of time that a person may be submerged and yet recover, is owing to the different modes of death in drowning. In some instances the person faints almost immediately on the occurrence of the accident; and in these cases animation may be suspended for a much longer period, without proving fatal, than when no such arrest is given to the full activity of the vital functions, and suffocation, neither modified nor complicated, is the cause of death. The appearance of the face will often indicate whether fainting occurred or not. In some drowned persons the countenance is remarkably pale, in others it is livid and swelled. The first would most probably be the result of syncope or fainting, and would leave more hope of recovery than the latter appearance. Still, after five minutes of complete and uninterrupted submersion, very little expectation could be entertained of restoring the breathing and animation.

In the treatment of drowned persons, the greatest gentleness and care should be observed. It is a common opinion that the lungs are filled with water, which is the chief cause of suffocation, whereas usually very little water enters the lungs, the spasmodic effort caused by the contact of water with the glottis preventing the entrance of fluid into the windpipe. Nothing is more foolish, therefore, or more likely to do harm, than the practice of holding the drowned person up by the heels, or with the head in any way low, or rolling the body about, or any other of the rough usages resorted to, with a view of emptying the lungs of water. There are three principal objects to be kept in view in our treatment of the drowned. First, to restore the breathing—Second, to restore or keep up the animal heat—and Third, to rouse dormant animation by stimulants.

The two first objects should, as far as practicable, be attended to immediately; the wet clothes removed, and dry blankets or dry coats substituted; but no time should be lost in the first and most essential part of the treatment, namely, efforts to restore the breathing. First try the following plan. Place the patient on the ground with the face downward, and one of the arms under the forehead, in which position the tongue will fall forward, so as not to obstruct the entrance of air, and fluid from the mouth and throat will naturally escape. If breathing does not immediately commence, move the body on the side, a little over towards the back, apply hartshorn, snuff, or tickle the throat with a feather, and dash a little cold water on the face. If these measures have no effect, replace the patient in the former position, with the face downwards, supporting the chest upon a folded coat or other garment. Then turn the body back again gently on the side, and a little beyond. Repeat these movements carefully and perseveringly, about fifteen times in a minute, or once in every four or five seconds. The reason for these movements is, that the first or prone position forces the breath out of the body, the weight of the body being on the chest; this weight is removed by turning the body on the side, and air will naturally tend to enter the chest. The effect is increased by making uniform and brisk pressure with the hands on the back, between and just below the shoulder blades, while the body is placed face downwards, removing the pressure completely or turning the body over on the side. One person during the whole time should gently support the head, and keep the arm under it when the face is turned down.

Another method which may be resorted to, if the preceding measures do not in the course of five minutes seem to have any effect, is that recommended by Dr. Sylvester. Place the patient on the back, with the head higher than the feet, and support the head and shoulders on some kind of cushion or pad. Draw forward the tongue and keep it projecting beyond the lips. Remove all tight clothing from about the neck and chest, not omitting the braces. Then placing yourself at the patient's head, grasp the arms just above the elbows, and draw them gently and steadily upwards above the head, and keep them thus stretched up for two seconds. This is done to draw air into the lungs. Then turn down the patient's arms, and press them gently and firmly against the sides for two seconds, to force out the air. Steadily repeat these movements, alternately, about as often as those recommended previously, namely, fifteen times in a minute. As soon as any spontaneous breathing is induced, let these efforts be at once discontinued, and proceed to keep up the warmth of the body.

Should the foregoing measures seem unavailing, attempts may be made to restore the breathing by insufflation of the lungs with a pair of bellows. The nozzle of this is to be inserted into one nostril, the other nostril and the mouth being closed. The projecting cartilage of the throat is also to be pressed back while air is introduced. To expel the air, pressure is made with the hand on the chest and abdomen. These movements should be repeated as before, with about the frequency of natural breathing. The treatment should be persevered in for several hours if necessary.

At all times it should be remembered that the free access of pure air is indispensable, and all unnecessary crowding round the patient should be avoided. To promote warmth, wrapping the body in warm blankets, friction with dry and warm flannels, the application of bags of hot salt, bran, or the like, are the readiest means to be resorted to.

As soon as respiration is sufficiently restored, small quantities of wine, brandy and water, or warm coffee, may be carefully administered.

Washing Windows.

A correspondent of the *American Agriculturist* gives the following improved mode of washing windows, which, although not wholly new, may be valuable to many of our readers:

"The nicest article for washing windows is deer skin, as no particles come off to adhere to the glass and make it look as if washed with feathers. There is no need of anything larger than a hand basin for washing windows. The great splashing some people make in the exercise of their art is entirely useless, and is, moreover, deleterious. When the water is permitted to run down in great quantities upon the glass, it dissolves the putty and soon loosens the panes from their setting, and also stains the glass. Two pieces of nice wash leather and a bowl of suds are all that are necessary. Wipe the glass first with the wet cloth or leather, and after it has become dry rub it with the clean cloth and it will look clear, and far more so than if rinsed with a dozen pails of water."

☞ In a class of little girls in one of the schools of Boston, the question was asked, "What is a fort?" "A place to put men in," was the ready answer. "What is a fortress, then?" asked the teacher. This seemed a puzzler, until one little girl of eight summers answered, "A place to put the women."

Poultry Yard.

Chickens Dying in the Shell.

Everybody does not keep poultry, everybody will not, but many people do. We are beset with letters asking why chickens die in the shell instead of emerging from it; why hens do not bring their chickens off punctually. We answer all their questions with another: Do you moisten your eggs yet? If you do not, there is the cure for all your troubles, the solution of all your difficulties.

Partridges, Pheasants, and Grouse seem to be more successful at hatching than our domestic fowls that have all known "means and appliances" to boot. The truth is, their eggs are thoroughly wetted twice every day. At morning and evening the hens leave their eggs to feed; they go in among the damp grass covered with dew, and come back wetted through, especially on the breast that is immediately in contact with the eggs. The hen does not even shake herself before she sits on them. Every egg is well soaked, and the moisture penetrating to the membrane lining the inside of the shell keeps it soft; whereas, especially in this dry and hot weather, if the hen is merely taken off her eggs for half an hour, and they are not moistened, the membrane becomes as dark and tough as india-rubber. The chickens cannot get out. For a full week before hatching time, when the hen leaves her eggs, dip your hand in water, withdraw it while streaming, and wring it over the eggs.—*Journal of Horticulture.*

Imported Eggs.—For the encouragement of those who contemplate importing eggs from England for the purpose of hatching, we are able to state that a gentleman in Montreal obtained this season, from three dozen of eggs supplied by Mr. Cooper, of Limerick, twenty-two strong healthy chicks. A long railway journey seems more destructive to the vitality of eggs than a voyage by water. Where parties have the opportunity, we would recommend eggs being sent by water as far as possible—by the lakes rather than the rail.

Egg Story.—A student at one of our military academies had copied a drawing of a scene in Venice, and in copying the title he had spelt the name of the city *Vennice*. The drawing-master put his pen through the superfluous letter, observing, "Don't you know, sir, there is but one *hen* in Venice?" On which the youth burst out laughing. Being asked what he was laughing about, he replied he was thinking *how uncommonly scarce eggs must be there*. The master, in wrath, reported him to the colonel in command, a Scotchman. He, on hearing the disrespectful reply, without in the least perceiving the point of the joke, observed, "An' a varra natural observation too."

Markets.

Toronto Markets.

"CANADA FARMER" Office, Aug. 13th, 1868.

FLOUR AND GRAIN.

The produce markets since our last have been dull and uninteresting. Stocks of all kinds are nearly exhausted.

FLOUR.—The business done during the week has been very small. Stocks here are now nearly exhausted, and few or no lots are offering. No. 1 Super. is nominally worth $7, and spring wheat extra $7 25. In fall wheat flour there has been nothing doing—there is little demand for the higher grades. Buyers will not pay within 50c. for fall wheat flour of the price of strong fresh ground spring wheat flour.

Oatmeal.—The market is firm. Car lots are worth from $6.50 to $6.75.

Bran.—Worth from $10 to $11 per ton.

Wheat—The market has been unusually quiet. There have been almost no lots in the market. Spring wheat is scarce and in good demand for local mills. There are buyers at $1.60 for car lots. Fall wheat is dull of sale. A few car lots were offering during the week without buyers.

Oats—Scarce. Lots offering to arrive at 60c., without buyers; on the street 60c. would be paid.

Barley.—The season is this year expected to open earlier than usual. A few loads have already been brought into the market. To-day four were sold; the prices paid were 94c. 95c. 96c. and 97c.

Peas—Nothing doing. No stock in the market. Prices nominal.

We quote wholesale prices: Flour per bbl. superfine No. 1, $7 to $7 25. *Oatmeal*, per bbl. $6.15 to $6.25. *Bran*, per ton $10 to $11. *Wheat*, Spring, 60 lbs., $1 50. *Wheat*, Fall, 60 lbs., $1 48 to $1 50. *Barley*, 48 lbs. 94c. to 97c. *Peas*, 60 lbs., 85c. *Oats*, 34 lbs., 60c.

Hay—$12 to $10 per ton.

Straw—$10 to $12 per ton.

PROVISIONS.

Pork—Very light stocks in the market. Nominally unchanged, $23 to $23 50 for mess.

Cut Meats—Nothing doing. Quotations nominal.

Butter—Scarce, and held firm. Owing to the advance in gold there has been no export demand. Holders are asking from 15c. to 20c. for tub, according to quality, with buyers at from 16c. to 18c.

Cheese—Market firm. Holders are asking 11c., with buyers at 10c. for choice dairy.

Eggs—Selling at 10c. in lots, packed, with supply good.

Bacon—Unchanged. Cumberland cut worth 10½c. to 11c.

THE CATTLE MARKET.

A good number of cattle have been offering during the past fortnight, but principally inferior. First-class cattle have been scarce. We quote:—1st class $6 50; 2nd, do. $5 50 to $6 75; 3rd, do. $4 50. *Sheep* have been in plentiful supply, and of good quality. Trade has been brisk. We quote:—1st class $4 to $4 50.; 2nd, do. $3 75 to $4; 3rd, do. $2 75 to $3. *Lambs* have been in good supply and were readily taken up. We quote:—1st class $2 to $2 75; 2nd, do. $2; 3rd do. $1 50 to $1 75. *Calves*—The market has been well supplied, but the demand is not now so active. We quote:—1st class $6 each; 2nd, do. $4.75 to $5; 3rd, do. $3 to $3 25.

Wool—The market is firm. Small lots on the market sell at 27c.; a better feeling seems to prevail among dealers, and a few days ago a lot of selected combing sold as high as 30c.

Hops—Inferior per lb., 10c. to 15c.; medium do. 15c. to 25c.; good do. 20c. to 30c.

Salt—American bbls., $1 60. Liverpool, coarse, bags $1 to $1 10.

Hides and Skins—Hides, green, rough per lb., 6½c., do. green, inspected, 7c.; do. cured and inspected, 7½c. to 8½c.; Calfskins, green, 10c.; do. cured, 12c.; do. dry, 18c. to 20c.; Lambskins, green, 30c. to 35c.; Pelts, 25c.

Montreal Markets, Aug. 12.—*Flour*, superior extra, $7 60; extra $7 15 to $7 25; Fancy, $6 80 to $6 85; Welland Canal superfine, $6 65 to $6 70; Superfine No. 1 Canada wheat, $6 30 to $6 50; Superfine No. 1 Western wheat, $6 50 to $6 60; No. 2 do., $6 00 to $6; Fine, $5 60 to $5 65; Middlings, $4 75 to $4 80; Pollards, $4 25 to $4 40; Bag flour, $3 40 to $3 60. *Wheat*—Canada Fall, $1 50; Canada Spring, $1 55 to $1 60; Western, $1 44 to $1 45. *Oats*—Per 32 lbs. 48c to 50c. *Butter*—Dairy, 17c. to 19c.; store packed, 16c. to 18c. *Cheese*—Factory, 9½c. to 10½c. per lb.; Dairy, 9c. to 10c. *Eggs*—14c. to 15c. *Ashes*—Pots, $5 90c.; pearls, $5 50. *Pork*—Mess, $25; thin mess, $23 to $23 50; prime mess, $17 50; prime, $16 50c. to $16 70c.

Milwaukee Markets.—Aug. 12, noon.—Wm. Young & Co.'s report.—Wheat—Receipts, 9,000 bushels; shipments none; No. 1 wheat, quiet but firm at $1 83; No. 2 wheat, at $1 77½ to $1 78. Flour quiet. Pork unchanged and nominal.

Chicago Markets, Aug. 12, noon.—William Young & Co.'s report.—Wheat—Receipts, 46,000 bushels; shipments, 4,000 bush. No. 2 wheat, firm at $1 78, cash, and $1 70 in store, sellers' option all August. Corn active at $1 03½ to $1 03½; receipts, 151,000 bush; shipments, 106,000 bush. Pork nominal and unchanged.

THE CANADA FARMER is printed and published on the 1st and 15th of every month, by the GLOBE PRINTING COMPANY, at their Printing House, 29 and 31 King Street East, Toronto, Ontario, where all communications for the paper must be addressed.

☞ Subscription Price $1 per annum, (POSTAGE FREE,) payable in advance. Bound volumes for 1864, 1865, 1866 and 1867, may be had for $1 30 each. Subscribers may either begin with No. 1 of the present Volume, or with the first No. of any preceding volume. No subscriptions received for less than a year, and all commence with the first number for the respective years.

Communications on Agricultural subjects are invited, addressed to "*The Editor of the Canada Farmer*," and all orders for the paper are to be sent to GEORGE BROWN, Managing Director.

VOL. V. No. 17. TORONTO, CANADA, SEPTEMBER 1, 1868. POSTAGE FREE.

The Month.

EPTEMBER is one of the pleasantest months of the year. As June is a delightful compound of spring and summer, so September is an agreeable mixture of summer and autumn. We have mid-day heat, but it is tempered by cool nights. Indeed, some time this month, Jack Frost may be expected to appear on the scene, committing his first depredations on our melon, tomato, and grape vines, blanching the corn leaves, and putting the first faint hues of loveliness on the forest leaves. Summer will soon abdicate the throne, and after a brief October interregnum, Winter will be crowned king. On all the beauty and life of nature may now be clearly read the inevitable doom, "PASSING AWAY."

The mean temperatures for September, at the prominent Canadian points enumerated during the previous months of the year, are as follows:—

Stratford	53° 59'
Hamilton	58° 00'
Barrie	54° 51'
Toronto	56° 20'
Belleville	56° 29'
Montreal	61° 46'
Quebec	54° 40'
St. John, N.B.	55° 56'
Halifax	58° 00'

It has been well remarked that "when autumn days come, Nature, like a retired merchant, changes its manner from thrift and bustling industry to languid leisure and ostentatious luxury." But the farmer cannot yet play the retired merchant, though the air is deliciously restful, and the scenery suggestive of repose. The hurry of harvest is over; but not until winter fairly sets in can the busy farmer think of holiday. Chief among the duties of this month is the sowing of fall wheat. This crop is not now so widely grown as it formerly was, owing to the many uncertainties and disappointments that have attended it of late years. It is a question worth considering, whether it is not falling too much into disuse. In view of the superior quality and higher value of winter wheat, is it not wise to sow it, even though some risk is run of failure? The loss of seed is all that is hazarded, for the preparation of the ground is so much clear gain, even if it is found needful ultimately to sow spring wheat. If our farms had not been so absurdly cleared of everything in the shape of a green tree, if protective belts of timber had been left at proper intervals, one great cause of the failure of this important crop would never have existed. In the unsheltered condition of our grain fields, and our exposure to drought in summer, and bleak winds in winter, we are suffering the pains and penalties resulting from the wholesale and inconsiderate destruction of our forests. By all means have the patch of winter wheat. And if there be a field so situated as to be a protected nook, shielded by the woods from bleak, wintry winds, let that be devoted to this crop. It will pay to put land in the best order for fall wheat. It should be well enriched and made as mellow as possible. The best of seed should be got, carefully cleaned from all admixture of weeds or other grains, brined to destroy smut, and put in with a drill, *by all means*. All grain crops do best drilled in, and it is time broadcast sowing were altogether abandoned; but there is no crop that shows the advantage of the drill as does fall wheat. If the land is to be seeded down with timothy, it is better to defer that operation a fortnight later, than to sow the grass seed with the wheat. Clover seeding should be attended to as early as possible the ensuing spring. Fall ploughing is an operation that should not be neglected, and after the seeding for winter crops is finished should be continued as long as the state of the weather will permit.

Various other farm operations are in order this month. Not the least important is the care of fattening animals. It is a great mistake to defer feeding them for the butcher too late in the season. They improve in condition, if well fed, much more quickly in early fall than when winter sets in. This applies especially to hogs. They should be penned early, their styes kept scrupulously clean, and their food given regularly and abundantly. "Never," says the *Illustrated Register*, "keep them waiting for food, never let them squeal off their flesh." When we have the usual downpour of fall rain, September is a good month for butter-making. The winter supply should now be laid down, if it has not been already done. Corn must be harvested this month, and properly cured, the stalks will make excellent winter fodder. This is a source of fodder supply which is too little thought of by the generality of Canadian farmers. Many odd jobs lie in wait to occupy spare days and hours at this time of year. Meadows may be top-dressed, if there be well-rotted manure to do it with. Happy is the farmer who, notwithstanding the demands of the turnip field and fall wheat patch, has choice dung to spare for the meadow. It protects the grass crowns, and affords a cherishing mulch, while it stimulates an early and vigorous growth, when spring comes. Grubbing up bushes and briars, exterminating thistles to be found here and there in pastures, rooting out mullein and other weeds that disfigure the fence corners and road-sides, draining swamps, if the weather be sufficiently dry, clearing stones off pasture lots and fallows, preparing root cellars for being stored, picking out weeds from among turnips, to prevent their going to seed, fixing up cattle-sheds, repairing fences, are not these "chores" enough to show that there need not be an idle minute on the farm, betwixt this and the setting in of winter?

September is the month during which most of the Agricultural Exhibitions are held. It should never be deemed lost time, wasted money, or mere holiday-keeping to attend these. Much useful information may be obtained at such places, that is, provided those who go keep their eyes and ears open. "Eyes and no eyes," might be the title of a descriptive account of the manner in which two classes of persons, the observant and unobservent, demean themselves at shows. An enquiring mind will find enough to engage its best attention, and waken its fullest energies on such occasions, while a dull, sleepy mind will go and come like a door on its hinges. These exhibitions do much to keep the spirit of improvement alive, and are well worthy of encouragement and patronage from all.

Beyond the pleasant work of in-gathering, and the ceaseless fight with weeds, there is not much to do in the garden this month. Strawberry plants may be set out, and with careful tillage, weeding and watering, will yield moderately next spring. Land for new gardens or orchards may be got ready for spring operations by thorough ploughing, manuring, and mellowing. We prefer to plant both fruit and shade trees in the spring, though fall-planting has its advocates.

The apiary will need some attention in September. By the middle of the month the honey harvest will be quite over, and all surplus boxes not yet removed should now be taken off. Late or small swarms should be put together. One strong stock is better than two or three weak ones. Generally speaking, it is poor policy to feed bees, but if it must be done, now is the time, instead of disturbing them in winter. Watch against robbing, and if there are signs of it, contract the entrance to the hive, so that only a bee or two can pass at a time. Queenless stocks should either be joined to others, or supplied with queens. Look out sharply for the moth-miller.

The Field.

Irrigation.

The artificial irrigation of land has been practised from time immemorial, and is in some countries absolutely indispensable to successful agriculture. The ends sought by the operation are both the supply of requisite moisture in countries or seasons of deficient rainfall, and the addition to the soil of rich alluvial deposit left by the overflow and subsequent draining of river water. The most costly works have been constructed to effect the desired object; but in favourable situations the end has sometimes been attained by comparatively simple and inexpensive means. It is usually along the course of rivers only that this method of watering has been adopted, though in some instances water had been conducted for the purpose to a considerable distance, artificially raised above its natural level, and stored in ample reservoirs for the purpose of irrigating otherwise arid and sterile land. Most frequently fields thus irrigated have been sown to grass, and called water meadows; but in many countries the same plan of operations has been adapted to arable land, and water is thus regularly supplied to corn crops, being conducted over the ground between the ridges or drills of the growing grain. Great advantages have thus been secured, and the expense, however great, has been well repaid by the increased productiveness of the land.

Most of the water meadows in Britain are met with in Gloucestershire, Wiltshire and Dumfriesshire. In the first-named county a striking instance of the benefit derived from the process was afforded in the following case: A meadow of eight acres, in South Cerney was thus artificially watered, and the ordinary yield, even in dry seasons, is thus stated. The land was untouched till the 2nd of April, when it was let to be fed for five weeks by stock, as follows: 107 sheep, 8 cows, and 4 colts. After this the grass was allowed to grow, and fifteen tons of hay were cut; and subsequently the after-feed, valued at 25 shillings the acre, was again eaten off by stock. The profit was estimated at nearly £10 the acre. This land, which is now in the possession of a miller, was formerly occupied by a farmer, between whom and the miller some disagreement arose, in consequence of which the farmer was deprived of the use of the water. During that season, which was unfortunately dry, the whole produce of the eight acres was only three tons of hay. On the estate of the Duke of Bedford, there is a water meadow of nine acres, the yield of which is thus given:—During March 240 sheep fed on the grass for three weeks; in June, eighteen tons of hay were cut from the field; in August, thirteen and a-half tons were again mown; and in September, during the whole month, there was pasture for eighty sheep. The *Farmer* (Scottish), of the 5th August, contains an illustration of the value of artificial irrigation, in the following extract:—

"Robert Malabar, of Newcastle, in this county, describes the poor state of the grass crops on the land adjoining the Trent, which he says might have been improved by irrigation, and he gives an instance:—'A few years ago I designed and directed a diversion of a portion of the river Trent over nearly twenty acres of land, which was then partly a bed of rushes, &c., and on the whole worth about 20s. an acre to rent. It is now free from rushes, and affords a bulk of early spring eating, having this year mainly enabled the tenant to feed the lambs from 100 ewes till the latter end of May, and has since produced about two tons of hay per acre—(this may be considered an excess over the original produce, as the spring eating and after-math are now more valuable than the year's produce was ere the improvement was made)—which is now safe in the stack, and the tenant can apply the stream at once again if he chooses. The rental is now 60s. per acre. Thus, having seen the enriching capabilities of the Trent stream in this instance, I can see no good reason why a similar improvement might not be more generally made on the lands through which the river passes.'"

There is another very important application of irrigation which has quite recently received special attention, namely, the utilization by its means of the sewage of towns, which are thus emptied of what is noxious and pestilential to the residents, while land in the vicinity is at the same time vastly enriched.

The subject is one which may well engage the attention of thoughtful and practical men in this country, and is especially pressed upon the attention of agriculturists by the drought of the present season, indeed, we may almost say, by the yearly recurring drought of the country. It is beset, we admit, by difficulties of no trifling character, but in this age of ingenuity and enterprise these are not surely insurmountable; and while we would place our chief reliance on deeper cultivation, subsoiling, and underdraining, we do not think the subject of irrigation should be altogether ignored or neglected.

Lewis' Incline or Self-closing Gate.

At the last Provincial Exhibition Mr. Lewis exhibited a number of gates, and among those that received the commendation of the judges was the incline gate represented in the accompanying illustration, which will be readily understood by aid of the maker's own description as follows:—The cut

shows the side or front elevation of gate. It is made to slide on rollers placed between the upright frames and in the opening C. C. The gate is made in two parts, consequently this description of the left hand gate applies equally to the other half.

The top and bottom rails are made in the ordinary way, but the middle part of the gate is made by cutting a board anglewise. The board should be 10 feet long and 17½ inches wide, and is cut from 3½ inches *down* from the upper edge at one end, and 3½ inches *up* at the other end. This will form an incline of about one inch to the foot. The pieces when cut are then separated parallel from each other about 6 inches, which will admit of a batten, 1 inch thick and 3 inches wide, being nailed on the lower edge of the upper board, and of a 5 inch roller being inserted for the gate to work on. There are two rollers to each gate, there being one between each pair of posts, and in a line with the opening C, C. To lighten the appearance of the gate, tapering pieces are taken out of the wide ends of the centre-boards, as at D and A. It is very simply made, the battens being all scored into the uprights, and an inch batten is nailed on the face, thus dispensing with mortising.

The gate is made to close itself. A person passing through would simply push it open sufficiently to pass, and the gate will close after him spontaneously. If, however, it is required to open to the full width, to let a vehicle through, it is only necessary to push it to its full extent, when it will stop of its own accord.

The following are the chief advantages claimed for this invention. It cannot be left open by children or careless persons, and therefore is particularly adapted to dangerous places, or where it is absolutely necessary that the gate should be kept closed. Again, it lifts itself out of the snow in the winter, and further, it cannot easily get out of repair; as it does not swing out in the way, occupies no more space than merely its thickness, and even that will be close to a wall or fence, it takes but little room in a yard or enclosure of any kind. The hangings are cheap and the gate of good appearance.

Many of those gates are being erected in the city of Kingston, and in the counties of Lennox and Addington, and it will be on exhibition at the approaching Provincial Show in Quebec, and most probably also at Hamilton, where parties will have an opportunity of inspecting it and judging for themselves.

We direct attention to Mr. Lewis' advertisement in the present issue.

Soules Wheat.

To the Editor of THE CANADA FARMER:

SIR,—In your last number you notice having received a sample of very fine wheat from Mr. Samuel Berriman, of Stamford. And, from Mr. Berriman's remarks, the inference would be naturally drawn that the Soules wheat was, regardless of the midge, by far more profitable to raise than either the Mediterranean or Midge-proof. Mr. B. may be right so far as his own farm is concerned, which he describes as "a light sandy soil with a subsoil of gravel over one hundred feet deep." I know other localities where the Queenston limestone comes near the surface and forms a natural under-drainage, where they have continued to raise the Soules wheat with success. But what might apply to these exceptionably favoured localities will not form a rule for those not enjoying the same natural or artificial advantages of underdrainage. And I know from sad experience, that although I can raise straw six feet high and heads six inches long, since the advent of the midge the raising of the Soules wheat has been a decided failure with me, one fine crop of straw on fifty acres not paying for threshing. I know of some farmers in this neighborhood who persisted in raising Soules wheat until it nearly ran them ashore, which they richly deserved for continuing to propagate a pest in the country.

I do not think that Mr. B's comparison in the yield between the red and white wheat is quite right during the present reign of the midge. My two adjoining neighbours have threshed their crops, the one Mediterranean and the other Midge-proof, and in either case the yield was thirty-three bushels to the acre; had it been Soules, and no midge, I should have judged the yield would have been forty bushels per acre. And as regards the price, Mr. Berriman says that when red is $1.30 white is worth $1.75, which will not agree with the trade reports, which generally rate red the same as spring wheat, about 12½ cents lower than white. I have made the above remarks for fear that some not possessing the advantages of Mr. B. might be induced to follow his example to their loss.

R. N. BALL.

Holmehurst, August 10, 1868.

Salt.—Phosphoric Acid in Ashes.

To the Editor of THE CANADA FARMER:

SIR,—In your number of July 15th, I notice an extract from Johnstone's Lectures on Agricultural Chemistry on the value of salt as a manure. Some of our farmers in this section of the Province of Quebec have been using it latterly with great benefit to their grain crops, and in conjunction with animal manures there can be no doubt of its good effects, especially on dry soils.

From the same work I extract the analysis of the insoluble matter of birch-wood ashes, which is as follows:

Silica	5·50
Lime	62·20
Magnesia	3·00
Oxide of Iron	·50
Oxide of Manganese	3·50
Phosphoric Acid	4·30
Carbonic Acid	31.00
Carbon	
	100·00

For my own satisfaction I made some experiments to test the quantity of lime present in the ashes of the birch, and found the above substantially correct. The presence of phosphoric acid would show the value of these ashes as a manure for wheat, for Professor Dawson, in an address delivered in Montreal in the beginning of this year, conclusively showed how absolutely necessary to man's health and well-being it was that a certain quantity of this substance should be found in the soil. If it requires, as he then showed, but four-tenths of one per cent. to supply wheat with the necessary quantity of phosphoric acid, here is at once a means, too often utterly wasted, of restoring to the soil a part of what has been extracted from it. The unleached ashes of course, from not being deprived of their potash, are more valuable than the leached, of which the above is the analysis.

Trusting the above may be of use to some of your readers, I forward it for insertion, if you think it worthy of a place in your columns.

"GOSFORD."

August 6th, 1868.

Thin Sowing.—Have you tried it?

If not, pray do so, especially if you are a lover of £ *s. d.* No man should venture to say that such a thing will not answer, unless he can prove it has failed. A mere supposition or imagining in such matters has no value whatever. I have often brought color into the cheeks of agriculturists who stated positively that thin sowing would not answer, by mildly asking whether they had ever tried it?

There is nothing more easy than to try (as I have done) half an acre or an acre with a diminished quantity of seed, so as to deduce a comparative result. After some fifteen years of such experiments I have come to the conclusion that thick sowing in wheat, barley, and oats, not only wastes much seed, but inflicts a much heavier loss by preventing the full development of the plant, and thus greatly diminishing the crop in quantity and lessening its quality.

Farmers quite comprehend the necessity for giving ample room for the growth of their root crops, but it does not appear to me that they perfectly understand the nature of the wheat and other grain plants. I have heard many say that they sow thick to prevent tillering and to smother the weeds. Although I do not recommend a general sowing of so small a quantity as a peck an acre, I find that it produces an ample and superior crop, and it especially illustrates the natural habit of our grain plants, as may be now seen on half an acre in one of my wheat fields, the rest of the field, right and left, being a splendid crop, from one bushel per acre—my usual quantity. Both thick and thin were sown, or rather drilled and dibbled, on the 20th November, which would be naturally considered much too late for a peck per acre. Well, up it came, a single stem or bodkin from each dibble hole, and we could only see that there was any plant by placing our heads low to the ground and taking a horizontal view. In fact, it looked like a bare fallow from November to April, the rest of the field (one bushel per acre) looking thick and luxuriant.

In April, and early in May, it still looked thin, but the original bodkin gradually surrounded itself with from thirty to fifty other juvenile bodkins, shooting out horizontally. Well might the able and amusing correspondent exclaim, "Where can the wheat have come from?" Now (on the 20th June) the half acre strip of fallow has become a fine standing crop of wheat, with ears and kernels fifty per cent. larger than its neighbour. I have been amused by saying to my farm visitors, "you will soon come to the peck an acre," and several walked past it without distinguishing it from its competitors on either side. They evidently looked for a thin crop, which is not now to be found. I could, in the course of several years of experiment, have won a small fortune in wagers. But it is not strange that among some 400,000 British farmers, it is Mr. Mechi only that tries and records these important experiments. Can it be a matter of indifference whether in seed alone we pay ten shillings per acre more or less? The field in which this peck an acre is sown will probably produce six qrs. of wheat, perhaps even more, so that the poor peck has a strong competitor. Which is to be the winner—the peck or the bushel? We shall all know some day. In 1864 and 1865 the peck gave a crop of seven qrs. two bushels, and seven qrs. one bushel—the best on the farm, and the finest sample, for I can distinguish the heap of thin sown grain at once, by its superior size and quality.

It has often surprised me that nearly every kernel vegetates, which is contrary to the opinion expressed by many. As we only put one kernel in each hole, we are enabled to see where any failure takes place. This is the fifth year of the peck an acre experiment, and it certainly promises to be an abundant crop. Farmers who sow two and a half to three bushels of wheat per acre, and five bushels of oats, seem surprised at the level or even appearance of the heads of corn. An up-and-down crop, like a mixture of tall grenadiers and tiny riflemen, is a sure consequence and evidence of a grand battle, in which the weaker have gone to the wall.

Mr. Hallet is doing an incalculable amount of good by laying down rules for the thin planting of his wheat and other grain.—*F. G. Mechi, June 24.*

Fall Ploughing.

Without elaborating the many strong points in favor of fall ploughing, a few of the more prominent benefits may be briefly stated as follows:—

1. August and September is a good time to turn over bound out sod land, and manure and re-seed it at once to grass, obtaining a crop of hay the following year.

2. October and November is an excellent time to break up sod land for planting the following spring.

3. The weather is then cool and bracing, and the team strong and hearty for their work; while the weather in spring is more relaxing and the team less able; and spring work being always hurrying, it saves time to despatch as much of the ploughing as possible during the previous autumn.

4. Sod land broken up late in autumn, will be quite free from growing grass the following spring, the roots of the late overturned sward being so generally killed by the immediately succeeding winter that not much grass will readily start in spring.

5. The frosts of the winter disintegrate the ploughed land, so that it readily crumbles in fine particles in sprlog, and a deep, mellow seed bed is easily made. The chemical changes and modifications resulting from atmospheric action during the winter, develop latent fertility in the upturned furrows, which, with the mellowing influences, materially increase the crops.

6. Most kinds of insects are either wholly destroyed or their depredations materially shocked by the late fall ploughing.

7. Corn stubble land may be ploughed late in the fall, and thus be all ready for very early sowing in spring, thereby going far to insure a good catch of grass; the roots of the new seeding hold well, being well established before the droughts of the summer come on.

8. Most land needs deeper ploughing than has generally been practised. Where the sub-soil is fine grained, unctuous and close, or where there is a hard pan of good quality, deep ploughing may be at once resorted to, with decided advantage. Where the sub-soil is poorer, the ploughing may still be advantageously deepened by degrees, say an inch at each new breaking up. But in by far a majority of cases, deep ploughing may be practised at once—indeed, it may be the *rule* with safety, while shallow ploughing may be the *exception*. Plough say nine, ten, eleven, or twelve inches in November. The sub-soil turned up will grow several shades darker by spring. The frosts and atmospheric influences of winter will mellow the soil; the inorganic elements, and all latent fertility, will be made more active for benefiting the crops.

In spring, spread the manure and plough it in, or otherwise work it in or mingle it with the soil, to the depth of four inches, or a little more or less, and you have the very best attainable condition for realizing good crops. Deeper ploughing may thus be practised than would at all times be safe, or expedient, if the ploughing is delayed till spring.—*Maine Farmer.*

Treatment of Clay Land.

I had a patch of hard clay land in one of my fields, containing about half an acre; it was so hard that we could not plough it with two horses, and when it was ploughed, it came up in large lumps from one foot long to three; the harrow would bound and bounce along over it, and you could not see where it had been; we could not plant it for the lumps. It was a source of trouble and vexation to me, and I determined to do something with it; so I went to work. I put a large blind drain through the middle of the patch; this was my main drain. Then I ran from the main drain small ones each way, twenty feet apart, to the outside of the clay patch. I laid in a two inch tile drain. Then I drew on a large amount of corn cobs and coarse manure; then summer fallowed; then in the fall, I drew on a large amount of well rotted manure, and sowed wheat, and it was by far the best wheat that I had in the field, and I never after saw any clay lumps to speak of in the patch. It was the best land to plough that I had, and raised the largest crops, and I am satisfied that if farmers would drain and manure their clay lands heavily, it would richly pay them for the trouble and expense, and be a saving in horse flesh and harrow teeth.—*Cor. Country Gent.*

When to Sell Grain.

The *United States Economist*, after speaking of the abundant grain crops in this country and Europe, and the prospect that, as a consequence, the prices of grain will gradually decline to a certain extent, says:

Our surplus, whatever it may be, will have to be sold in the Liverpool market, and must come down to the prices there current, and the price at which we can sell the surplus will determine the value of our entire crop. The farmers would do well to look these probabilities fairly in the face. If they hold back their produce, in consequence of declining prices, they may delay the shipment of our surplus for a few weeks or months, but ultimately they will suffer from a decline much more extreme than would otherwise have occurred. Year after year has the West adopted the policy of keeping back its supplies until the close of navigation, compelling England to supply her wants from Europe, the result being that in the spring the surplus is rushed to the seaboard, and, under the pressure of receipts, prices fall, and Liverpool is enabled to make its own prices upon the grain we are obliged to realize upon. As a rule, an early market is always the best for the farmer, and especially so in periods of abundant crops.

SHARP IF TRUE.—The latest swindle is a Rochester, (N. Y.) invention. When hay is sold by the ton, a man conceals himself in the load and is weighed with it. While the load is driven to the barn of the purchaser, the man leaves his hiding place and goes back to the hay-market to be sold again. The trick was not discovered till last week, though it is understood that it has been practised for years. *Ex.*

RINGLEADER PEAS.—Our quotation from the *Mark Lane Express*, and remarks on the difference between the English and Canadian ideas of "quick growth," have elicited the following communication from a correspondent in Pickering:—"In the CANADA FARMER of Aug. 15th, on page 254, there is a short paragraph on the early growth of Sutton's Ringleader Peas in England. For your information I may say that I procured, last year, one quart of the same peas from Mr. James Fleming to grow for seed. The spring of 1867 was wet, and I did not get the ground in a state to please me until the 31st May, when I sowed them; and I harvested them fully ripe on the 24th July. This year I sowed the produce (about one peck) on the 9th May, and harvested them fully ripe on the 13th July. The difference in the time of growth will thus be seen to be rather less in Canada than half that of England."

MEASURING GRAIN IN THE BIN.—The rule and mathematical calculation for measuring grain in the bin will be found in the first volume of the CANADA FARMER, page 175. It is in the number for June 15th; to which we refer our correspondent from Hilton. A simpler method, sufficiently accurate for all practical purposes, is given on page 200 of the same volume. It is the method we have usually employed, and as it may be useful to many farmers at the present season, who have not an opportunity of seeing the back number referred to, we here repeat it:—Multiply the length, breadth and depth of the grain together in inches, and divide the product by 2,150 (the number of cubic inches in a bushel), and the quotient will be the number of bushels in the heap or bin.

Canadian Natural History.

Canadian Martens.

Of the Weasel family two species, the Mink and the Skunk, have already been briefly described and illustrated in these pages. The accompanying engraving represents two other members of the same group. The larger animal is known in some localities as the Fisher, (*Mustela Canadensis*); it is also sometimes called the Black Cat, or in other parts it goes by the name of Wood-Shock or Pekan. It is the largest and most powerful of the tribe. The specimen in the University Museum, from which our illustration was taken, measured fully three feet, the head and body being two feet long, and the tail rather over one foot.

The animal possesses in a marked degree all the peculiarities of the genus, in the long agile body, short legs, alert motions, sharp and powerful teeth,

and carnivorous habits. The color is a dark brown verging to black, somewhat greyish over the head and inferior parts of the body, but deepening into blackish towards the hinder parts. Its general color is indeed so dark, that among hunters it is frequently called the black cat. The head is broad, the nose acute; the ears are broad, round, and wide apart. The canine teeth, especially those of the upper jaw, are long. The fore feet are shorter than the hind feet, which are covered with hair. The toes are partially connected with a short hairy web. The tail is long, bushy, and pointed.

The fur is long, fine, and lustrous, increasing in length towards the posterior parts of the body. It consists of two kinds of hair—a short brown down, and longer and more rigid hairs. These are longer and blacker in winter than in summer. The color is subject to some variation, and there is one variety altogether white except the nose and feet. The general color of the long hairs already spoken of, however, is dark brown. On the head, neck, and upper and fore parts of the body, these brown hairs are tipped with grey, giving a hoary appearance to the fur of these parts, but towards the posterior parts the color is more uniform, and deepens into black. There is sometimes a white spot on the throat, and traces of a similar spot on the belly.

The Fisher is a large, powerful, and somewhat formidable-looking animal, standing about a foot high. It chooses its abode usually in the neighborhood of some swamp or lake, and feeds, like the rest of its family, on the smaller mammalia, or even on birds, frogs, snakes and other reptiles. It is especially fond of fish, and hence has obtained one of its popular names. It often robs the hunter's traps of the fish used as bait. It breeds once in the year, bringing forth two at a birth. Its geographical range extends across the continent from the Atlantic to the Pacific, and between the 40th and 70th parallels of latitude.

The smaller figure in the illustration represents an animal called the American Marten, sometimes American Sable (*Mustela Americana*), closely resembling and sometimes confounded with the Pine Marten of Europe. The head of this species is long and pointed; the ears broad, short, and somewhat acuminated. The eyes are small and black, the body elongated, the tail bushy, and somewhat enlarged towards the end. The toes are furnished with long, slender, and compressed nails, nearly covered with hair. The color varies considerably according to age, season, and locality. A yellowish brown or fulvous hue predominates in its fur. The head, neck, throat and upper part of its body, are of a yellowish white. The whole length of the animal is about two feet, including the tail.

The American Sable is a pretty and active little animal, inhabiting elevated wooded districts, making its habitation in hollow trees, and supporting itself on the usual fare of its genus. It is extremely prolific, bringing forth six or eight at a litter. At the time when the beech-nuts are ripe the hunters say it will not touch bait, and it is supposed by them to feed on this vegetable diet; but the more probable explanation may be found in the fact of the abundance of food attracting to the beech trees at this season the smaller animals that feed on nuts, and who become an easy prey to their quick and voracious enemy, the Marten, who thus profusely supplied with its natural food, is not tempted by the hunter's bait. Like the preceding species it has a wide geographical range on this continent, extending from the 40th to the 68th parallel of latitude.

Martens are said to be capable of domestication, but they are of very uncertain temper, and can never become very trustworthy pets. Their fur is of considerable value, and destitute of any of that offensive odour which characterises some of the weasel family.

On Skinning Quadrupeds.

When a quadruped is killed, and its skin is intended for stuffing, the preparatory steps are to lay the animal on its back, and plug up its nostrils, mouth, and wounds, if any, with cotton or tow, to prevent the blood from disfiguring the skin. A longitudinal incision is then made in the lower part of belly, in front of the pelvis, and extended thence to the stomach, or higher if necessary, keeping straight if possible. In this operation the hairs must be carefully separated to the right and left, and as few cut as possible. The skin is also turned back to the right and left, putting pads of cotton or tow between it and the muscles as you proceed in skinning. If any oily matter should make its appearance on the skin it must be wiped away. Now remove the skin in every direction as far as the incision will admit of. Each of the thighs must be separated at its junction with the pelvis, that is, by the head or ball of the thigh bone. The intestinal canal is next cut across a little way above the anus, and the tail is separated as close to the animal as possible. After this, the pelvis is pulled out of the skin and the skin separated from the back, with the handle of the scalpel passed between it and the carcass. It is pulled gradually upwards until the operator reaches the shoulders. The whole hinder parts and trunk of the body being thus out of the skin, the next operation is to remove the fore legs by separating them from the body at the shoulder joint. When the joint of one shoulder has been separated from the body, the leg is [illegible] into the skin, and the animal turned, in order to repeat the same with the other side, the limb of which

is also returned. The skin is then removed from the neck. The next thing is to separate the skin from the head. By the assistance of the knife, it is taken off as far as the nose; while great care must be taken not to injure the eyelids, and to cut the ears as close to the skull as possible; and also to avoid cutting the lips too close. All this having been performed, the head and trunk are separated from the skin. The next operation is to remove the head from the trunk at the upper bone of the vertebræ. The external muscles of the head and face are then cut off, and the bones left as free from flesh as possible. The occipital bones are next opened with a strong knife, and the brain all carefully removed. The fore legs are now pulled out of the skin, by pulling the legs one way and the skin another, as far as the claws of the foot. All the muscles are then cut off the bones, while care is taken not to injure the ligaments and tendons. They should be left adhering to the knee. They are then returned into the skin again. The hind legs are then treated in like manner. The tail is the last part skinned, and this is a more difficult task than the other parts of the body. Two or three of the first joints of the tail-bone are first laid bare by pulling the skin back. They are then tied with a strong cord, which must be attached to a strong nail or hook on the wall. A split stick is then put on the tail-bone and forced to the extremity, and the tail-bones come out of their enveloping skin. The skeleton head having been divested of all its fleshy matter, tongue, palate, external muscles, and brain, is now returned to its place in the skin, which is in a condition for commencing the operation of stuffing.

A. B. B.

☞ A Chicago school marm while giving her class some oral instruction, in natural history, defined an amphibious animal as one that could not live in the water, and that died if you took it on dry land.

Hints for the Management of Gold Fish.—Gold fish may be kept ten or twelve years in vessels, (their average period of existence), by the following precautions: 1. Allow not more than one fish to a quart of water. 2. Use the same kind of water, whether spring or river water, and change it daily in summer: every other day in winter. 3. Use deep rather than shallow vessels, with small pebbles at the bottom (to be kept clean), and keep them in the shade, and in a cool part of the room. 4. Use a small net rather than the hand while changing the water. 5. Feed them with cracker, yolk of eggs, lettuce, flies, etc., rather than with bread, and then only every third or fourth day, and but little at a time. 6. Do not feed them at all from November to the end of February, and but little during the three following months.—*Ex.*

English Sparrows.—In the spring of 1866 four pairs of English sparrows came to the Union Square Park, New York, and there built. Three pairs occupied the trees, one ejected a wren from her little house, the only bird-house then in the square, and took possession; a fifth built in the ivy of Dr. Cheever's Church, facing the square. The industry of these little fellows in devouring the measuring worm (so great a nuisance that most persons avoided passing through the park, preferring to go around during their occupancy; and so numerous were they that they did not leave a leaf on any tree except the ailanthus), was such that boxes were provided on almost all the trees for them. They were very prolific, these hatched in the spring rearing a brood in autumn, and the old pair rearing four or five broods. In one year they increased from five pairs to a flock of seventy, and they are now estimated at six hundred. Last summer a reward of one dollar a head was offered for worms, but the birds had eaten the last one; they also eat moths, grasshoppers, and many other insects. These birds have extended about forty miles in every direction. The estimate that they destroy in Europe one-half million bushels of grain was probably correct; but how much, more or [illegible] did the insects they devour destroy? The question is, simply, which is the greatest evil, worm or bird, and which most readily controlled?—*Ex.*

Stock Department.

An American's Account of a Canada Stock Farm.

Mr. Sanford Howard, Secretary of the Michigan State Board of Agriculture, gives the following interesting details of a visit recently paid by him to Moreton Lodge Farm, Guelph:

"Fred. Wm. Stone, Esq., of Guelph, came from England and settled on land which he now owns, before it was surveyed, upwards of thirty years ago. He has now under occupation, in two farms, about eight hundred acres. Much of the soil of the principal farm, near the town of Guelph, required draining, which has been done with tiles to a considerable extent. It is very productive in grass, barley and oats. A large field of barley on a drained swale or swamp is very promising, and a field of twenty acres of oats, on another part of the farm, is the most luxuriant I ever saw—the oats standing thick and even on the ground to the height of nearly five feet. Spring wheat is grown instead of winter wheat, as being generally a more sure crop. Several large fields of this grain look well. Some fields of winter rye indicated a large yield. Roots, chiefly mangel wurtzel and swede turnips, are largely cultivated, that is, what a "States" man would call so, but not very largely compared with English practice. Mr. Stone usually has fifty acres a year. The crop is stored partly in pits and partly in cellars at the barns. The bulbs are chiefly pulped and mixed with hay and straw, according to the most approved English custom. Mr. S. thinks this much the most profitable mode of feeding roots.

The Stock bred by Mr. Stone consists of Suffolk horses, Short-Horn and Hereford cattle, Cotswold and South-Down sheep, and Berkshire swine.

Of the Horses, there are an imported stallion and three imported mares. The former is only three years old. He was bred by Thos. Crisp, of Butley Abbey, Suffolk, a well-known breeder of this kind of horses, as well as of Suffolk and Essex swine, whose *Show* stock I have several times looked at with much satisfaction in England. Mr. Stone's horse—or rather *colt*—is seventeen and a-half hands high, well proportioned, of strong bone, and good action. He has worked on the farm, at the plough, or whatever implement it was most desirable he should draw, every working day since the season opened. He works kindly, has a quick, lively walk, which carries him over a good deal of ground in a day, and does not tire or sweat much. He is in good condition—though doing service as a stallion, besides the work mentioned. The mares also work on the farm, and work well.

The Cattle consist of about fifty head of each of the two breeds mentioned, together with several grades of various ages, which are reared chiefly for beef, though heifers are occasionally selected and kept for milch cows. The origin of the Short-Horn and Hereford herds is so well known that I need not refer to it here. The number of prizes annually awarded to Mr. Stone, at Provincial and other shows, indicates the position which his stock occupies before the public.

Among the Short-Horns is the superb bull Grand Duke of Moreton, 5732, which took the first prize as a three-year old at Kingston last year—an animal of great weight for his age, and one of the best shaped I have ever seen of the breed. The even balance of his fore and hind-quarters, the obliquity of his shoulders, fulness of crops, depth and rotundity of carcass, the perfect straightness and great breadth of back, combine to make him one of the most majestic animals I ever looked at. Of the young Short-Horn bulls, several are very promising, particularly one about nineteen months old, by Grand Duke of Moreton, out of Duchess of York 3d, by Moreton Duke, 5225. He now promises to equal his sire in beauty, if not in size. Several cows of the Isabella and Marigaret tribes maintain their places in the herd, never failing to attract the attention of visitors. I have not space to speak of their respective points in detail.

The Herefords have latterly been increasing in numbers on the farm, and this increase will probably be allowed to continue. After seven years' experience with them, their good qualities have been so prominently displayed that Mr. Stone has determined to adopt them as a permanent stock. They are found to be healthy, hardy, easily kept, fattening rapidly whenever they have a fair chance, and producing the finest quality of beef. They are by no means the inferior milkers which the advocates of rival breeds frequently represent. Comparing them with the Short-Horns kept on the farm, all persons who have had anything to do with them concur in stating that the Hereford cows give, on the average, at least as much milk by the season as the Short-Horns, while some experiments that have been made show that in richness of milk the Herefords are superior.

I think Mr. Stone is entitled to the thanks of the public for the fair comparison he is making of the two breeds. We want just such means of ascertaining their real merits as he proposes us. The course too often adopted rests merely on the question of how the most money can be made by *speculating* in cattle. The profits which stock would afford if kept for ordinary products, and disposed of in the legitimate markets, are but little regarded; and we get but little light on the question whether one breed or another would be more profitable under given circumstances.

I have on former occasions spoken of the individual characteristics of some of Mr. Stone's Herefords. I will only remark here that the animals reared from year to year keep up the standard formed by the imported stock; and when it is considered that the original stock was *selected* from herds accounted among the best in England, this result must be regarded as of much importance in reference to the uniform excellence of the breed.

Many of Mr. Stone's grade cattle are half Hereford, and a few are three-quarters of that breed. They show the leading characteristics of the Herefords very strongly. Some of them are cows, now giving milk, and they are good-sized, handsome animals, with indications of being good milkers. A lot of yearling and two-year old steers are about as promising, in reference to thriftiness and fattening tendency, as any grade animals of their age that I remember to have seen. Some of the steers have been subjected to the yoke, and bid fair to make active and powerful oxen.

The Sheep consist of about five hundred head, three hundred and fifty of which are Cotswolds, and the rest South-Downs. They are all in fine condition. While I was there, Mr. Stone sold fifteen yearling Cotswold rams and two ewes to Mr. E. Whitby, for Dr. B. Bryant, of San José, California. The rams are to be used in crossing with sheep which have been bred from the old Mexican stock and the Merino. The result will be known in due time.

Mr. Stone has about thirty Cotswolds which he proposes to fatten next winter. Some of them would be called "hog-fat" now. If they go to "the States" when they are "made up," we shall probably see some of the fattest and heaviest carcases of mutton that have been known in the country. Mr. S. informed me that the fleeces of his yearling Cotswold rams (upwards of forty, I think,) averaged this year about eighteen pounds each, unwashed. One weighed twenty-four pounds. The sheep, after being shorn, weighed from 210 to 300 pounds—the weight depending, of course, much on the manner in which they had been fed.

Mr. S. informs me that, when he introduced the Cotswolds, there was nearly as strong a prejudice manifested against them as there was subsequently to the Hereford cattle. The sheep have nearly conquered the prejudices against them, and the cattle will probably do the same, if Mr. S. carries out his plan.

The South-Down sheep are bred from the Webb and other noted English flocks, and many of them are very handsome specimens of the breed.

Some of Mr. Stone's land lies so far from his principal farm steading, that it cannot well be manured in the ordinary way. Very large quantities of rich manure are made, but it is chiefly applied within a distance convenient to haul it. The mode adopted with the out-lying lots, is to feed off successive crops with sheep, until the desired fertility is obtained. First, a crop of rye is sown in the fall. If it gets strong enough before winter sets in the sheep are put on it. The next spring the sheep are turned on at the proper time, and the rye kept fed down as long as it continues to grow vigorously. When the growth of the rye is checked, the ground is ploughed, and sown to oats and vetches, which are fed off, and, when this crop is done, the ground is again ploughed and sown to rape or turnips, which are fed off in like manner.

Mr. S. has several fields where this course is now going on. His rams, which are intended for sale this fall, are on a field on which the second crop (oats and vetches) is just giving way to turnips and rape. The sheep are in high condition, and the ground is already well manured, though the feeding off of the third crop will enrich it still more. The sheep, of course, have been *well fed;* when the green crop would not afford them enough to eat they have had peas, or other additional food. The mode of feeding the green crops is that adopted in England, enclosing with hurdles a certain extent, on which the sheep are put from day to day.

This is a practice which I think might be introduced into this country with good results. Our people hear of the English farmers enriching their land by sheep farming. But it is quite a different thing from turning sheep on to the land, to live or die from the grass and weeds that may grow—often to gnaw the grass to its very roots, and starve the sheep besides. The sooner it is found out that *this* kind of sheep farming does not enrich the soil or its owner the better for the country."

☞ Cotswold sheep are said to be in greater demand in England now than ever before. At a late sale, 55 averaged $150 in gold.

☞ A Western editor relates a story of a man who bought a lot of hogs in Illinois and drove them slowly to Chicago. He was compelled to sell at a loss of $400. Returning home he was asked by his neighbours what were the profits of the operation. "Well," said he, "I reckon I didn't make much money out of the trip, *but I had the company of the hogs down.*"

VALUABLE IMPORTED STOCK.—The Montreal *News* says:—"The celebrated stock-beast which Mr. Cochrane daily expects from England, for which he has paid $5,000, is a heifer, we believe, of not more than two years old. This looks an enormous price, but the seller, far from abating his price, positively refused to sell the heifer unless he was furnished with proof that she would be taken out of the country and never brought back. It was only by binding himself down to fulfil these conditions that Mr. Cochrane was allowed to become the owner of the animal. He paid on a previous occasion $3,000 for a heifer which he bought in the United States, and the value of the stock on his Compton farm, when the English heifer arrives, cannot fall short of from seventy to eighty thousand dollars."

The Dairy.

Milking Cows before Calving.

I have practised taking it away for four years, in every case but one, which was a heifer that calved unexpectedly in the pasture. Her bag became considerably inflamed, but none of the others became so. A heifer coming four years old, dropped her second calf last night, March 20. Four days before, the 16th, I took three quarts; on the 17th three quarts; the 18th, six quarts; 19th, twelve quarts; 20th, ten quarts, and the milk all right for use now. She had been milked thirteen months, and had been dry thirty-five days previously. She has a very fine and large half Ayrshire calf. In my observation, milk rarely comes into the udder much more than thirty-six hours before calving; but when it does, I think it is better to be taken out, and by so doing have not known any injurious effects to follow.—LACTIS, *in N. E. Farmer.*

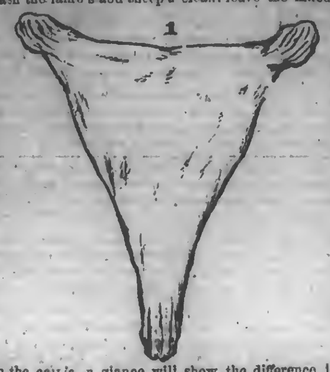
Rennet.

To the Editor of THE CANADA FARMER.

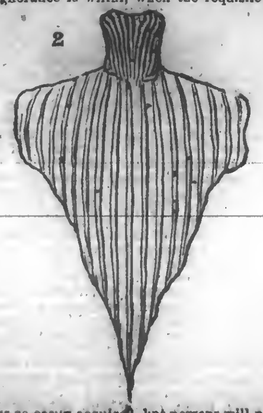
SIR,—I have been much surprised at the wilful ignorance of many who are engaged in the cheese factory business in Canada. As an example of not uncommon mistake amongst them, I may mention that most important article in cheese-making—one indeed that cannot be dispensed with or supplanted by any substitute yet found—namely, the inner coating or membrane of the fourth or true digesting stomach of the sucking calf, and commonly called rennet. It will be plain to any one who will reflect on the subject, that the best article to digest (it is at all events the first stage in digestion) a given quantity of milk is that which is taken from the animal whose natural food is the milk of the cow. The best rennets (or as they are called in some parts of Britain, *Vells*) are those taken from calves that have not eaten any other food than that obtained from the mother. Such rennets should not be objected to on account of the small size; for the quality of them is far beyond those taken from animals that are fed on herbaceous food. I do not wish it to be inferred that the large rennets should not be used, but that to use some of the small with them will be beneficial, and counteract the strong tone of the coarse ones.

Many persons have been deceived by buying sheep's maws. There is no excuse for such a mistake, as the difference between them and those of calves is very apparent. It is very important for the interests of the cheese business in Canada that in this matter, as well as in regard to cleanliness, and other necessary conditions of success, the manufacture should be carried on only by those who are thoroughly acquainted with all the details, and who will conduct the business with intelligence, care, and the strictest integrity. It is not likely to gain anything in the hands of the inexperienced speculators who take up the business one season and discard it the next.

Any person can discriminate the different kinds of rennets by a simple inspection. Let him take a calf's stomach, say one week old, that has had only the mother's milk, and when the stomach is empty—a lamb's—say four months old—and a sheep's of two years old—cut open all three, including the manyfold; wash the lamb's and sheep's clean, leave the mucus



on the calf's, a glance will show the difference in colour, shape, &c.; the manyfold of the sheep and lamb will be of a palish leaden hue, and the other of a greenish yellow, and the membrane of the calf's maw will be flesh-coloured, and uniform throughout; whereas the valves or folds in the lamb's and sheep's maw will be numerous and wide. The manyfold on these is also larger, and the valves deeper and serrated on the edges. That of the lamb of four months will be larger than the ordinary one from calves of one week, from the fact that a larger quantity of herbacious food is required in the former case. I have prepared one of each, and will leave them with you for the convenience of those who wish to see for themselves, and who may not have the means near at hand for taking the proper observation. There have been hundreds of sheep's and lambs' maws sold in Toronto to unsuspecting parties; few butchers in the city kill at a time so many as a score, yet they have these so-called rennets to sell by hundreds. Surely that ignorance is wilful, when the requisite know-



ledge is so easily acquired, but persons will not give themselves the trouble to make themselves acquainted with the plainest and simplest facts.

MARTIN COLLETT, Toronto.

NOTE BY ED. C. F.—The annexed illustrations, copied from the specimens left at this office by Mr. Collett, show the difference between the two maws, fig. 1 representing that of the calf, and fig. 2 that of the lamb, cut open and spread out.

Spots on Cheese.

To the Editor of THE CANADA FARMER:

SIR,—For a time, now, since the water in the well at our factory has been low, our cheese has on its surface dark spots, after standing on the racks from nine days to two weeks. These spots can be easily scraped off. Through the cheese there appear to be dark veins also; and it appears to be a little strong. The water referred to is what is generally termed sulphur water, it having a nauseous taste, and there collecting on the inside of the pump, a dark, slimy sediment, which feels quite gritty to the touch.

Now, what we wish to know is, can that appearance in the cheese arise from only soaking the rennets, and washing the cloths and vats with such water? We use English rennets.

J.

NOTE BY ED. C. F.—We think it not unlikely that the mould, or fungus growth (for such most likely it is), referred to by our correspondent, may be caused by the impurity of the water.

THE LAST MILK FROM THE UDDER.—D. Anderson says he has found by practical analysis in one instance that the last cup of milk drawn from the cow's udder contained sixteen times as much cream as the first one. This separation of cream from milk takes place in part in the udder of the cow, particularly if the cow is suffered to stand at rest for some time previous to milking. If there are people who doubt that there is a difference in richness of milk first drawn from cows and that of the last drawn, their doubts will be speedily removed by milking half a dozen cows and setting the first half drawn from each cow separate from the last half.—*Utica Weekly Herald.*

Entomology.

Entomological Queries.

To the Editor of THE CANADA FARMER:

DEAR SIR,—A few days ago, on looking at my young apple trees, I noticed at the extreme ends of the young wood, (1) a great quantity of small green lice, and a number of ants moving about after them. Curiosity led me to make a closer inspection, and on applying the microscope, I found the ants had an object in view in attending to those gentry. They would brush the lice with their horns and the lice would then eject a small quantity of fluid matter, in appearance like the gum which you will generally find on the tops of cones on balsam trees. I find that after a time those lice get transformed into a small black fly. As my trees are badly affected, I would like to hear from you (through the CANADA FARMER) if the insects are injurious to the trees, and also the best remedy for the evil. (2) I also enclose three caterpillars of which I have found a number this season. I find them very destructive to the young branches, completely eating off all the buds and foliage. I suppose the only remedy for these pests is to search for them and destroy them.

(3) I also enclose a few cocoons on a leaf, the first of the kind I have seen. I found three leaves covered with them on the same tree, and the leaves partly eaten, as the enclosed. (4) On another leaf you will find a number of cocoons or cells very small, and of a brown colour, grouped together in a small circle. By applying the microscope, they have the appearance of a shoe. I would like to have their history and habits. (5) You will also find a nest of insect eggs which are too often found in orchards. I would like to be informed what kind of an insect it is that deposits the eggs, so that it can be destroyed, as the caterpillars or worms the eggs produce are very destructive to the trees.

W. M. H.

NOTE BY ED. C. F.—(1) We gave an account of the very singular habit that ants have of *milking* the aphides, as described above by our correspondent, in

an article, entitled "Ants and their Cows," which appeared in the CANADA FARMER of Feb. 1, 1867, page 47. We are always glad to find our statements corroborated by the descriptions of independent witnesses, and also to learn that the many strange and wonderful habits and instincts of insects attract the attention of numbers of our readers all over the country. We can assure them that the more they investigate these marvels of nature, the more they will find to wonder at and admire, and the more pleasure they will derive from the contemplation. Plant-lice, or aphides, are of course injurious to any tree that is numerously infested by them, inasmuch as they draw away from it an immense amount of sap—the tree's life-blood. In the case of the apple and cherry, however, we think that where the plant-lice attack only the terminal shoots or new wood, they do more good than harm, as they act as a natural summer pruning, and by checking the excessive growth of the ends of the boughs cause more fruit spurs to be put forth lower down. Where it may be deemed needful to destroy these insects, we would recommend watering with strong soap-suds—a remedy we have found very efficacious ourselves. Our correspondent will find a short account of the natural history of the aphides in the CANADA FARMER of last year (Aug. 15, page 252), and a description with figures of their natural enemies in the same volume (Sep. 2, page 268). (2) These caterpillars were dead and shrivelled up when they reached us, and therefore hard to determine, but we believe them to be specimens of the yellow-humped caterpillar (*notodonta concinna*), of which we have given descriptions and figures in a foregoing article. This makes another locality for the insect.

(3) This is one of the oddest specimens that we have ever seen: a leaf with great nicks eaten into it, and on its under side seventeen—we hardly know what to call them. They are apparently the dead bodies of caterpillars, killed in the very act of eating, and enclosed in an ashy white silken shroud, through which appear the black warts and spines of the caterpillar's skin, and thus forming rather tough cocoons, fastened to the leaf with silken threads. They are all empty, and have each an irregular hole, apparently eaten through, near one end; inside them are the remains of a brownish chrysalis skin. We fancy the whole is the work of an ichneumon, which has eaten the original caterpillar, formed a cocoon of his skin, completed its transformation inside, and then eaten a hole through when ready to emerge as a perfect winged insect.

(4) This is another curious specimen, differing from anything we have seen before. On the under side of a portion of a leaf are grouped together in an irregular circle, with their tails on the outside and their heads pointing inwards, thirty-two empty chrysalides, probably of some tiny moth. Each one is about one-tenth of an inch in length, of a brownish color, and attached to the leaf by its tail, the head being free. The hole at the head, caused by the exit of the insect, gives them very much the appearance of a shoe or slipper, as observed by our correspondent. The empty condition of these, and the specimens referred to immediately above, prevents one being able to trace out the insect author of the work.

(5) This bunch of eggs is the first stage of the only too well-known tent caterpillar (*Clisiocampa Americana*), to which we have often referred in this journal. Our correspondent will find a full description, with illustrations of the insect in all its stages, in Vol. I. of the CANADA FARMER, 1864, page 237; he will also find a notice of it in Vol. II., 1865, page 34.

The Red-humped Apple Tree Caterpillar.

"A Subscriber," writing from Whitfield, Township of Mulmur, has sent us some of the above-named caterpillars, which he states "are busy cutting the leaves off his apple trees," and asks for information respecting their "origin, name, and habits, and how to get rid of them."

Nearly two years ago (Oct. 1, 1866), we briefly noticed the occurrence of this insect at Sidney, Co. of Hastings, but we have not met with it since, nor have we even seen the parent moth; we hope, however, to raise some specimens from the larvæ before us, and thus know for ourselves, and not merely from others, the whole history of the insect. As it has now appeared in such widely distant localities as the Counties of Simcoe and Hastings, it will probably be found in other parts of the country, and may prove as troublesome as it often has in the neighbouring States. We are inclined to think, however, that it has found its way to the localities mentioned on some imported trees, like many other plagues of our orchards and gardens. Should this prove to be the case, it will furnish another argument for encouraging the many highly satisfactory nurserymen that we have in this country, and buying our fruit trees exclusively from them instead of procuring them from the neighbouring States.

We now proceed to describe the appearance of the insect, that our readers may be able to recognize it wherever it is met with. The specimens before us are about three-fourths of an inch in length, but when full-grown they attain to nearly double these size; their general colour is yellowish-red above and below, and white on the sides, with thirteen narrow black stripes (six on each side, and one on the middle of the back) extending from the head to the tenth segment, interrupted only on the fourth segment; there are also two rows of black prickles along the back, and a number of shorter ones on the sides, each of which terminates in a fine hair; the head is shining red, with black jaws; the fourth segment has a prominent hump of an orange-red colour, on which, as well as on the two preceding segments, the prickles are lengthened into spines; the eleventh and twelfth segments are entirely yellow, with the various prickles, but without any black lines; the last segment is black. The eggs from which these caterpillars are hatched, are laid, according to Harris, "in July, in clusters on the under side of a leaf, generally near

the end of a branch. When first hatched they eat only the substance of the under side of the leaf, leaving the skin of the upper side and all the veins untouched; but as they grow larger and stronger, they devour whole leaves from the point to the stalk, and go from leaf to leaf down the twigs and branches." When full fed, they leave the trees and form a cocoon under leaves upon or slightly under the earth, where they remain all winter, the moth coming out the following July. It is called *Edémasia* (*Nolodonta*) *concinna*, and was first described by Smith and Abbott in their work on the Insects of Georgia, where it is said to have two broods in a year. It is described as "a light brown moth, with its fore-wings dark brown on the inner, and grayish on the outer margin, with a dot near the middle, a spot near each angle, and several dark brown longitudinal streaks along the hind margin." It expands about an inch. In the accompanying illustration, fig. 1 shows the Caterpillar, and fig. 2, the perfect Moth.

The easiest way to destroy this pest would be to shake off the caterpillars, by a quick jarring blow on the limb, into a cloth or vessel below, and then put an end to their existence with hot water. When they are collected on a small branch, it might be cut off and burnt without any injury to the tree.

CURRANT WORMS.

The above correspondent also states that "there is a small green worm, about three-fourths of an inch long, busy cutting the leaves off the red currant bushes; it does not appear to touch the black ones. Please tell us how to get rid of them. I dusted slacked lime over them, which seemed to check them for a few days, but they were soon as bad as ever; they do not touch the fruit, but strip off the leaves and pass on." These insects are the larvæ of either the well-known Saw-fly or the Currant Moth; not having received specimens of them we cannot say which. The remedy that is now acknowledged to be best is a mixture of white hellebore, powdered fine, and alum in water; the worms should be well watered with this when they first appear, and from time to time as fresh broods come out; of course care should be taken not to use the mixture when the fruit is about to be gathered. Soot dusted upon the insects when the dew is upon them, and also placed upon the ground beneath, is highly recommended by one of our American exchanges, but we have not yet tried it ourselves.

The Squash Bug.

(*Coreus tristis.*)

To the Editor of THE CANADA FARMER.

SIR,—Enclosed you will find specimens of something, I know not what. But this I do know, it is committing fearful ravages on some mock-oranges and gourds which my wife planted for ornament. It is extremely prolific. It lays an egg very similar to that of a sheep tick, but not so large. The egg requires but a brief period to hatch. I believe it will live more than a week shut up in a box. I send a good supply because I have enough and to spare. The leaves it infests wither and die. I have killed it until I am sick of the sight, to say nothing of the smell. I find coal oil sufficient for it, provided it can be got on the thing. I should like to know its name, &c.

E. J. YORKE.

Wardsville, Ont

NOTE BY ED. C. F.—Mr. Yorke certainly did send us a good supply of specimens of the disgusting Squash Bug; the moment we opened the box, about a couple of dozen crawled out with tremendous activity, and we had no little ado to get them all disposed of again. Being only too familiar with the insect, and having no desire to re-introduce it into our garden, in which we succeeded in exterminating it, for the present, after a considerable period of warfare we speedily consigned these lively specimens to an ignominious fate. In last year's volume of the CANADA FARMER (June 1, page 173), we gave a short description of this insect. The remedies that we there prescribed were picking off and burning the leaves on which the bugs are collected, examining closely the under side of all the leaves of an affected vine, and destroying any eggs found attached to them, and watering with hot water. The means that we have since found most effectual are picking off the leaves on which eggs are deposited, crushing under foot all the mature bugs, and watering frequently with strong soap-suds. The surplus product—soap-suds—of that domestic nuisance "washing day" we always have kept for us during the gardening season, and find it most useful for destroying a large number of insects, such as these squash bugs, plant lice, slugs on rose-bushes, etc.; it is also a valuable manure for almost any kind of vegetables and vines. Mock oranges or gourds, as well as squashes, belong to the same family (*Cucurbitaceæ*) as melons, cucumbers, and pumpkins; while these bugs abound on the former, we are glad to say that we have never yet met with them on the latter most valuable plants.

Correspondence.

Wild Oats—Huron Crops.

A subscriber from Huron County sends us the following, which, though bearing date the 1st August, did not reach us till after the publication of our last issue. "How can a person escape having his farm filled with wild oats if they are in the neighbourhood? Is there any possible means of guarding against their introduction by travelling threshing machines, &c.? By indicating the precautions to be used you will greatly benefit many of your subscribers. The crops in this part of the country look very well, considering the terrible drought and heat which we have experienced. We are now, however (Aug. 1), having most refreshing showers. The early sown spring wheat will scarcely be worth cutting, being completely eaten out by the midge; the late sown wheat as yet promises well. I have also been informed that Platt's midge-proof, where sown early, has not proved exactly midge-proof. Fall wheat (midge-proof) has turned out fair, mostly, however, not a first-class sample. We hear great accounts of the Treadwell. Can it be got in any quantity, pure, and at a reasonable figure? Peas are shrivelled up with the heat—will be half a crop—but oats are probably fully average."

NOTE BY ED. C. F. The only means we can suggest for guarding against the introduction and spread of wild oats is to keep a strict and diligent watch, and pull them up by the roots in the early stage of their growth. They will make their appearance before any other crop, and can be readily distinguished even in a field of oats, by their colour, their ranker growth, and greater height above the surrounding plants.

STUMP MACHINE.—S. G., from Cashmere asks:—"Where can I get a horse-power stump machine, capable of lifting a two foot green oak stump; and what will be the price delivered at Bothwell Station, Great Western Railway? A screw preferred."

REFUSE FROM FLAX MILLS.—A subscriber asks, what is the best manner of utilizing the waste from flax mills for agricultural purposes; whether it should be rotted, and if so, what is the readiest and quickest mode of effecting this object. Can any of our readers give any practical directions in the case?

SEED WHEAT.—Mr. Isaac O'Neil, of Uxbridge, sends us a sample of wheat, which appears to be of good quality. It is a white wheat resembling Soules wheat. The writer says respecting it:—"I enclose you a sample of fall wheat, a quantity of which I have for sale—200 bushels. It is about ten days earlier than the Soules. It will yield thirty-five bushels to the acre this year. It is a new description, first obtained by finding a few heads in a large field. I have sown it for the last two years, and now have the above quantity. It is a white chaff, white wheat. Labour was very scarce this year, and I had to let it stand too long; otherwise it would have been brighter. The price is $2 per bushel. I reside one mile from Uxbridge Village, Ontario."

DÉCAY IN THE CROTCH.—BARREN BLOOMING.—A.T.G. writes to enquire "the cause of fruit trees (more particularly apple trees) decaying in the crotch and around the limbs. The trees are from eight to ten years old. Also, why some fruit trees continue blossoming during the summer instead of bearing fruit. I have some dwarf pears that are more ornamental than useful on that account." The decay in the fork of branches may be owing to some splitting of the wood in that situation, or to the wet and dirt that have accumulated there. Cleaning out the part and a coating of lime-wash might be useful in that case. In regard to the second query, some unhealthy condition of the tree is perhaps present, and possibly the drought and heat of the past summer, unfavourable to the proper development of the fruit, may have stimulated dormant buds into unnatural and premature growth. Without further information and personal inspection, we could not form a more definite opinion.

QUERIES.—A correspondent from Wardsville appends to a communication published elsewhere a miscellaneous collection of queries. In answer to some of them, we would inform him that the Secretary of the Provincial Association is Hugh Thomson, Esq., Ontario.—Amongst the successful breeders of Galloways in this Province are Messrs. R. L. Denison, Toronto; Wm. Wood, Guelph; Thomas McCrae, Guelph; and D. Youle, Stanley.—The ordinary horse bean would furnish the best meal for the purpose alluded to.—In reference to the Berkshire hog, it would be impossible to give an account of the numerous crosses from this breed—the principal foreign ones are those with the Chinese and Neapolitan swine, made with a view of decreasing the size of the animal, and improving the flavour of the flesh; and the animals thus obtained are superior to almost any other in their aptitude to fatten, but are very susceptible of cold from being almost entirely without hair. A cross of the Berkshire with the Suffolk and Norfolk pigs is also much approved in some quarters; a hardy kind is thus produced, which yields well when sent to the butcher; but even the advocates of this cross allow that, under most circumstances, the pure Berkshire is the best.

The Canada Farmer.

TORONTO, CANADA, SEPTEMBER 1, 1868.

The Season and Crops.

ALTHOUGH the persistency of the wide-spread drought from which the whole continent has so long suffered is at length broken, still comparatively dry weather continues to prevail in most parts of the Province. Occasional showers have visited every locality, but we do not hear of heavy or long continued falls of rain. Root crops, especially potatoes, are nearly everywhere needing moisture, and under any circumstances we must now look for a yield of those products below the average. The temperature has very greatly moderated, and the weather has been mostly fine and delightfully cool. Indeed it would scarcely be possible to have a pleasanter season than has prevailed during the greater part of the month of August. The returns of the harvested crops, so far as we can learn from local papers, are less unfavorable than the severe drought would have led us to anticipate. The results of threshing operations, which have been actively going forward, do not disappoint expectations, and in the case of fall wheat especially show a yield in excess of the returns of any recent year. We hear of crops that have turned out over forty bushels to the acre. The Soules wheat has suffered most from the midge, while the Treadwell and Diehl are both spoken of as having comparatively escaped the scourge, and yielding remarkably well. We expect that a large breadth of land will be sown with these varieties during the present month.

The importance of correct statistical returns in regard to our crops is becoming every year more apparent. We are glad to learn that the Minister of Agriculture for this Province, with a view of eliciting the desirable information, is issuing a circular and list of enquiries to the various agricultural societies of Ontario. If these enquiries are carefully answered by the parties addressed the department will be in possession of very valuable reports, the substance of which will, no doubt, in due time be given to the public. As this is the first year that any attempt of the kind has issued from this official quarter we cannot expect the returns to be so complete as they should be; but the effort is in the right direction, and will eventually secure, we trust, a yearly statistical report, complete and accurate, of the agriculture of the country.

The crop reports from the adjacent States, which appear to have suffered less from the drought than ourselves, are very encouraging; and if the published estimates are correct, the total yield of wheat will be considerably above that of 1867—indeed, some accounts say of any previous year. An Iowa Editor speaking of the harvest in that State, calls this the "golden year," and pictures the agricultural prosperity of the State in glowing terms. Perhaps some of this congratulatory tone of language and feeling may be the reaction from the fear and despondency which the severe and protracted drought had induced, and the test of the threshing machine may yet correct expectations that have been as much too sanguine as they were previously too doleful. There can be no doubt, however, that we have much cause for thankfulness in regard to the general character of the present harvest, and the result should rebuke the spirit of apprehension and discontent which farmers perhaps more than others are apt to indulge.

Seed Wheat Experimental Farm.

MR. George A. Deitz, of Chambersburg, Pennsylvania, is engaged in the important work of acclimating and testing foreign seed wheats. Since the appearance of his brief advertisement in our last issue, we have sent for and read with much interest his circular, which describes with considerable minuteness a number of varieties of seed wheat with which he has experimented successfully. We have always felt that this is a department of usefulness which properly belongs to Ministers and Boards of Agriculture, and we thoroughly believe that judiciously managed, as it might be under the supervision of a good practical farmer, the testing of foreign seeds might be made immensely beneficial to the agricultural interests of our own and other countries. In the absence of any such arrangement, it is gratifying to find that private enterprise is doing something in this direction. Mr. Deitz's circular contains details and illustrations of the heads of twenty-one varieties of wheat, that have been tested for from two to ten years, with mention of eight varieties only imported the present year, and therefore not yet tested on American soil. The account given of the several varieties appears candid and straightforward. We know nothing of Mr. Deitz beyond his advertisement and circular, but the importance of obtaining new and good seed wheat is so great, that we do not hesitate to recommend trial of the more promising sorts. It is not yet too late for any who are enterprising enough to experiment, to do so. We have sent for three varieties which, judging from the circular, we think most likely to give satisfaction in our soil and climate. They are the Benghton White, $5 per bushel; the Weeks' White Bearded, $6 per bushel; and the French White Chaff Mediterranean, $7.50 per bushel, American money. The prices are high, but there is much outlay and loss connected with the importing and trial of foreign seeds. In due time we shall give our readers the benefit of our opinion of these wheats.

PROVINCIAL EXHIBITION PRIZE LIST.—CORRECTION.—An error occurs in the above prize list which we are requested to notice and correct. In class 29, section 32, in the "General List" of Fruits, &c., for—"Best collection, not more than six varieties, Pears, correctly named, three of each," read—"not more than *twenty* varieties," &c.

Stray Notes of Travel in the United States.

[EDITORIAL CORRESPONDENCE.]

NEW YORK, Aug. 26, 1868.

WHAT you see when on a journey, or in a strange place, depends quite as much on your own eye as on the objects that are about you. This is true, not merely in a literal, but also in a metaphorical sense. The artist is on the look-out for scenes of beauty, the merchant has an eye to business, the politician studies the phases of public opinion, and the ladies keep a sharp watch of the fashions. An editor travels with his thoughts dwelling much on his next issue, and his eyes peering sharply around for the material of leading articles. If the journal about which he is anxious be general in its scope, he will have no difficulty, for topics will spring up on every hand. But if his journalistic sphere be a special one, his observations will be less fruitful. Still it will be a barren journey indeed, if it yield nothing to his purpose.

Railroads, it is well known, do not usually pass through the best portions of the farms they cross, and hence it would be hardly fair for an agricultural editor to judge the farming of a region by looking at it from the cars. Taking the evening train from Suspension bridge, there was but a short period of daylight in which to see things. It gave opportunity, however, to observe that Western New York has been passing through the same ordeal of heat and drought with which our own country has been afflicted. Long as the eye could distinguish objects, there was the same yellowness about the pastures and meadows, the same stunted vegetation, the same burnt-up look we had left behind us in Her Majesty's dominions. When morning dawned, however, a very different picture was presented. As our train neared Albany the corn fields on the Mohawk flats rose to view all fair, fresh, and green, as if no pinch of drought had touched them all the season. We saw once more, vegetation glistening with dew and rain, and the earth moist with showers. It was indeed a welcome and refreshing vision, and enabled me to realize, in a measure, how oriental travellers must feel when, after journeying for weeks over the desert, they gain at length the verdant valley of the Nile.

There cannot be a more delightful sail than that in the day-boat from Albany to New York, on the Hudson. This noble river has been not inaptly styled "the Rhine of America." Its ample bosom stretches from bank to bank, a mile or more in width, and on either side it is one panorama of natural and artificial beauty, the scene continually shifting, but always attractive and picturesque. Villas and gardens, towns and villages, wood-crowned heights, mountain ranges, and lovely intervales, diversify the landscape, while the river itself, winding along in stately majesty, and alive with all manner of craft, from the skiff up to the mammoth passenger steamer, is an object of tireless interest. The railway trains thundered along the river side, leaving our vessel far in their wake, though she nobly steamed away at fifteen knots an hour; but the day was only too short, and the trip too like an enchanting dream. As you near New York, many charming residences line the river, their ample grounds reaching to the brink of the stream, and the very boat-houses catching the contagion of the scenery and becoming tasteful, if not elegant. Commend us to a home on the Hudson, when we retire from active toil with an ample fortune!

After the day's charming sail, we passed the night (we were about to say slept) at lower Ravenswood, on East River, opposite Blackwell's Island, and never before listened to such a noisy insect concert as was kept up all the livelong night. Sleep was out of the question. We have been kept awake before this by in-door insects, but never until now, so far as we can recollect, by insects out-of-doors. Such an orchestra of stridulous music would, no doubt, have put our entomological confrere into ecstacies. We cannot say it had that effect on us. The Katydids were the noisiest of the choir, and weary enough we got of the constantly-threatened-to-be-told tale of what "Katy did," before morning. But though we never before heard so powerful an insect orchestra, it was thrown completely into the shade by the one that performed three nights afterwards at Athens, a village 100 miles up the Hudson, which we had occasion to visit. We have got a vastly enlarged idea of the vocal powers of the Cicada. But though it can be loud, it is far from pleasing, at least in our judgment. It may be, however, that our taste needs educating, duly to appreciate insect music. We thought of the ungallant couplet of old Aristophanes:

> "Happy the Cicadas' lives,
> For they all have voiceless wives;"

and wondered to what pitch of dissonance the domestic music would rise, if both sexes were but to perform their parts.

Many agricultural items may be picked up in New York, as we begin to find after a few days' sojourn in and near the city. It is interesting to visit the markets. Just now quite a panic exists in reference to diseased beef. Notwithstanding the utmost precaution on the part of the authorities, it is said that cattle affected by the Texas plague have been spirited to this city, and their carcases vended in the meat markets. Beef-steak, that favourite American dish, is quite out of repute, and, much against their will, the people are taking to mutton, for fear of being poisoned. Fowl are scarce, fish are hardly in season, eggs are dubious, butter is dear, and milk as well as beef may be spoiled by Texan fever; so that the question, what to eat, is not the easiest New Yorkers have to discuss just now. Happily the vegetables are wholesome, and there are plenty of them. The market-gardeners that supply New York have had no cause to complain of lack of rain the present season. If anything, they have had too much. How glad we should have been to relieve them of all they wanted to spare! Potatoes are a fine size here, and they seem to be abundant. Yet they are far from cheap;—two dollars a bushel, American currency. All vegetables bring a high price here, as compared with Canada. The fact is they are grown at immense cost, and must be dear. Land within market distance of New York is enormously expensive, and without the best of tillage and high prices, market gardening could not be profitably carried on. There are plenty of tomatoes, musk and water-melons, lima beans, and green corn in the New York markets just now. Sweet potatoes from the South, a much coveted luxury here, though in our view not to be named the same day with a mealy pink-eye, or Scotch kidney, are abundant, and go at the hotel tables in a galloping consumption. Fruit is scarce, and high in price. A single decent plum costs you three cents, and a good peach from eight to ten cents. Red Astracan apples are from three to five cents, and Bartlett pears as dear as the peaches.

Owing to the dry weather in Britain, the steamers from this port are taking novel freight across the Atlantic. Several shipments of hay, tightly baled, have been already sent, and more are to follow. Some of this hay that we have seen is rascally stuff, coarse, wiry, prairie and swamp grass, that will provoke from British farmers and shepherds curses loud and deep. Why cannot Canada do something in this trans-Atlantic hay trade? All that is wanted is pressing and baling machinery. The utter failure of hay and turnips in Britain, makes it certain that such an export business will be remunerative from now until next harvest. First-class machinery for pressing and baling can be had here, from R. H. Allen & Co., Water Street, New York, and others in the agricultural implement trade. By the way, an inspection of the Messrs. Allen's premises justifies all that we said when giving a synopsis of their voluminous catalogue in the CANADA FARMER some month since. It is a very complete establishment, and the implements are of first-class manufacture.

We spent five or six hours very pleasantly in Central Park yesterday. The purchase and laying out of this large tract of what was originally rough waste land, as a vast pleasure-ground, was a magnificent conception. Here are some nine hundred acres, that during the past ten years have been transformed from wilderness to Elysium. We are not sufficiently familiar with landscape gardening to venture the opinion that the plan of these grounds is the best imaginable, but as we surveyed them, we vainly tried to think of something that would be an improvement. There is nothing stiff or formal about the style of adornment that has been carried out. Winding paths, miscellaneously grouped trees, irregularly planted shrubs, and flowers that seem to have come where they are quite by accident; lakes here, fountains there, rustic seats and arbors yonder; rock-work, now on a limited scale, and now in mimic mountain grandeur; with a roomy carriage drive, nine miles in length, smooth and even as though shaped with a housewife's rolling-pin, gracefully curving here, there and everywhere—form a scene of natural and artificial beauty that must be seen to be appreciated. Here pedestrian Five Point poverty and wretchedness is as free to roam as mounted and equipped Fourth Avenue wealth and gayety. The varieties of character and condition to be seen here are quite a study. Beneath yon cozy little arbor that shades a seat just large enough for two, are a couple of lovers, telling and listening to "the old, old story" with which Cupid charms his votaries. There on a rise of ground, seated on one of several seats in a larger rustic edifice, is a pale-faced student with book in hand, drinking in health and knowledge at once. Near him, on another seat, is an aged and spectacled man reading a magazine. A little farther, a care-worn woman with a babe in arms, and another little one by her side. Yonder in a single-seated lonely recess, is a sorrowful young creature, who looks as if she had grown weary of life and were debating whether or no to renounce all this beauty, and "rashly importunate" go to her death. Fast young men lounge here and there, with misses to match them not far off. But the diversity is well-nigh endless. New York may pour out its millions, and these avenues, walks, arbors, grottoes, terraces and seats will not be crowded. The lake is a curiosity. This whole formation is rocky. Here and there natural rock-work shows itself and gives great boldness to the scene. To form the lake-bed, the rock has been blasted fully a mile in extent, but not all in one large area. There are straits, channels, points, promontories and islands. A fleet of twenty-seven boats equip this lake for voyaging, and for ten cents you may have a sail from end to end of it. Swans of large size and magnificent plumage float on the bosom of the water, and add much to the beauty of the scene. At the upper part of the park you find the highest point. There, on a rocky eminence of considerable elevation, you may see on the one hand Croton reservoir, and on the other New York itself, which owes so much to that reservoir. Croton water and Central Park are fountains of health to this great city, with which it could not well dispense.

But this letter, already quite long enough, must close, leaving us lingering in the loveliest spot we have seen since leaving home. You too, gentle reader, would feel like lingering in Central Park, were you in it, we can tell you.

VICK'S ILLUSTRATED CATALOGUE OF BULBS.—We have received a copy of Vick's Catalogue of Bulbs for the present autumn. The list is full, and accompanied with clear and simple directions for the culture of the several varieties. The name of Mr. James Vick, of Rochester, N. Y., is sufficient guarantee for the excellence of any article advertised by him in this department of Horticulture.

The Texas Cattle Disease.

THE alarm, amounting to panic, caused by the fatal disease introduced into Illinois, Indiana, and some of the Eastern stock yards, by Texas cattle, has in a measure subsided, not on account of the discovery of any exaggeration in the reports of losses sustained, or the virulence of the complaint, but chiefly from the apparent facility with which the spread of the disease can be prevented. It would appear that Texas cattle alone are capable of communicating the disease, and that native cattle, though fatally afflicted themselves, do not transmit the virus to others. It is believed also that only during certain limited periods of the year is there any danger from the disorder. If these statements are correct, it is probable that by regulating the periods at which Texas cattle may be introduced, by a system of inspection and quarantine, and by isolating the droves in transitu, the future ravages of this terrible scourge may be guarded against.

There is every reason to believe that hitherto we have ourselves escaped the pest. The Canadian Government and the Board of Agriculture have acted in the matter with praiseworthy promptitude. By an order in Council the transit of Western cattle through the Province has been interdicted. A special meeting of the Board of Agrienlture was convened to take the subject into consideration, and the following resolution, among others, was passed:—"That a Committee, consisting of the President of the Board of Agriculture, the President of the Association, Dr. Richmond and Mr. Stone, oe appointed to examine into the cattle disease, and report at as early a day as possible; and that Professor Smith, of the Veterinary College, Toronto, be appointed to accompany them." The gentlemen named in the above resolution accordingly proceeded at once to Chicago, intending thence to visit other localities where the disease had been most prevalent, and institute a thorough investigation. Up to the present date, Aug. 28th, they have not returned, though we have been waiting in the hope of being ablo to communicate their report in the present number of this journal. This must now be deferred till our next issne. By that time also the report of the Commissioner whom the Government has appointed to investigate the matter will no doubt be made public.

Since the above was in type the Deputation from the Board of Agriculture have returned, and Mr. Smith informs us that it will yet be some days before they can complete their official report. In the meantime we may briefly state that they found the complaint on the decrease in Illinois, partly because in some places a large proportion of the native cattle had died—in Champaign County upwards of 4,000 have perished—and also in consequence of the restrictions now in force in regard to Texas cattle. Mr. Smith thinks the prevailing opinion that native cattle will not communicate the disease should be received with caution; that time and further experience are yet needed to determine this point, as well as much more respecting the precise nature of the disease. It has made its appearance in Kansas, also in St. Louis and Sullivan, in Missouri, and in Cincinnati. Under all the circumstances the Deputation are of opinion that it will not be wise to relax the interdict ngainst the admission of Western cattle into Canada.

The Provincial Exhibition.

THE Provincial Exhibition at Hamilton this year promises, in the number of entries, to be fully equal to any of its predecessors. The condition of the crops is looked on as a circumstance favouring a good show, and the entries of grains, especially wheat, have been above the average. As the entries are not all made, and a large number of those sent in have yet to be recorded, no figures to show the aggregate in each class can be had, and it will be close on the Fair week before a correct estimate can be made.

The entries for live stock closed on the 25th ult., but as all have not yet been registered, we cannot give the exact figures. "In the classes of horses, cattle and sheep, there will be a large exhibition, the show of pigs will be below the average in number, while that of fowls will probably be very numerous. On the whole, there is every reason to expect a large and, we doubt not, a creditablo and successful Exhibition.

Book Notice.

A GUIDE TO THE STUDY OF INSECTS, AND A TREATISE ON THOSE INJURIOUS AND BENEFICIAL TO CROPS.—For the use of Colleges, Farm Schools, and Agriculturists. By A. S. Packard, Jr., M. D., Salem. Press of the Essex Institute. Part II., July 1868. Price 50 cents.

The second part of this valuable work is now before us, and we desire again to cordially recommend it to the attention of our readers. The present portion of the work consists of sixty-eight pages, clearly printed on fine smooth paper, and illustrated by about fifteen wood-cuts, and two full-page plates carefully and accurately executed. It gives first the conclusion of the account of the strange and marvellous transformations of insects throughout their life, from the egg to the winged imago; then follows an outline of their geographical distribution, including a notice of variation of species produced by climate, soil and food, and the remarkable fecundity possessed by noxious insects accidentally introduced into this continent from Europe, of which the wheat-midge and currant-bush saw-fly are notable instances. A somewhat kindred subject, their geological distribution, is next taken up, and notices, accompanied by illustrations, are given of many singular fossil specimens that have been discovered in the coal measures of Nova Scotia, New Brunswick and other carboniferous districts. When the delicate fragile structure of insects is considered, it is very wonderful to find how many specimens have been obtained from the solid rock. The diseases and deformities of insects, a branch of entomology that has been seldom investigated, are briefly noticed; then follows a most useful and valnable account of the best modes of collecting, preserving, and rearing insects, which we would strongly recommend to the attention of all insect collectors; a useful list of the most important works on entomology, and tables of the various modes in which insects have been classified by authors, complete the preliminary portion of the work. A systematic account of the various orders of insects is then begun,—the order Hymenoptera, which includes bees, wasps, ichneumons, saw-flies, etc., being first taken up, as holding the first and highest rank in the insect series. This part of the work well deserves the careful perusal of all interested in the habits and works of bees and their enemies, and therefore ought to be in the hands of every bee-keeper in the country. Of the whole work, judging from the two parts now issued, we may say that it furnishes to beginners in entomology a manual of directions superior to any that we have ever before met with, while to the more advanced student it affords a convenient and useful book of reference.

PRIZE LISTS.—We have received, amongst other documents of a similar nature, the list of premiums for the forthcomiog Agricultural Exhibition of the New York State Agricultural Society, and also that of the Michigan State Agricultural Society. The former of these, as already announced, will be held in Rochester, from the 29th September to the 2nd October inclusive; and the latter in Detroit, from September 15th to the 18th—the weeks preceding and following the Provincial Exhibition at Hamilton. The premium lists embrace all the usual departments, and are on a liberal scale. Additional prizes are also offered for the best crops of various kinds, and for the best essays and reports of experiments on certain specified subjects. The directors of the New York Society wish especial attention to be directed to their new regulation requiring that all entries of cattle, horses, sheep, swine, poultry, and machinery should be made at least two weeks before the fair.

SELL'S CIDER MILL.—We direct attention to Mr. Sell's advertisement of Cider Mills, in the present issne. These well-made and thoroughly efficient presses have gained distinction wherever they have been exhibited, and have given entire satisfaction to those who have used them.

MUSKOKA SETTLER'S GUIDE.—We have received a small sheet bearing this title, and published by the Muskoka District Settlers' Association. We presume it is intended to follow up this first number by others from time to time, as matter accumulates and occasion requires. The present number is chiefly occupied with an account of the origin, objects, history and recent meeting of the Association. It contains the President's address, and a paper on the district of "Muskoka as a field for settlement," full of valuable and interesting details, given apparently in an honest and impartial spirit. We commend the example and efforts of the Association to disseminate trustworthy information concerning a region hitherto little known, and very sparsely settled, but offering by all accounts many inducements to the hardy and enterprising emigrant.

Agricultural Intelligence.

Show at Aberdeen of the Highland Society.

To the Editor of THE CANADA FARMER:

SIR,—The forty-first exhibition of this venerable society, which may be regarded as the parent of all British agricultural societies, is just concluded. The good old "granite city" has been full to repletion, and everything appears to have been done that was practicable, both by the directors of the society and the citizens generally, to accommodate visitors and make the occasion what it has proved, a great success

I may just state for the information of some of your readers that the "Highland Society" was first established by royal charter as far back as 1787, and that its sphere was confined to the more alpine districts of Scotland, as its name denotes. For many years previous a society had existed in Edinburgh for the improvement of land, consisting mainly of the great landholders; but it does not appear that this society attracted much public notice; yet it published its transactions and unquestionably led the way for the formation of the Highland Society. As, by degrees, it became apparent that the Society's operations should not, and in strict practice were not, exclusively confined to the Highlands, an amended charter was obtained in 1834, and the name of the society thenceforward has been known as "The Highland and Agricultural Society of Scotland." Under its enlarged charter the Society has not only sustained in a spiritod and liberal manner a yearly show of stock and implements, but devoted periodically a large amount of funds to the preparation and publication, by way of premiums, of essays and reports on the theory and practice of husbandry in all its various applications. It was also, I believe, the first British Agricultural Society that engaged the services of a Professor of Chemistry; the late Professor Johnston had the first appointment, who was succeeded by the present accomplished chemist, Professor Anderson. The society also gives aid to local shows, and has of late encouraged the study of the science and practice of agriculture by awarding diplomas to young men, who undergo satisfactorily certain courses of examination. In this way the society has been able to obtain most valuable materials for publication, and the large number of volumes in its transactions shows the talent and liberality with which its proceedings have so long been conducted.

The only thing worth mentioning that I have heard of, disadvantageous to the present show, arose from some unfortunate misunderstanding between the exhibitors of Clydesdale horses and Argyleshire cattle

in the vicinity of Glasgow and the railway managers, relative to the transport of the same to and from Aberdeen. The consequence was that these important classes were but very indifferently represented here; and a show was got up in Glasgow on one of the same days as the Highland; a circumstance liable to an unfavourable interpretation, and in every way deeply to be regretted. I am informed by a gentleman who was present that quite a number of animals of very excellent quality was got together at Glasgow, and prizes awarded of equal value to those of the national society. Considering this drawback and the character of the season, the Aberdeen show must be regarded by its friends and patrons with no small degree of satisfaction, if not of pride. About fifteen acres of the "Links," a large undulating space between the city and the sea, were walled in, and it was found only just large enough to comfortably accommodate exhibitors and visitors. The judging commenced on Tuesday morning, and was got through with by two in the afternoon. The public were admitted during the period of judging on the payment of ten shillings; the remainder of the day and the next day, the fee was reduced to half a crown, and to one shilling on the third and last day. By these arrangements there was no overcrowding, and all classes had an opportunity of inspecting comfortably and fully each department of the show.

I could not, perhaps, give your readers so adequate an idea of the exhibition as by stating the aggregate number of animals entered in each class:—

Short-horn Bulls	42
" Cows	30
" Heifers	48
Aberdeen or Angus Polled Bulls	40
" " Cows	21
" " Heifers	25
" " Oxen	9
Galloways, Polled Bulls	7
" " Cows	4
" " Heifers	11
West Highland Bulls	14
" " Cows	17
" " Heifers	20
" " Oxen	9
Ayrshire Bulls	8
" Heifers	8
" Dairy Cows	17
" Fat Oxen	24
" Fat Heifers	11
" Crosses	8
Total	373
Horses	139
Sheep	832
Swine	57
Poultry	480
Grand total	1881

The number of machines and implements, and other articles included in that department, amounted to 1158. As the exhibition was open to competitors from all parts of the United Kingdom, the implement department comprised seventy-eight Scotch, twenty-six English, and two Irish exhibitors; making a total of 106. The number of exhibitors in the live stock departments was 285, and these, with very few exceptions, were Scotch. The distance of Aberdeen, coupled with the fact of the show being held so soon after that at Leicester, will sufficiently account for the small number of English exhibitors.

In a communication of this kind space will not admit of many particulars, most of which would not possess much, if any, interest to your readers. The Short-horns were not only comparatively numerous, but of excellent quality; the bulls particularly, it was said, had never been excelled. Mr. Cruikshank, of Sittyton, in this county, who it is said has the most extensive herd of Short-horns in the United Kingdom, exhibited a splendid old bull, "Forth," the finest handler I ever met with,—though I heard it stated by several parties who had watched his career, that his symmetry was less perfect than formerly, and that high feeding and preparing for shows had produced a deteriorating effect upon him, as it has often done on too many of our choicest animals. Mr. Barclay's fine bull, "Heir of Englishman," which I saw at Leicester, where it attracted general attention and received from the judges a "highly commended," here obtained the first prize. The two-year old bulls, as a class, perhaps were not in point of symmetry equal to the aged class; Mr. Cruikshanks' "Grand Prince" was placed first, and a finer looking animal one seldom sees. The yearling bulls were unexceptionably good. Of the cows and heifers it may be said, with some few exceptions, that they contained specimens rarely excelled—all the leading points well and harmoniously developed, that characterize the modern Short-horn. Mr. Ainslie's "Thistledown," two years, a faultless animal, won the first prize. Several eminent Short-horn breeders in the Lothians were absent; but the young stock in particular was of a high character, indicating progress in the future.

The Polled Angus, or Aberdeen, was after all the breed that gave a decided character to the show. All I can say myself, not having any experience of this breed, is that they are very beautiful animals, having the expression and points that indicate a distinct type. Those who have a practical knowledge of the breed spoke of the specimens exhibited as surpassing all former occasions. In this north-eastern section the Polled Angus has for many years received special attention, and here, if anywhere, perfection, or something approaching it, may be reasonably looked for. Mr. McCrombie, of Tillyfour, whose farm I hope to have the pleasure of inspecting before leaving the country, took a prominent position in this class; his herd is thought to be unsurpassed, both as regards extent and character. The Polled Galloways did not muster in great numbers, and as a class were considered to fall below the Angus, yet there were some very fine specimens of this valuable breed. To the ordinary observer the Angus and Galloway will appear almost identically the same, but the practical eye detects the difference. The former usually attain a greater size, have a less shaggy coat, and are better adapted to a dry climate, like that of the east coast of Scotland. The Galloway is found well suited to the soils and climate of Canada; few have yet tried the Angus, which I have little doubt would be found to endure our dry cold of winter very well. As beef cattle, both breeds are held in very high reputation in Britain, and command high prices.

I naturally felt much interest in the Highland class, a type of animal so very different to the larger breeds one has all along been accustomed to. The West Highlanders, I was assured by competent judges, were quite up to the mark, and they certainly have all the characteristics of a distinct breed, specially adapted to the soil, climate and exposure of the bleak and mountainous parts of the country. The Duke of Athol showed several beautiful specimens, as also did others of less note. As the beef of this hardy race fetches from eight pence to ten pence a stone more than that of the larger breeds, in London and other great markets, more attention has of late years been paid by hill farmers to the breeding, feeding and protection (at least to some extent) of the Highland cattle; the consequences are greater size, earlier maturity, and a more thorough intermixture of fat and lean in the flesh, which becomes thereby greatly improved.

The Ayrshires, for reasons already stated, were poorly represented. There were a few specimens of decidedly superior animals, denoting strict attention to breeding and good management. In Canada they would be considered rather small. While looking at this class, I accidentally fell in with Mr. Laurie, of Scarborough, Ontario, who was inspecting the show yard with a view to procuring something to take back with him. All really good animals for breeding, whether horses, cattle, sheep, or swine, are held at very high prices.

I was not prepared, especially during such hot weather, to find so large and good a display of fat cattle. The Short-horn in weight certainly excelled but the Polled Angus came well up to it, and finer animals one need not care to see. The Short-horn bull is commonly employed to cross with the Polled, and even the West Highlanders, and the result is, I am informed, very satisfactory; for slaughter of course not for breeding from. Not a single specimen of a Devon or Hereford was on exhibition, these breeds being hardly known in Scotland.

The show of horses was not equal to former years, mostly in consequence of the large number of Clydesdales from the south-west not putting in an appearance. The cart horses would be considered too heavy in Canada, though some, both mares and stallions, evinced good action in connection with great muscular power. The truth is, heavy horses are only suited for drawing great weights at a certain and comparatively slow pace, and to combine the two opposite conditions of great weight and quickness of action in the same animal is physically impossible. There were some good specimens of thorough-breds, roadsters and ponies; some of the former seemed excellently adapted for breeding saddle and carriage horses. As the roads in the United Kingdom have of late years been brought into so smooth and perfect a state, carriages of all descriptions have become lighter than formerly, and consequently horses for locomotive purposes are less massy.

The display of sheep was not so extensive as I had expected, particularly in the mountain breeds. The Leicesters, on the whole, were decidedly good, the best it is said that have ever been seen north of the Tay. The few Southdowns exhibited indicated a coarseness not pleasing to a Southern eye. They were, no doubt, large and strong constitutioned animals, well adapted perhaps to the situations in which they were located. The Shropshire Downs were good, and this useful breed seems to be extending in every direction. Both the Cheviots and black-faced sheep were very limited in number, a fault which their superior quality, in great measure, made up. The heather sheep of the mountains I regard as the prettiest specimen that can be found among the various British breeds, and their practical management among the hills and narrow valleys of the Highlands is a most interesting study to a lowland farmer. Their flesh is peculiarly delicate, and commands the highest price. These sheep, like the West Highland cattle, have been much improved of late years by more attention being paid to breeding, feeding and shelter; though yet, I am told, it continues widely the practice to let them in great measure forago for and take care of themselves.

The swine department was also restricted as regards number, which I am told is usually the case in most of the Scottish shows. For quality, however, I never saw better anywhere. Mr. Duckering, of Lincolnshire, and Mr. Findley, of Glasgow, with others that could be mentioned, exhibited a number of animals that could not well be excelled.

In poultry the competition was not great, but there were specimens of high merit in several of the breeds. Some of the ducks were superior, and the Grey Dorking was represented, and is, I should infer, a favourite barnyard fowl in Scotland.

The implement department was much larger than at any show heretofore so far north. The articles were in great measure precisely the same as were shown in very much greater number at the recent English show at Leicester. Fowler's traction engine and ploughing apparatus was exhibited by a Kincardine Company. The machinery was put in motion, but there was no opportunity of doing real work, nor any testing of implements in the field.

At these national shows no grains, fruits, &c., are exhibited; a want that has very long been felt has been partially met, both in England and Scotland, by holding an horticultural exhibition during the same time and adjoining the show yard of the agricultural show. The Royal Horticultural Society of Aberdeen accordingly held a very successful show of flowers and fruits in a capacious tent, and wooden shedding. I was not prepared to see so extensive and fine a display in the various branches of horticulture. The floral tent had a magnificent appearance, and the vegetables and fruits, considering the unfavorable character of the season, were really excellent. Late

strawberries were of large size and rich in quality, having a peculiarly pleasant acid flavour. The gooseberries were the finest I ever saw, and the other small fruits were of excellent quality. This part of Scotland is renowned for its gooseberries and strawberries, and yearly sends large quantities of plants to various parts of the world. The pine-apples, grapes, peaches, nectarines, and other hot-house fruits, were splendid; indicating in an unmistakable manner that the Scottish gardener, as well as farmer, has attained to an advanced position both at home and abroad. I have just learnt that the total receipts at the gates of the agricultural show were £1,576, and the amount of prizes offered £1,000.

The excessive heat which has for many weeks prevailed seems now somewhat abated. Showers have more or less fallen in various places in the United Kingdom, and their effects have doubtless been locally beneficial. It may still, however, be said that the drought continues, with no immediate prospect of a permanent change. Water universally is getting scarce, and in some localities it can be obtained only in the smallest quantity. In such situations cattle are suffering as much, if not more, on that account than from want of keep. Pastures being dried up, farmers have to give their cattle and sheep large quantities of grain, oil cake, and other artificial food; even, in some places, the dwarfed spring grain has been cut and devoted to that purpose. Considering all these disadvantageous circumstances, it is really surprising to find stock doing so well as is actually the case. The greatest suffering has been among young lambs, from the want of a sufficiency of milk; many ewes soon after lambing having gone nearly dry. I have been surprised to find in various parts of the country how well sheep have done where they could get anything in moderation to eat; and on the richer pastures, although apparently nearly burnt up, the animals have actually got fat. What is now wanting to save the stock is a succession of heavy showers, and the possibility is that pasturage will be abundant during the later portion of autumn and the earlier part of winter.

In the central and southern parts of England the harvest is fast drawing to a conclusion; and here in the northern parts of Scotland it has on the earlier soils commenced. This is almost unprecedented in the annals of British agriculture. Wheat is the only good crop that the British Islands will this year produce, and this remark will more or less apply to many portions of the European continent. The price of wheat is rapidly falling, but I do not, after all, anticipate very low terms for that indispensable article. Spring grain generally must be very deficient, and will command high rates. In this part of the kingdom oats and barley are extensively cultivated, and where got in early, in good condition, on the richer and cooler class of soils, these crops are very fair, but in general they are miserably bad. What with the inferior grain crops and the great reduction in the price of all kinds of stock, this must prove a very losing year to the British farmer. I am glad to hear such good accounts of the crops in Canada, and our farmers will find on this side a brisk market for their surplus spring grain. Of the potato disease I hear not a word, the drought seems to have annihilated it, at least for the present, but the crop, as also that of turnips, mangels, &c., must be very light. I shall return to the Lothians through the Western Highlands, having received several invitations from hill farmers, whose systems of management will be new to me, and no doubt suggestive and interesting. I have as yet been uniformly received in a friendly manner, and find the people generally well disposed to hear information on matters relating to Canada. Of the anti-colonial feeling, I have as yet seen scarcely a trace of the existence.

GEO. BUCKLAND.

Aberdeen, August 3rd, 1868.

The Crops in the United States.

THE Associated Press of the United States have received reports from almost all parts of that country regarding the harvest. We give them below condensed:—

WHEAT—This crop is larger than last year in West Virginia, Indiana, Ohio, Missouri, Kansas, Utah, Colorado, Montana, Illinois, Iowa, Wisconsin, Minnesota, New York, Pennsylvania, New Jersey, Maine, Massachussetts, Connecticut, and New Hampshire, and the quality is regarded as excellent. In Georgia, South Carolina, Alabama and Texas, the reports are not so good, the yield being indifferent. In Louisiana, Arkansas, Kentucky, Mississippi, Maryland, South Western Virginia, Central Tennessee, North Carolina, Delaware, and Vermont, the crop has been an average one.

CORN—From all sections of the country this crop is very large, and quality remarkably good. The yield this year promises to be fully one-third more than last. This is especially true of the Southern States.

OATS—In Kentucky, Tennessee, West Virginia, Indiana, Missouri, Kansas, Ohio, Nebraska, Iowa, Wisconsin, Minnesota, Vermont, New York, and Illinois, (especially in the latter States), the yield is large, while in Louisiana, Mississippi, Georgia, Florida, South Carolina, and the other Southern States, it will not be more than an average. Late rains have injured the crops in New Jersey, Pennsylvania, Delaware, Maryland, and Maine, and the yield in these States will be less than usual.

BARLEY—Will be an average crop.

HAY—More than the average crop will be realized. In Pennsylvania, New York, Indiana, Ohio, New Jersey, Delaware, and Maryland, the yield is very large and of excellent quality.

The potato crop is generally large and good. A heavy mildew and insects have killed hops in Pennsylvania.

The Drought in England.

THE long continued dry weather in England is causing the export from America of an article which we rather think for the first time crosses the Atlantic in any noticeable quantity. Five steamers—the "Colorado," "City of London," "City of New York," "Erin," and "Louisiana,"—have all within a week left New York, freighted with hay for the British market; and all the steamers for a fortnight ahead are bespoken for the same cargo to their utmost capacity. If rains do not come speedily in Britain this must go on for the season. Already hay is commanding very high prices in the interior of England. It is calculated that the sheep alone require as much as 54,000 tons a day; and they are in many districts being fed as much as in the midst of a snow storm in the depth of winter. To what extent this want may be supplied from the continent of Europe of course cannot as yet be determined; but the fact of hay being already exported from America, and at such a price as amply to repay the trouble and expense, gives us a new idea of the extent and severity of the drought. It is not too late yet, if rain in abundance should come speedily, to have the pastures revived, but up to the 6th of August, at any rate, there seems to have been no change, such as all must be anxiously looking for.

Growth of an Australian Colony

ALTHOUGH the first rush to the new Australian colony of Queensland, which was erected as an independent settlement on the 10th of December, 1859, met with some check in 1866, and the country seems also to have been subjected to drawbacks from the fact that the settlers are such as usually throng to a new district—about five per cent. of the entire population being annually taken into custody—the progress of the colony has been remarkable. According to a despatch from the Governor, Sir G. F. Browen, just published, the European population since the date of its establishment has increased from less than 25,000 to nearly 100,000; while the revenue and the trade, including exports and imports, have been almost trebled. The other chief elements of prosperity have advanced in a nearly equal proportion. During the same seven years cotton and sugar have been added to the list of staple products; a line of new ports has been opened along the eastern seaboard from Keppel Bay to Cape Cork, a distance of 1,000 miles; and settlements have been formed around the head of the Gulf of Carpentaria on the northern coast of the Australian continent and a distance of more than 1,500 miles from the seat of government at Bresbane. Moreover, during the same period, pastoral occupation has spread over the greater portion of the interior of Queensland; that is, over an additional area at least four times larger than the area of the United Kingdom. In 1859 the pioneer settlers had scarcely advanced beyond the Darling Downs to the west, or beyond Buckhampton to the north. Now there are stations more than 700 miles to the north and north-west of Buckhampton.

☞ A new variety of corn, the result of selecting seed and of high culture, has originated in Minnesota. The yield last year was as high as 127 bushels to the acre.

American State Fairs.

THE following is a list of the principal American State Fairs, with the days on which they will respectively be held.

New England	New Haven, Ct	Sept. 1— 5
Kentucky	Louisville	Sept. 8—12
Vermont	Burlington	Sept. 8—11
Michigan	Detroit	Sept. 15—18
New Hampshire	Manchester	Sept. 15—18
Ohio	Toledo	Sept. 21—25
Illinois	Quincy	Sept. 21—26
Iowa	Clinton and Lyons	Sept. 29—Oct. 2
Indiana	Indianapolis	Sept. 28—Oct. 3
Wisconsin	Madison	Sept. 29—Oct. 2
Minnesota	Minneapolis	Sept. 29—Oct. 2
Pennsylvania	Harrisburg	Sept. 29—Oct. 2
New York	Rochester	Sept. 29—Oct. 2
Maine	Portland	Sept. 23—Oct. 2
New Jersey	Waverley	Sept. 29—Oct. 2
Colorado	Denver City	Sept. 29—Oct. 3
Kansas	Leavenworth	Sept. 29—Oct. 2
Missouri	St. Louis	Oct. 5—10.

HORTICULTURAL FAIRS.

Am. W. G. Association.	Cincinnati	Sept. 22—
N. Y. Grape Growers.	Canandaigua	Oct. 7—8

ENGLISH CROPS—The *Agricultural Gazette* furnishes the following tabular statement of over two hundred returns of this year's crops from various localities in England, which show wheat and peas to have been considerably over the average of previous years, while other crops have been mostly below the average:

	Total.				Percentage.		
	Average.	Under Average.	Over Average.	Total	Average.	Under Average.	Over Average.
Wheat	67	13	126	206	32	7	61
Barley	54	140	5	199	27	70	3
Oats	37	138	2	177	19	80	1
Peas	55	8	52	145	58	6	36
Beans	22	137	0	159	17	83	0
Root crops	9	102	0	95	9	95	0
Potatoes	93	101	4	198	32	46	2
Hay	22	180	2	204	12	88	0

☞ A letter from Denmark describes the heat in that country as most intense. The wheat and rye are good, but all other crops are failures. The prospects of the cattle trade are indifferent. *Farmer* (Scottish).

☞ A large trade in the importation of wheat from California is going on at New York. Eighty-nine vessels are said to be on their way from San Francisco to that city at present, loaded with cargoes of wheat aggregating about five millions of bushels.

FALL SHOWS.—The annual exhibition of Addington Agricultural Society, will be held at Newburgh, on Thursday, the 15th day of October next. The township of Camden Show will be held on Saturday, the 10th day of October next, at Centreville.

THE WOOL MANUFACTURERS' CONVENTION met in Chicago, on the 5th of August, under very favorable auspices. The display of woollen goods, including cloth, jeans, shawls, blankets, flannels, yarns, knit goods, &c., was very good indeed. The wool-growers, with few exceptions, seem to have given this exposition the cold shoulder. The states of Illinois, Indiana, Iowa, Wisconsin, Michigan, Ohio, Kentucky, New York, Rhode Island, Massachussetts, Pennsylvania and Connecticut were represented. Gov. Oglesby, of Illinois; Mayor Rice, of Chicago; Hon. J. B. Grinnell, and other distinguished gentlemen addressed the Convention.

THE PARIS EXPOSITION.—The honours awarded to exhibitors from this Province, at the International Exhibition last year in Paris, have been received by the Secretary of the Provincial Agricultural Association and distributed to their owners. The diplomas accompanying the medals are now gracing the shop windows in more than one place through the city, the possessors evidently attaching some value to their mark of pre-eminence. Recently we were shown a bronze medal awarded to Mr. Francis Barclay of Innisfil, for a sample of wheat, the same wheat which took the Canada Company's Prize here in 1866. The ornament is naturally very much prized by its owner, and although not the highest awarded, still reminds us that Canada can stand comparison with wealthier communities in the staple product.

Hybridizing and Crossing the Grape.

A REPORT FOR THE DIRECTORS OF THE FRUIT GROWERS' ASSOCIATION OF CANADA.

GENTLEMEN.—There is no practice more fascinating and instructive in the whole range of horticultural experience, than that of producing new varieties of fruits by the art of hybridizing. It brings the operator into very intimate relation with those laws which govern the production of new *being*. He learns that nature, in her great laboratory, contains unlimited material for the developement of man's skill; it makes him comprehend that beautiful liturgical expression,—"As it was in the beginning, is now, and ever shall be." He sees the strongest analogy between the vegetable and animal kingdoms; he acknowledges, with a subdued spirit, the harmonious relation of forces; and with a thoughtful, inward, voluntary praise, worships the AUTHOR.

That the mode of operation may be clearly understood, he should examine the flowers of the grape at different stages of development with the microscope. He will see that the whole cluster contains many distinct flowers, each one of which is capable of self-fertilization, and has a cap composed of five petals cohering, which is raised up and thrown off by five expanding stamens contained within the cap; each stamen holds a small cup, called an anther, at its summit, containing the pollen, or male essence, beautifully surrounding the stigma, the terminal point of the pistil or female organ—the crown of the fruit in embryo; this apex contains a viscid substance to which the pollen adheres when brought in contact by the air or insects; when the grains of pollen lodge here they cannot get away, they penetrate and are absorbed by the stigma, and pass down through the pistil to the ovules or undeveloped seed. These beautiful organs, so suitably adapted to an intelligent end, command our attention. The process of fertilization goes on without our assistance; and it is a startling fact that in a short period the compass of this earth would not be sufficient to contain the reproductive force of a single species, were there favorable conditions to sustain the life of every germ.

When we wish to produce a new variety, by crossing, we place the pollen of one variety upon the stigma of another. Let me proceed to explain intelligibly how the whole process is performed. The operator must secure a magnifying glass, efficiently powerful to see each separate grain of pollen; a delicate pair of pincers and scissors; a camel's hair pencil; a very small clean and dry vial, with a large neck; a sheet of white, smooth, glazed paper; a thin paper bag to enclose the cluster when finished; and a label to mark the parentage. He must then on a clear dry day take the glazed paper, and with it surround as many clusters as required of any desired kind, in full flower, when scattering their pollens bounteously; snap the paper several times with the finger, it will then contain the pollen; open it carefully, gather the powder with the pencil, twirl it in the vial, and thus proceed until he have sufficient; then cork tight and put in a dark, cool place, labeled for future use. It is necessary that the flowers to be fertilized should be the last to bloom; when these are ready, which will be indicated by some of the caps being thrown off, then, with the scissors, remove two-thirds of the flowers in the cluster, with those already opened, and from the balance, with the delicate pincers, gently remove the caps; this any one will be able to do by a little skilful practice without injury to the stigma. Cut away the stamens, with their anthers, and with the magnifier observe the viscid surface of the stigma; should there be one with a grain of pollen adhering, cut it off; if not, take the hair pencil, introduce it in the vial, great quantities of pollen will adhere, place it upon the viscid stigma of each. Take the glass again and look; if the points are covered with pollen the work is good; inclose the cluster in the paper bag, tie the mouth and label it with the parent's names; this should all be done in the morning, after the dew is gone; let the bag remain till the surrounding flowers have set their fruit and commenced growing—so as to avoid insects and stray pollen. This practice with the grape will enable the hybridizer to operate with other flowers and fruits; but he must always bear in mind that the success of this undertaking depends much upon the proper selection of the most suitable parents for a desired result; this will always be open to the judgment of each operator; and also that beside the variations of seasons, the different modes of cultivation will perpetually produce varied results. For these reasons I would recommend all those who are trying their hands in this direction, to continue their operations from season to season. It will be found also, in the course of practice, that the difference in sexual conformation prevents certain kinds from hybridizing; but I have no doubt that this disparity will be overcome by first breaking the habit of these by more mutual crosses.

Mr. William Saunders, of London, Ontario, has, with much skill and labour, produced this season the following results in hybridizing, and has kindly permitted me to lay them before you.

FEMALE OR BEARING VINE.

Clinton—with Syrian pollen		Set	18	Berries.
"	" Muscat Hamburgh, 2 bunches	"	0	"
"	" 1 failed, the other set.	"	1	"
"	" Buckland Sweetwater	"	30	"
"	" Muscat D'Avni	"	8	"
"	" Black Hamburgh	"	5	"
"	" Grizzly Forulgnan—failed	"	0	"
"	" Black do do	"	0	"
"	" Chasselas Musque	"	5	"
"	" Royal Muscadine	"	22	"
"	" Victoria Hamburgh	"	18	"
"	" Rose Chasselas	"	13	"
	Total		121	

OF GOOSEBERRIES

Houghton's Seedling with	Warrington pollen	Set	8	Berries.
"	Roaring Lion	"	2	"
"	White Smith	"	1	"
"	Brown Girl	"	5	"
"	Ashton's Seedling	"	2	"
"	Crown Bob—failed.			
	Total		16	

Eight or ten flowers were operated on in each case, excepting Crown Bob, which was used on five only. He also operated on six or seven flowers of the Philadelphia Raspberry, with the Brinckles Orange; such were his results. Mine were as follows: I was unable to fertilize the Delaware with either the Black or Muscat Hamburghs, while one took readily with the Diana.

MALES.	FEMALES.	CLUSTERS	SET	BERRIES.
Black Hamburgh	Delaware	2	11	0
Muscat do.	Do.	1	"	0
Chasselas do Fontainebleau	Do.	1	"	0
Rose Chasselas	Do.	1	"	1
Do.	Diana	1	"	13

Do. Do.	Isabella	1	"	0
Muscat Hamburgh	Diana	1	"	26
Bowood Muscat	Rogers' No. 4	1	"	27
Delaware	Do. Do.	1	"	17
	Total			114
Mr. Saunders' total				121—235

So slow and tedious is the process, it will be observed that only a limited amount of labour can be performed by one person during the time of flowering. Mr. Saunders exceeds me by seven berries. Now to test the quality of only a portion of these which may survive the vicissitudes of germination and other mishaps, it will take from six to eight years. I know no reason why the Government should not protect, by patent, the production of new fruits; they are in point of fact quite as worthy as any other production of science and skill.

Yours respectfully,

WM. H. MILLS.

Hamilton, 24th August 1868.

Garden Seeds.

FARMERS are sometimes apt to be dependent on the salesman for their yearly supply of garden seed; whereas a little forethought and attention at the proper season, would not only save them annually the sums expended in purchasing seed from the store, but would ensure the required article of the proper age and quality, and would also give better opportunity of making improvements in the different varieties. To do this, however, care and judgment are necessary. It will not answer to adopt the principle of selling aside the last-ripe, or the smallest products of either garden or field, for the next year's sowing. Potatoes too small for use are unfit for planting, and late ripened seeds of any kind will probably yield a late maturing plant the next season. Let the farmer make his selection from known varieties, the qualities of which he has tested. Let him set aside early in the season a single plant or two of promising appearance, for the special object of growing to seed, and bestow on these plants special attention. He will thus secure germs that will probably yield more luxuriant growth and better quality in the succeeding product. He will certainly save himself the disappointment of obtaining old seeds instead of new, or a different variety from that which he expected. Having secured his seed, he must of course be careful to place it in security from damp or the depredations of mice, and must not omit to label each parcel with the correct name, and the date of the contents. These are simple matters, scarce calling for notice, yet in how many instances does failure come from inattention to them. We know not a few who make a point of saving seed in the fall, and yet have invariably to purchase their supply in spring. Mice, or damp, or want of care in labelling, or some other equally trifling cause, have defeated all their pains.

Gathering Fruit.

THE appearance and the value of fruit depend very much upon when and how it is gathered. Strawberries, if picked carefully, with half or quarter of an inch of stem attached to each berry, and laid carefully in the basket, will carry better, and sell for a greater price, than when pulled hap-hazard, some with hulls and stems on, and some with them off. Again, if they are gathered when they are perfectly dry, they will keep longer and retain a better flavour than if gathered while wet. A little water not only hastens decay, but it rapidly destroys the flavour of many delicate soft varieties. After being gathered, they should never be allowed to stand out exposed to the sun, as with many varieties, it takes but a little while of exposure to a hot, clear sun, to destroy their brightness of color.

Peaches should be left on the tree until they are fully ripe, and then gathered carefully with thumb and finger, and at once laid in the basket or box in which they are to be marketed. If the bloom is rubbed off the peach by rough handling, its beauty of appearance is injured, and it will decay much sooner than if untouched. Formerly it was supposed that the peach must be gathered before being fully ripe, in order to ship it any distance, but practical experience has proved that ripe fruit, not quite soft, will carry quite as well as unripe, and command a much better price.

Pears and apples should never be picked from the tree by breaking the stems. Unless the stem will separate freely from the tree, the fruit is not ripe; it will neither eat nor cook good, and is only fit for those who want a touch of the cholera morbus. Apples, as gathered, may be sent directly to market, but nearly every variety of pear is improved in appearance and quality by keeping in close dark drawers, wrapped in flannel or soft paper, or packed in bran for a few days.

For profit, and in order to obtain the highest price, all fruit pays to be assorted into two or more grades. A few scattering large berries, apples, or pears in a quart or bushel, do not assist in advancing the price; but if carefully packed by themselves will bring the highest price, and often induce the dealer to buy the small fruit in order to get the large.—*Horticulturist.*

The Vineyards of the Islands of Lake Erie.

THE Kelley's Island correspondent of the Ann Arbor *Courier* says:—"The whole secret of grape culture here is all explained in the peculiar mildness of the climate. The large body of water surrounding the islands becomes so heated during the summer that the frosts do not come until December, not even severe enough to injure the tomato vines. The cost of raising grapes is moderate; one man can easily cultivate five acres—one horse, a plough cultivator, and a hoe is all that is needed. The grape roots are placed in rows, six by eight feet apart, and the vines are held by three rows of wires, strung on posts. In the spring, all the wood of last year's bearing is cut away, and from two to three vines of last year's growth are allowed to grow, being cut back from three to four feet from the ground. To secure a good crop, the vineyard must be well ploughed, cultivated and hoed, keeping it free from all weeds and grass. The price of grape land is $300 per acre, and when a vineyard is in full bearing, after a three years' growth, it is worth $1,000 an acre. The average net profit from one acre of grapes is $300, but as high as eight tons to the acre has been raised—which, at the low figure eight cents a pound, brings the snug little sum of $1,280. I have visited the vineyards on Middle Bass Island, and I find a great difference in the cultivation of the grape, some neglecting and others taking the utmost pains to keep them clean, in order to secure a good crop. W. W. Wicker and Capt. Atwood have the best prospect of a good crop of any I have seen—although not much over one-half a crop is expected, owing to the rot and mildew. The Concord, Delaware, and Catawba, are the best grapes raised here. One thousand acres of grapes are now in training, mostly on North Bass, Middle Bass, or Put-in-Bay and Kelley's Island, which together contain about 6,000 acres. Immense quantities of pure native wines are also made on these islands; the amount last year was 100,000 gallons. The Catawba wine is of an excellent quality. At the Paris Exposition, where all the noted wines of Europe were on exhibition, the American wine took the premium. It is a singular fact in this wine-making, that the wine always undergoes two fermentations; one when pressed from the grape, and the other the next spring, when the leaf and blossom of the vine appear. Large wine-cellars, capable of holding from 8,000 to 80,000 gallons, are built in the solid rock, arched over with stone or brick, in which the wine is stored until fit for market."

Eververgreens in August

THE latter end of August is one of the best seasons of the year to transplant evergreens. The young growth of the past season has got pretty well hardened, so as to permit of but very little evaporation—and the earth being warm, new roots push with great rapidity, and the tree becomes established in the ground before cold autumn winds begin. The chief difficulty is, that the soil is usually very dry, which prevents much speed with the operation; and the weather being usually very warm, the trees have to be set again in the ground almost as fast as they are taken up; so that it is not safe to bring them from a distance. It is as well, therefore, to make all ready in anticipation of a rain, when no time may be lost in having the work pushed through. Should a spell of dry weather ensue—which in September and October is very likely—one good watering should be given, sufficient to soak wet through the soil and about the roots. A basin should be made to keep the water from running away from the spot, and to assist its soaking in. After being well watered, the loose soil should be drawn in lightly over the watered soil, which will then aid in preventing the water from drying out soon again.

Towards the end of the month, and in September, evergreen hedges should receive their last pruning till the next summer. Last spring, and in the summer, when a strong growth required it, the hedge has been severley pruned towards the apex of the cone-like form in which it has been trained, and the base has been suffered to grow any way it pleases. Now that, in turn, has come under the shears, so far as to get it into regular shape and form. It will not be forgotten that, to be very successful with evergreen hedges, they ought to have a growth at the base of at least four feet in diameter.—*Gardener's Monthly.*

☞ A farmer in Oneida, N.Y., raised seven thousand quarts of strawberries on a single acre this year.

The Apiary.

Cause of Bees Robbing.

THE principal cause of bees robbing is want of forage. Bees will seldom, if ever, rob when they can find plenty of flowers to work upon; but when flowers cannot be found, and the weather permits them to fly, their great anxiety to labor causes them to seek for honey even in the neighbouring hives. Hence, in the spring and fall, or before the honey season commences, and after it closes, bees are much inclined to rob each other, and sometimes, for want of a little attention, cause the apiarian much trouble and loss. It frequently happens that a stock of bees, becoming overpowered by robbers, join in with them and assist in carrying away all their stores, and the bee-keeper very unexpectedly finds his hive minus bees and honey.

As a rule, however; stocks that are attacked by robbers are defective in some way; that is, if a stock is being robbed in "right good earnest" we may conclude that it is queenless or has a drone-laying queen, or from some other cause is very weak. Robbers may, and not unfrequently do, attack strong stocks; in such instances they are generally handled rather roughly, and soon leave.

Every bee-keeper will have noticed in the fall, after the honey harvest is over, on the lighting boards of his hives, or some of them, a single bee surrounded by others. The bee surrounded is a strange bee, or robber; they hold it a prisoner; some are biting its legs, some its wings, while another is ready to take what honey it has—for by the continual biting of the bees it is forced to give it up. If the stock is queenless, or otherwise weak, these robbers increase until they will come and go in a perfect swarm, and sometimes in a few hours carry away all the honey in a hive.

To prevent robbing, the entrances to all hives should be contracted, as soon as the honey harvest ceases, to a very small opening, especially if stocks are weak. When it is discovered that a stock is being robbed, and contracting the entrance does not stop the robbing, it must be removed to a dark cellar or out-house for a day or two,—then bring it out and examine it, and ascertain the cause, and apply the remedy. If queenless, or possessing only a drone-laying queen, give them another, or join them to another stock that has a queen. If not queenless, but very weak in bees, exchange places with some strong stock. If it is discovered that one stock in the apiary is robbing another, put the stock of the one that is being robbed in the place of the one that is robbing; in other words, exchange places with the two socks, and the robbing will generally cease. This should not be done, however, unless it is clear that the robbers are getting the advantage. But the best preventive of all is to keep strong stocks, and be sure they are not queenless.

Swarming Extraordinary. — Queenless Stocks.

To the Editor of THE CANADA FARMER:

SIR,—On the fourth day of this month, I took an artificial swarm from one of my hives of bees, and cut out all queen cells but one: On the twenty-third that same hive cast a natural swarm, and on examination I found that same queen cell open at the lower end, but no other in the hive in any stage, and no eggs. I returned the swarm to the hive, and they are doing well.

On the twenty-third of this month, one of my hives swarmed, and the bees returned to the hive without clustering. I examined and cut out all queen cells but two. Soon after I found a queen on the ground, with one wing gone and a part of the other. I placed her on the alighting board, but the bees attacked and killed her. She might have come from another hive, which swarmed and returned the same day. Yesterday, this hive from which I had cut the queen cells on the twenty-third swarmed again, and the swarm clustered in two separate clusters, some distance apart. On examining the hive, I found the two queen cells open at the lower end, and no other in the hive, nor any young brood or eggs. I returned both clusters to the hive, and this morning found one, and only one, queen thrown out. Both stocks were in the "Thomas" hive.

I would like Mr. Thomas or anyone else to explain these phenomena. It seems to me that we have here a way of accounting for queenlessness which I have not seen mentioned by any writer on the subject.

THOS. C. HILL.

NOTE BY ED. C. F.—A swarm issuing under the circumstances as related in the first instance is not a common occurence; yet sometimes it is the case, and may be accounted for in this way. The excitement caused by the queen leaving the hive on her bridal tour, causes the bees to rush out after her, and cluster as in other cases.

The second instance related is a more common occurence. It not unfrequently happens that all the queens in the hive hatch about the same time, say during a night; the result is, the next day, when the bees swarm, all the queens leave the hive, and there being no eggs, the stock is queenless and unable to raise another.

Swarms issuing under similar circumstances have been known to contain four and five queens. Sometimes the bees will all cluster together, and sometimes separately, as in the instance related by Mr Hill. When returned to the hive, all the queens will be destroyed, except one, as in this case. The queen found, probably issued from the stock out of which Mr. Hill cut the queen cells, or it may have issued from some other, as suggested by Mr. Hill.

More stocks become queenless from all the queens swarming out than is generally supposed.

☞ An Ohio exchange says something is the matter with the bees this summer. They refuse to send out swarms, or make any honey.

BEES EARLY SWARMING.—Most of our writers on the honey bee say look out for swarms from nine a. m. until four p. m., and being an amateur in bee-keeping, I was surprised on Sunday morning, July 5th, at *a quarter past six, a.m.*, to see a fine swarm issue from one of my hives, and another swarm from another hive at *half-past seven*. I think it would be advisable for your bee-keeping readers to keep a look-out next season a little earlier than usual in the morning, and perhaps save some swarms of bees by so doing.

WM. M. H

Township of Kingston, Aug. 6, 1868.

TREATING BEES WITH COLD WATER.—Bees in swarming have been known to alight upon persons and animals, stinging them severely, and in some instances causing death. The *American Bee Journal*, in referring to an instance of the kind, where a swarm of bees recently settled upon the head of a horse standing in front of a church, and the owner, who went to its assistance, was stung senseless, says that all the difficulty could have been obviated by the use of cold water.

In such cases the *Journal* advises a prompt application of a few gallons of cold water sprinkled from a common watering pot directly on the clustering bees. It remarks that "a little knowlege, presence of mind and calmness would have been serviceable here; for nothing is more apt to rouse the ill temper of bees than to come in contact with a sweaty horse; and a horse is a most helpless animal when attacked by bees."

During the extreme hot weather of July we had several swarms come off that were extremely irritable, and we treated them to a sprinkling of cold water, after which they became quiet, were easily handled, and were hived without the least trouble.

The Household.

Citron Preserve

SOME of our readers, obseves *The Farmer* (Scottish) may have felt a little puzzled, at hearing friends from Canada or the northern United States descant on the excellence of the citron preserves which they were in the practice of making when at home, and that, they will affirm, from veritable citrons grown by them in their own gardens there, and out of doors too. What! Citrons grown in the open air, where the winters are even much colder than in Britain! As well grow oranges also, for wherever citron trees will grow, orange trees will grow equally well, and often better. But citrons do not grow on trees, the transatlantic friend will reply, for they grow upon vines, like those of cucumbers or vegetable marrows. Here, then, there must be some mistake; and that there certainly is, which, however, is cleared up by a little further explanation, when it appears the fruit of the so-called citron is not the fruit of the true citron, *Citrus Medica*, from which the preserved citron peel of the shops is made, but that of the citron gourd, or citron water-melon, a variety of *Curcurbita Citrullus*, for the cultivation of which, and the preserving of its fruit, the following directions are given in Messrs. E. G. Henderson & Son's Seed List for the present season :—

"This is a truly valuable, and highly-interesting esculent fruit, and constitutes a true variety of the hard-fleshed water melon, which, though not edible in its raw state, is now approved and strongly recommended for its valuable adaptation in making a very delicious preserve. It requires the same treatment by seed as the common ridge cucumber. The following directions are given as a successful method of preparing the preserve :—Pare the fruit, and let out the seeds, taking out the soft pulp for after use, and weigh the remainder, cutting it into convenient lengths and thicknesses. To every 1½ lb. of the firm fruit, apportion a lemon and 1 lb. of the finest double refined loaf sugar, with 1½ pints of spring water; then pare the lemons thin into a basin, and squeeze the juice to the rind, and let it stand to get out the flavor. Put the fruit and most of the water into the preserving pan, and stir it till it is soft and transparent; which will be from three to four or even five hours, adding the remainder of the water, if needed, from time to time, until the opacity of the preserve gives place to transparency in the flesh. When boiled soft, add the sugar and skim it; and when the syrup is well formed, strain the lemon juice to it, and by the time this is well incorporated, the preserve will be done. It ought to be of a transparent clearness, and of a fine apple-green colour, and citrontaste. If duly prepared, it forms a most valuable addition and equivalent as a sweetmeat, and a delightful change from the rich aroma of the raspberry, or the pleasant acidity of the marmalade; and if boiled somewhat longer than the directions given, it assumes a guava-like flavor which tastes excellent; the soft pulp will also form a good preserve with the same preparation as above. If used before the fruit becomes over-ripe the pulp is tolerably solid."

On submitting the above recipe to a lady who had frequently made citron preserve in Canada, we were informed that it was somewhat different from the mode she had practised, which was as follows, the fruit being used before becoming over-ripe, or prior to the inner portion becoming pulpy or soft :—Quarter the fruit, then pare and cut in slices, each rather more than one inch in thickness, pick out the seeds, cut in pieces about one inch square; boil slowly for several hours in water, till the pieces are quite transparent, strain and throw away the water, make a syrup in the usual way, using 1 lb. of crushed lump sugar to 1 lb. of fruit, adding half a lemon, sliced, with the rind on, and a quarter of an ounce of ginger for every 1 lb. of sugar. Put the pieces into the syrup, and boil for twenty minutes, then dish in small jelly pots, as it is apt to candy if long open.

CLARK'S EXCELSIOR WASHING COMPOSITION.—In our last issue we noticed this newly patented article. We spoke of it then only on the testimony of others who had used and found it efficient and economical. We have since procured the requisite instructions from Mr. Clark, and had a trial made at home. We are now authorised to say that the experiment was perfectly satisfactory; that the scrubbing board was dispensed with, a slight amount of hand-rubbing being all the labor of the kind required; that the clothes were thoroughly cleansed, leaving them, when dry, of an excellent colour; and that much time as well as labor was saved in the operation. Less soap also was required than in the usual method; so that, in addition to the foregoing advantages, a saving is effected in expense. Domestics are not usually over ready to adopt any "new-fangled notions" and modes of proceeding in their own special department; but this invention has given such satisfaction, that in our family Mr. Clark's patent will in future be used, and we have much pleasure in adding our favourable testimony to the many commendations which his improved process has already received.

TO REMOVE THE SKIN FROM PEACHES.—Every one knows that there is a great loss of pulp in pearing peaches with a knife; to obviate which an exchange suggests the following method of treating them: Make lye as strong as possible of wood ashes and soft water. Fill a kettle with the lye, and when boiling rapidly, drop in twelve or eighteen peaches and take out again almost immediately, and immerse them in a pail of cold water. Take one in your hand, and you perceive that the rind will slip off entirely, leaving a round beautiful yellow ball; threw it immediately into another pail of pure water, and so proceed till all are done. This process will not injure the flavour of the finest peach, and once tried, the old-fashioned way of peeling with a knife will not be again adopted. If the lye is not strong enough, put into the kettle two dipperfuls of clean wood ashes. This is an excellent way to rid small onions of their jackets preparatory to pickling them.

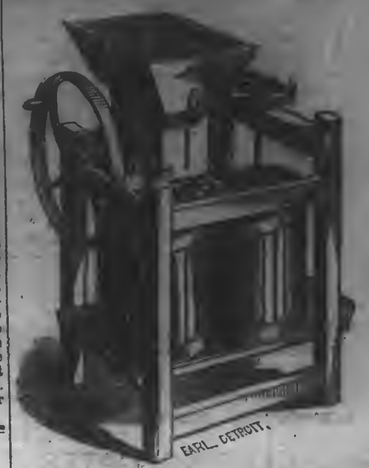
NEW PATENT CIDER MILL.



H. Sells' Patent of 1866.

THIS MILL first CUTS and then CRUSHES the apples perfectly fine, making a saving of more than one-eighth of the cider over any other Mill. It NEVER CHOKES, owing to its novel discharge, and is very substantial. It carried off the first prize at the Provincial Fair held at Kingston, 1867, and also was awarded a diploma the same Fall at the N. Y. State Fair, held at Buffalo. Hundreds of these mill's are now in use in Canada and the United States, giving the best of satisfaction. We furnish this Mill and Press complete, with two Curbs, for $30, or Double Mill on the same principle for $35, (at our factory). Both are equally adapted to hand or other power.

Farmers, send in your orders early, stating your Port or Station, and Post Office address. All orders will receive prompt attention.

Address

F. W. GLEN,
EXECUTOR, OSHAWA, ONT.

August 28, 1868. (5-17-tf.)

LEWIS' INCLINE
OR
SELF-CLOSING GATES.

THESE GATES are cheap and easy of construction, and are not liable to get out of order. Being self-closing, they are especially adapted for dangerous places, stock pastures, or wherever it is necessary to keep gates closed.

☞ For particulars and Rights apply to

RICHARD LEWIS,
MELBOURNE,
v5-17-1t* Provincial of Quebec.

FRUIT AND ORNAMENTAL TREES
FOR FALL OF 1868.

WE have the pleasure of announcing that we are prepared for the Fall Trade with an unusually large and well grown stock, embracing

Standard and Dwarf Fruit Trees.

Grape Vines, new and old sorts, strong open ground plants.
Currants, Raspberries, Blackberries, and all the small fruits.

ORNAMENTAL TREES AND SHRUBS,

Roses and Flowering Plants of every description.

Nurserymen, Dealers, and others, purchasing largely, will be dealt with liberally, and all orders, however small, will receive prompt and careful attention. Parties interested will do well to consult the following Catalogues, which are just issued, and will be sent pre-paid on the receipt of 10 cents. each, for Nos. 1 and 2, and 5c. for No. 3.

☞ No. 1, Descriptive and Illustrated Catalogue of Fruits. No. 2, Descriptive and Illustrated Catalogue of Ornamental Trees, &c. No. 3, Descriptive Green House Plants. No. 4, Wholesale Catalogue, FREE.

ELWANGER & BARRY,
v5-16-4t. MOUNT HOPE NURSERIES, ROCHESTER, N. Y.

THE BEST SHEEP MARK YET INVENTED.

It is made of tinned wire stamped with name and number. Is cheap, does not wear out, and looks well. Price three cents each.

ARCHIBALD YOUNG, Jr.,
Sarnia, Ont.

☞ N. B.—AGENTS WANTED. v5-13-tf-c,o.l.

STERLING ALGUIRE'S
MILK AGITATOR,
PATENTED APRIL 16, 1868.

STERLING ALGUIRE PATENTEE,
FARMERSVILLE, ONT.

☞ For particulars address

J. B. HARRIS, ASSIGNEE,
Belleville, Ont.

The attention of dairymen is respectfully called to the following testimony from one of the best factories in Oxford County:

NORWICH, ONT., Aug. 28, 1868.

J. B. HARRIS,

DEAR SIR,—Your Agitator needs no recommendation, it will recommend itself, and every cheese manufacturer can become convinced by giving it a fair trial; for my part I would not have it taken out of my two vats for twice the price. No cream can possibly rise, and it cools the milk to the same temperature as the water with one-quarter inch stream of water.

v5-17-1t* Respectfully yours, H S LOSEE.

Markets.

Toronto Markets.

"CANADA FARMER" Office, Aug. 28th, 1868.

THE flour and wheat markets during the past fortnight have been very dull. There has been little or nothing doing in produce of any kind except in Barley; that grain has been offering freely. The season has fairly begun, and large quantities have already changed hands.

FLOUR AND MEAL.

Flour—The market has been very dull; holders are asking $6.50 for No. 1 super., but can find no buyers at that price; there is little or no demand; extra has been in fair demand for small lots at from $7.25 to $7.50; superior is altogether nominal, there being no lots in the market.

Oatmeal—In good demand for small lots at from $7.50 to $8.75.

Cornmeal—Small trade doing at $5.

GRAIN.

Wheat—New wheat has not yet begun to come into market. There is very little old wheat offering. Spring wheat and midge-proof are nominally worth $1.35 to $1.40, and Fall $1.45; on the street market a few loads sold as follows:—Spring wheat $1.35; midge-proof $1.32 to $1.35.

Oats—The market is dull; holders are asking 50c. for car lots; on the street market 50c. to 62c. has been paid for a few loads lately.

Barley.—The past week has been an active one with Barley buyers; as much as 60,000 bushels has already been shipped from this port to Oswego since the season commenced; the daily receipts by teams are considerable, amounting to from 10,000 to 15,000 bushels per day, the receipts by cars have averaged 3,000 to 5,000 bushels per day during last week. Prices remain steady at from $1.05 to $1.06. There are only two or three buyers in the market, the majority of operators being afraid to "go in" at present prices. Every bushel offering is, however, eagerly bought up at the rates named. It is generally thought that prices are higher than the state of foreign markets warrant, and a decline is therefore looked for by not a few. We think it not unlikely that rather lower prices will soon rule, and advise Farmers to take advantage of the present rates and at once bring their crop into market.

Peas.—There has been nothing doing during the past week. Prices are altogether nominal. On the street market there is none offering. Loads from farmers would bring 95c.

PROVISIONS.

Pork.—There is no change in the market. The few lots in holders' hands are held firm at quotations, and the demand is good.

Bacon.—Trade very limited. We quote 11c. to 12c. for Cumberland and Canadian.

Butter.—The market has ruled firm at our figures for the past week. Shippers refuse to advance, as prices are supposed to be dangerously high. We quote really fine for city use, 20c. to 21c.; ordinary round lots taken by shippers, at 17c. to 19c.; rolls on the market, 23c. to 26c.

Eggs.—Freely supplied at 10c. to 11c. for fresh.

Cheese.—Scarce and wanted, at 11c. in lots.

THE CATTLE MARKET.

Beeves.—The market has been well supplied during the week. Some five or six car loads were purchased for the Montreal market. First-class cattle are still scarce and in demand; second and third-class cattle are in good supply.—We quote per 100 lbs. dressed weight:—1st class $6 50; 2nd, do. $5 50; 3rd, do. $4 50.

Sheep and Lambs.—The market has been well supplied. There have been large arrivals by rail, principally from Seaforth. We quote:—*Lambs*, 1st class, $3 each; 2nd, do. $2 to $2 25 each; 3rd do. $1 to $1 25, each. *Sheep*—1st class $4 to $4 50 each; 2nd, do. $3 to $3 50 each: 3rd do. $2 to $2 25 each.

Calves.—Veal being out of season very few are coming in; selling at from $4 to $6 each.

Hides and Skins—Hides, green, rough per lb., 5½c. to 6c.; do. green, inspected, 7½c.; do. cured and inspected, 7½c. to 8½c.; Calfskins, green, 10c; do. cured, 12c., do. dry, 18c. to 20c.; Lambskins, green, 50c.; Pelts 40c.

HAY AND STRAW.

Hay—There has been a large quantity offering, and the demand is brisk. Prices have ranged from $12 to $15 per ton.

Straw—Not much coming in. Selling at from $8 to $14.

London Markets, Aug. 25.—The attendance and amount of business transacted on the Market Square to-day was perfectly satisfactory. The grain receipts were large, quickly taken up at fair prices, and wheat, both fall and spring, remained steady throughout. Barley and peas were in good demand; competition for peas, however, towards the close, was less keen, barley keeping unusually stiff. Other seasonable products were well represented and met a fair demand. Butter is much inquired after, and from recent appearances will rule high this winter. For other articles see quotations; red fall wheat, per bushel, $1 25 to $1 27; old spring wheat, $1 25 to $1 30; new spring, do. $1 20 to $1 25; barley, 92c. to 96c.; peas, 83c. to 86c.; oats, 35c. to 37c.; corn, 80c. to 85c.; buckwheat 64c. to 70c.

Galt Markets.—Our market is unusually crowded to-day. Fall wheat quoted at $1.25 to $1.30; seed fall wheat $1.30 to $1.55; spring wheat, $1.20 to $1 25; potatoes $1.40 to $1.50; tomatoes $1.50 to $2.00; butter 17c. to 19c.; eggs 10c. to 12½c.

Hamilton Markets, Aug. 25.—White wheat per bushel $1.25; do. red winter, $1 23; do. spring $1,25; barley, 95c. to $1; peas 90c. to 95c; oats, 43c.

Milwaukee Markets.—Aug. 26, noon.—Wm. Young & Co.'s report.—Wheat—Receipts, 44,000 bushels; shipments, 7,000; No. 1 wheat, firm at $1 75; No. 2 wheat, at $1 64. Flour quiet and unchanged. Pork firm. Freights at 15c.

Chicago Markets, Aug. 26, noon.—William Young & Co.'s report.—Wheat—Receipts, 106,000 bushels; shipments, 26,000 bushels. No. 2 wheat active at $1 66. Corn at $1 01½; receipts 152,000 bushels; shipments, 182,000 bushels. Pork firm and unchanged.

THE CANADA FARMER is printed and published on the 1st and 15th of every month, by the GLOBE PRINTING COMPANY, at their Printing House, 26 and 28 King Street East, Toronto, Ontario, where all communications for the paper must be addressed.

☞ Subscription Price $1 per annum, (POSTAGE FREE,) payable in advance. Bound volumes for 1864, 1865, 1866 and 1867, can be had for $1 30 each. Subscribers may either begin with No. 1 of the present Volume, or with the first No. of any preceding volume. No subscriptions received for less than a year, and all commence with the first number for the respective years.

CLUBS will be furnished at the following rates:—
TEN COPIES for ..... NINE DOLLARS.
TWENTY COPIES for ..... SIXTEEN DOLLARS.
FORTY COPIES for ..... THIRTY DOLLARS.
ONE HUNDRED COPIES for ..... SEVENTY DOLLARS.

To Agricultural Societies ordering more than 125 copies, THE FARMER will be sent at SIXTY CENTS.

THE CANADA FARMER presents a first-class medium for agricultural advertisements. Terms of advertising, 20 cents per line space. Twelve lines' space equals one inch. No advertisement taken for less than ten lines' space.

Communications on Agricultural subjects are invited, addressed to "*The Editor of the Canada Farmer*," and all orders for the paper are to be sent to

GEORGE BROWN,
Managing Director.

VOL. V. No. 18. TORONTO, CANADA, SEPTEMBER 15, 1868. POSTAGE FREE.

The Field.

Pure Seed.

THE importance of using only the choicest seed, the best of its kind and free from admixture, is universally acknowledged, though unfortunately not always so carefully carried into practice as it should be, and a stricter attention to a matter of so much consequence should be urged upon farmers gene-

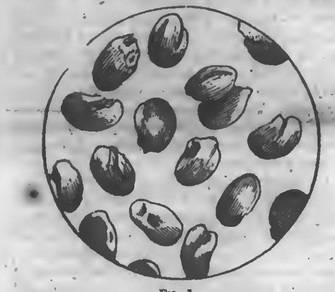

FIG. 1.

rally. Few persons now would employ small tubers to secure the best return from a potato crop. Yet the analogy between these tubers and ordinary seed is not exact; for it is in the eyes or buds that we should look for a closer resemblance, and here it must be acknowledged that the most vigorous buds will produce the most promising and thriving plants. Accordingly, it is that end of the tuber in which the

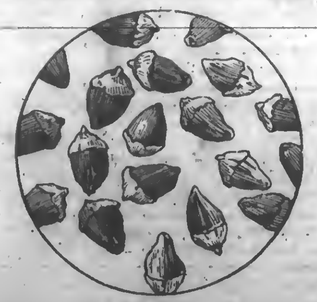

FIG. 2.

larger and more fully developed buds are congregated that all judicious planters use, and in dividing the root, take care so to perform the operation as to secure one or more of these buds in each set. This necessary care in the selection of seed is more easily and more frequently attended to in the case of the larger cereals. In planting Indian corn, the practical farmer early makes choice of the largest and finest ears, if he does not even set apart a piece of ground for the express purpose of raising seed, and bestow on this particular care in cultivation. Then, having secured the best ears, he even rejects from these all but the completely developed kernels, throwing aside those at the base and top of the cob. In wheat, again, the staple of Canadian agriculture, the greatest pains are taken to clean the grain and remove all small seeds of imperfect wheat or weeds, or foreign grain. But there is another class of seeds, in which, though the same care is called for, it is not quite so readily applied. In the case of the smaller seeds of turnips, clover, and the grasses, the minuteness of the grain renders their examination and the detection of imperfection or impurities not quite so easy. Yet the matter is not, after all, attended with any very great difficulty. In regard to turnips, it may be alleged that when so large a proportion of the plants that come up have to be destroyed in the process of singling, it is of no great consequence if a little adulteration is practised. Without admitting such a plea for careless husbandry, it may be granted that in fact there is less adulteration in the case of turnips than many other small seeds. It is the practice of seedsmen, and farmers would do well to follow the example, to test their seeds by counting out a definite number, say a hundred, and planting them; then noticing, after a sufficient interval, how many have sprouted. This will show at least the vitality of the seeds. But to detect adulteration in the case of the smaller seeds of grass and clover, some artificial aid to the sight is employed with advantage, and a good magnifying glass, or even a microscope, will be found of especial service.

In reference to this subject, an interesting article appeared recently in the *Farmer* (Scottish), from which we copy the following extract and the accompanying illustrations.

Premising that farmers are apt enough in judging of the minute differences in the appearance of the cereal grains, the writer of the article alluded to says:—"It may be safely concluded, that in order to acquire an equally discriminating acquaintance with the smaller seeds, they have only to accustom themselves to the use of the microscope, with which to magnify the smallest seeds to at least the sizes of wheat, oats, barley, beans, or others which they are accustomed to handle. Many look upon the use of the microscope as a mysterious and difficult operation, requiring far too much time, application and bother, for their having anything to do with it; but they have only to give it a fair trial in order to discover their mistake, disabuse themselves of all such absurd notions, and find, on the contrary, that it is in the highest degree interesting, instructive and useful, and even as an occasional treat to the young, its wonders will, in their estimation, vie with, if not surpass, those of the magic lantern, the kaleidoscope, and the wheel of life, while they will have a more potent influence in providing an after taste for intellectual and useful research. Many of the smaller seeds which, to the unaided eye, seem very much alike, yet present remarkably diversified, and often very beautiful appearances when viewed through a microscope of only ordinary power; and when one is accustomed so to look at them, the transition is easy to the investigation of the wide fields for micros-

FIG. 3.

copic observation which are embraced within the animal, vegetable, and mineral kingdoms.

Mixing, colouring, and killing, are all skilfully perpetrated in adulterating seeds; and all these arts, however artistically they may have been applied, are more or less capable of being detected by the microscope. Thus, with clovers and grass seeds, none are so exactly alike but that a difference can be

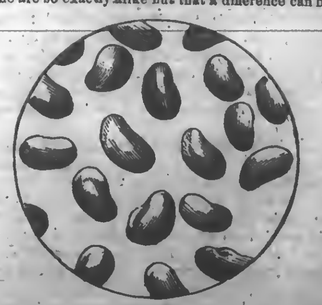

FIG. 4.

observed by a skilful microscopist, and most of the injurious or worthless kinds employed in mixing are so dissimilar that their detection is comparatively easy. This is not the case, however, with seeds of the varieties of turnips and other brassicæ, although

those of the different genera, such as common or rough-leaved turnip, Swedish turnip, rape, and even of some of their individual varieties, possess sufficient distinctive characteristics to enable a careful observer to find out whether or not they are mixed. The art of colouring has in the case of clover seed attained to great perfection; yet careful and repeated observation of the position and shading of the natural colours in the genuine seeds will serve to show the difference between them and the best examples of artificial colouring; which last is not nearly so applicable to grass and turnip seeds; but the sulphur smoking of the former, and the oil-dressing of the latter, serve to impart a freshness of appearance which the seeds do not actualy possess.

Killing is generally done by oven-heating (sub-roasting); or want of vitality may arise from extreme age in the seeds; in either case the seeds will appear dry when bruised, which is peculiarly marked in turnip, rape, and other oleaginous seeds, from the comparative dryness or absence of oil which they exhibit when crushed. Most people are familiar with the difference between fresh and roasted peas, and a similar difference in appearance is presented, under the microscope, between fresh and roasted small seeds.

For further illustrating some of the preceding results we are enabled, through the kindness of Mr. James Bryson, optician, Edinburgh, to give the four accompanying engravings from magnified photographs, prepared by him, the first three of which are from a sample of what, in market phrase, was termed "good red clover seed," and the fourth from another of good yellow clover, medick, or trefoil seed.

No. 1 shows really good plump seeds of red clover in different positions, when magnified by only a good pocket microscope. It is usually of a shaded purplish and yellowish colour, some of the seeds being entirely yellow; and at the Great Exhibition of 1862 there was a Norwegian sample similar in colour to No. 4; although the form of the seeds showed that they belonged to the true red clover—Trifolium pratense—some of our native wild varieties of which have also yellow seeds.

No. 2 represents imperfectly ripened seeds of red clover, enclosed in their still adhering husks. These as shown in the engraving, resemble small acorns with their cups attached; and in sample, they are so unlike the seeds of any of our field weeds that many have taken them for those of the dodder, the pest of Dutch clover fields. In the sample from whence they were taken these were present in about the proportion of six per cent.

No. 3 exhibits different views of the rib-grass, common ribwort, or plantain seed—Plantago lanceolata—magnified on the same scale as the others. This was present in the sample to about thirteen per cent.; and, being of comparatively little value, it is too generally introduced among clover seeds for the purpose of adding a "paying per-coniage" to the dealer's profits. It is, however, well known by its deep brown colour, somewhat shining appearance, and different shape to that of the clover seed, and being easily distinguished by the naked eye, those who purchase it from sample have themselves to blame.

No. 4. Yellow clover seed—Medicago lupulina—is of a uniform sulphury yellow colour, and more regular kidney-bean-like shape than the red clover seed, from which it also differs in possessing a distinct peculiarity of smell. None of this seed appeared in the sample from whence the preceding three were selected, although it is more employed than any other for adulterating red clover seed, both in its natural state, and when "improved" by colouring.

While fraudulent dealers have everything to lose, the fair dealer has nothing to fear, but much to gain from microscopic or other investigation; for how often do we see careless cultivators blame the seedsmen for sending them a mixture of weed seeds, when the fault of weed growth was entirely their own."

Agriculture.—Its Advantages.

To the Editor of THE CANADA FARMER:

SIR,—I propose to set down briefly some of the leading advantages and disadvantages of Agriculture, as a pursuit, and for the present shall consider the first of these topics. Agriculture is the art or science of cultivating the earth. Its object is to develop from the soil as large a quantity of vegetable products, and indirectly of animal products, as possible. *It conduces to health.* With what different feelings do the merchant and farmer leave their pillows in the morning; the one, cheerful with good health and buoyant spirits, goes forth to his labours at the dawn of day, greeted by the music of the feathered songsters, breathing the pure, fresh air, sweetly scented by the odour of the flowers; the other, perhaps after a sleepless night, walks in a thoughtful mood to his counting house, probably anticipating the insolvency of his customers, or the ill-success of a voyage. How many an invalid that has seen the ploughboy on his way to his work in the morning, whistling as he goes, has wished for a pastoral life. The evidence of statistics show that the agricultural population live to a greater age than any other. *Agriculture secures ordinary wealth.* No other occupation or profession can furnish from its own means the supplies for all our necessary wants. Food, raiment, and many luxuries, are among the fruits of the farmer's cares and labour. Although the farmer may not become so wealthy as some of our merchant princes, yet take the whole class of merchants with all the farmers, and the average wealth of the latter class, if it does not absolutely surpass, will compare favourably with the former. Not only does it secure individual, but also national wealth.

It promotes morality.—It tends to preserve the morals and raise the heart to Him who giveth seedtime and harvest. This was man's original occupation, and even now, the missionary tries, after proclaiming the gospel to the heathen, to induce them to cultivate the soil, as the best method of keeping them good Christians, and civilizing the remainder of the tribe.

It tends to independence.—With what honest pride the farmer can look over his golden fields, his richly laden orchards and growing flocks, with the happy assurance that his substance is increasing from year to year, and that he himself is far above want. The manufacturer or merchant often fails, although he may give his whole time and attention to his business, for the fault does not always lie in himself, but probably in some foreign market, or in the insolvency of some of his hitherto good customers. But what has the intelligent and industrious farmer to fear? His funds are invested in solid ground; he depends on no earthly guarantee, but on the All-wise Being, the giver of every good and perfect gift. Society is divided into the producers and non-producers. To the former class the farmer belongs, while the latter class have to depend upon the producers; hence we often hear the merchants and mechanics wishing for a good crop, and have nearly as much anxiety about the harvest as the farmer himself; they must depend to no small extent on the farmer for what they eat and wear.

The pursuit of Agriculture *gives scope for intellectual pursuits.* There is no business that demands such extensive knowlege. The farmer has to deal with the works of nature, learn the different characteristics of the earth, the air, and the seasons. He must know something of vegetable and animal physiology, entomology, etc. Besides, he must understand mercantile business. If in the future the farmers of Canada wish to be successful, they must pay more attention to agricultural education.

It is pleasant.—There is no other occupation or profession so useful, so honourable, so healthy, so happy, and so independent. Surely such an occupation must be gratifying. The pleasures of rural nature are consistent with every period of our lives. Why, then, it may be asked, has agriculture been so distasteful to farmers' sons? The hard manual labour which many of the farmers have had to enduro, and the little education which they possessed, may have hindered some from engaging in this pleasant occupation. But times are changing. Animal labour is being substituted for manual, and more recently, the natural and mechanical powers for animal labour. The use also of agricultural chemistry is coming more into vogue. These are sure indications of the progress of agriculture. The intellectual labour of the farmer is increasing, while the manual is decreasing. Science and art are rapidly multiplying his appliances and elevating his calling. "*Agriculture,*" says a recent writer, "*is an art,*—Man is the artist; the soil his laboratory; manure his raw material; animal strength and machinery his power; air, heat and moisture his agents; and grains, roots, fruits and forage his products."

CULTIVATEUR.

York Township.

How to Enlarge our Crops

To the Editor of THE CANADA FARMER:

SIR,—The following extract from a speech of Mr. Mechi, at Birmingham, deserves our thoughtful attention:—

"Keeping the crops free of weeds is, I know practically, one of the best and cheapest methods of enlarging our crops. The last saving a farmer should resort to is that of hand or horse-hoeing. The neglect in this matter is painfully obvious, and robs the country of millions annually. Don't tell me of sowing thick to smother the weeds. The cultivation is worth the money irrespective of weeds. I always horse-hoe my wheat, beans and peas, once or twice with Garrett's horse-hoe (at about one shilling sterling per acre), and hand-hoe twice or even three times, at a cost of about seven shillings and six pence or ten shillings per acre. Women afterwards hand-pick any weeds that have escaped the hoes. We know by the leaves of our flowers when there is anything wrong below: so it is with our field crops, and as I came here by rail, certain billious-looking crops indicated an uncomfortable state of their roots, owing to the want of drainage or food in the subsoil, or in consequence of weedy competition."

The above teaches an important practical lesson worthy of being learned and remembered by every farmer in Canada. We cannot of course employ hand-labour here as they can in the old country, but we may do more to secure clean cultivation than we generally do. The implement named by Mr. Mechi—"Garret's horse-hoe"—is perhaps known to you. Are you aware which of our cultivators or horse-hoes most nearly resemble it?

I have thought an implement is wanted specially to cultivate and keep clean the *borders of our fields* close up to the fences, as there the weeds are apt to accumulate. Perhaps some of our artisans connected with the manufacture of agricultural implements may devise some addition to the ordinary plough to fit it for such a purpose.

A FRIEND TO IMPROVEMENT.

Township of York, 31st Aug., 1868.

Refuse from Flax Mills.

To the Editor of THE CANADA FARMER:

SIR,—In your last number a subscriber asks:—"What is the best manner of utilizing the waste from flax mills for agricultural purposes; whether it should be rotted, and if so, what is the readiest and quickest mode of effecting this object?"

I take it for granted that by flax mills your correspondent means mills for scutching flax, and by the waste, what is commonly known as the *shives* of flax. If the mill is worked by steam, the best manner of utilizing this waste is to use it as fuel in generating steam; but if the mill is worked by water, then the waste should be used as manure. Now, it is a well known fact that the most substantial manures, if they are not well rotted, produce a less active effect on the growth of plants than the simplest fertilizers which have been reduced to a state of extreme division.

Then as to the readiest and quickest, and the least expensive mode of effecting this object, he should make a compost of the waste with horse-dung &c., turning it before it ferments too much, and if necessary, watering it with liquid manure.

A. K.

Toronto, 7th Sept. 1868.

Muck for Hops.

To the Editor of THE CANADA FARMER:

SIR,—I herewith send you a sample of stuff that I have commenced taking from a beaver meadow, for manure, composed of wild grass, sod muck, and a white composition which I suppose is marl. Will you please say, through the CANADA FARMER, what you think of the sample sent as a manure for hops planted on sandy loam; and how should it be proportioned and prepared?

JAMES MATTHEWS.

Acton, Sept. 5, 1868.

NOTE BY ED. C. F.—From the appearance of the specimen alluded to in the foregoing communication we should think the material admirably adapted for the purpose to which our correspondent is applying it; and, indeed, the soil which he describes, enriched with such manure, could hardly be surpassed for hop-growing. The white substance is shell marl, and furnishing carbonate of lime would be a valuable addition to the vegetable manure. We believe the best way to use it would be to compost it with barn-yard manure, turning the heap once or twice, and taking care to cover from the leaching effect of rains. The manure should be applied in the spring, liberally: of course it would not be lost if applied this fall. For fuller directions as to the method of applying it we refer our correspondent to the number of the CANADA FARMER for May 1, 1867. We trust his energy and industry will be amply rewarded.

ARTIFICIAL HARVESTING.—A process of artificially drying and curing hay and sheaves of grain in wet seasons has been brought before the notice of British agriculturists, by Mr. Gibbs, in a prize essay. The process, which Mr. Gibbs has subjected to the test of actual experiment, consists in passing the hay or sheaves to be dried through a shed supplied by a furnace and fanney with a continuous current of hot air. The method is endorsed by the approval of some of the best agriculturists in the kingdom.

Stock Department.

Animal Heat.

IT is common to speak of animals as either warm-blooded or cold-blooded, yet the true distinction is scarcely accurately indicated by the expression; for there are circumstances in which the so-called cold-blooded animal would be warmer than one of the other class. The difference between the two consists in the power which the first possesses of maintaining a uniform temperature under all ordinary external conditions, while the temperature of the other class of animals rises or falls with that of the atmosphere or medium in which they are placed. Among vertebrate animals, mammalia and birds constitute the warm-blooded order, and fishes and reptiles the cold-blooded. The temperature of the blood and internal parts of the body, in the first, ranges from 98° to 111°, being in the mammalia from 98° to 106°, and amongst birds from 107° to 111°. In man and the domestic animals, the ordinary temperature of the body is about 98°; and this temperature is maintained with wonderful uniformity under great extremes of external condition, varying very slightly through all the range of climate from the Arctic to the Torrid zone. With the aid of clothing, indeed, and the addition of suitable diet, man can maintain his normal temperature, and adapt himself to the condition of the external atmosphere through a range of over two hundred degrees, Fahrenheit. It is proposed in the present article to explain very briefly how this uniform temperature is secured.

The main source of animal heat is respiration. So large a share, indeed, does this function perform in maintaining the temperature of the living body, that we may confine our attention to it alone, and leave out of consideration, for the present, the nervous influence and other subordinate agencies in this important vital operation. In explaining the process of respiration in a former article, it was stated that the oxygen of the air was absorbed into the blood with each act of inspiration, was then conveyed by the circulation to every part of the body, and uniting with carbon, formed carbonic acid. The carbon employed to effect this combination is found partly in the blood itself, but is chiefly derived from the waste portions of the various tissues disintegrated and decomposed in the constant processes of change going on through life. We are all familiar with the phenomenon of the rapid production of heat by the chemical combination of these two elements, oxygen and carbon. Almost every instance of combustion exemplifies it. Carbon and hydrogen are the principal elements of nearly all combustible substances, and the act of combustion is the rapid union of these elements with oxygen, resulting in the formation of carbonic acid (oxygen and carbon) and water (oxygen and hydrogen). The degree of heat evolved in this combination is definite, and can be measured and calculated; and it matters not whether the combination takes place rapidly, producing combustion, or more gradually, as in oxidation, the amount of heat evolved in the union of given quanties of these elements is the same. Now the amount of carbon thrown off by an adult man, in the form of carbonic acid, in respiration, is, under ordinary circumstances, as much as eight ounces in the course of twenty-four hours. Were we to burn this quantity of carbon or charcoal, we should, in a very few moments, produce an intense amount of heat. Precisely the same amount of heat would be extricated within the body during the course of twenty-four hours by the slower chemical combination of the quantity of carbon specified with the oxygen of the air. We are not very far from exact, then, in stating that we maintain the temperature of the body by consuming a certain amount of fuel. How, it will next be asked, is this fuel supplied? We have said it is obtained from the blood and the waste of the tissues. In either case, the supply is obtained from the food we take. This then is the ultimate source of animal heat.

In illustration and evidence of the foregoing view, which is now generally admitted among physiologists, we may notice certain well-known facts, and deduce some important practical lessons. The relation of animal heat to respiration is seen in the constant correspondence of the temperature of the body with the quickness or amount of breathing. Thus, those animals that breathe quickest, taking in the largest amount of oxygen, and parting with the most carbonic acid in a given time, have the highest temperature. Birds, whose breathing is quicker, have a higher temperature than mammalia. Again, the temperature of any animal sinks, if its breathing is reduced in force or frequency. Thus, during sleep, when the respiration is slower than during the waking state, the warmth of the body sinks in proportion. Exercise, which quickens the breathing, raises the temperature of the body. In the state of complete hybernation, the breathing becomes remarkably slow and almost ceases, and we find the temperature of animals in this state sinking almost down to the freezing point.

There is another very important point in which this subject should be considered. The ultimate office of a large proportion of the food we take is to keep up the heat of the body, and we find a close correspondence between the amount and the kind of food we require and the temperature of the atmosphere at the time. In cold climates and seasons we consume far more food than in warmer regions or periods of the year. We relish and require, too, a much more oily and richer diet in cold weather than in hot. These facts, which are so obvious in our own case, should be borne in mind in our treatment of animals under our care; and especially should we remember that an animal exposed to cold will consume, for the mere object of keeping up its heat, without deriving a particle of nourishment, in the ordinary sense of the term, a much larger amount of food than one which is sheltered from the severity of the weather. Economy, therefore, to say nothing of humanity, requires that we should house all farm stock during the winter, or at least that we should afford them adequate shelter, and keep them as warm as is compatible with their natural habits and health.

When the temperature of the surrounding atmosphere rises above the proper standard of blood heat, the requisite balance is maintained chiefly by the perspiration of the skin. The moisture exuding in this way from the body reduces the temperature by the cooling influence of evaporation.

Veterinary Department.

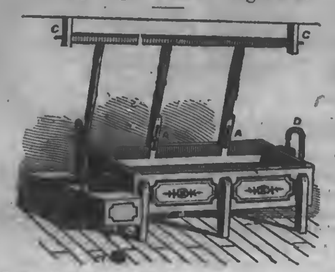
Injury and Disease of the Horse's Foot.

PUNCTURED FOOT, PRICKS, &c., form a very common class of injuries, and may result from various causes, as picking up a nail in travelling, or from pieces of glass or other sharp substance entering the sole or frog, and penetrating to the sensitive parts. The danger to be apprehended from these injuries greatly depends on the situation of the puncture and the direction it takes. If it be in close proximity to the joint, violent inflammation may be set up in that part, which is attended with very serious consequences; or the joint may be actually punctured, allowing the synovia to escape. This injury is attended with great constitutional disturbance, the horse being in a high fever. The symptoms vary according to the situation of the injury. The horse is observed to go suddenly lame, and the lameness to gradually increase. When the hind foot is the seat of the ailment, he moves with a long step and brings the foot cautiously to the ground; when standing, the fetlock joint will knuckle forward, and the heel is hot. Occasionally the lymphatics on the inside of the leg become inflamed, and the swelling will extend as far as the hock and groin. These are the symptoms presented when the offending agent has not been removed, or when suppuration has taken place as the result of the injury; therefore we cannot advise too strongly a careful examination of the foot in cases of sudden lameness where there is no visible injury. The shoe should be removed, and the sole carefully examined with the draw-knife, and any foreign body removed. The sole should be well pared in the vicinity of the wound, and if the puncture is deep, it is advisable to thin the sole all around. The foot may then be placed for half an hour in a bucket of warm water, and afterwards a poultice applied, either of linseed meal or bran; when heat and tenderness are removed, then the shoe may be applied, and it is generally safe to use a stopping of tar and tow.

Thrush or Frush is a disease often met with, and consists in a muco-purulent discharge from the cleft of the frog; the discharge is somewhat sticky and has a very fœtid odour, and is the result of a diseased condition of the sensitive frog, giving rise to an abnormal secretion which escapes from between the clefts of the frog. Thrush is oftenest found in the hind feet, and it may be produced by a variety of causes. It is occasionally a sequel to chronic diseases of the foot, as of navicular disease, and of laminitis, and is therefore frequently found occurring in the fore feet from that cause. In the hind feet it is usually produced from standing in damp, dirty stables, especially where the moisture is of an acrid nature, caused from the decomposition of the urine, &c. Horses in high condition, and more particularly such as are of a plethoric constitution, are very liable to thrush, as also to swelled legs, grease, &c. It is also most prevalent in the Spring and Fall months. In the treatment of this disease cleanliness is of the greatest benefit; indeed, without keeping the parts thoroughly cleansed, medical treatment is of little use. The affected parts should be well washed, and if the horn of the frog is detached and diseased the knife must be freely used, to cut away all detached and diseased parts, and also to allow the parts to be thoroughly dressed. An excellent application is the chloride of zinc, well diluted, which should be pressed in with a little tow and then covered up with tar. In mild cases a solution of sulphate of zinc, or sulphate of copper, has a very good effect. To prevent thrush, the feet, and particularly the cleft of the frog, should be kept clean, and an occasional dressing of tar is useful in preventing diseases, and at the same time tends to promote a healthy growth of horn.

The Dairy.

Sterling Alguire's Milk Agitator.



In cheese-making by the factory system the need of some contrivance to stir the night's milk was early felt, but the application of machinery to the purpose is a recent improvement. Milk agitators, as they are called, have now come into general use, being considered essential to a well-conducted cheese factory. The objects attained by gently stirring the milk are its gradual cooling, the removal of the animal odour, and the retention of the cream in the body of the fluid—all three very important points; and though it is true with regard to the last that the cream after it has risen may be stirred in again, still it is not so thoroughly incorporated with the milk as if it had never been separated.

The invention represented in the accompanying engraving has been found to answer the desired end most satisfactorily, and is now in extensive use, both amongst our own cheese factories and in those of the United States, where we have seen it in actual and satisfactory operation. It is manufactured by Mr. J. B. Harris, of Belleville.

The annexed illustration will sufficiently explain the principle of the contrivance, which is, indeed, very simple. The milk vat is double, the outer case being designed to contain water, which flows in at one end and out at the other, where it is received into a box divided into two compartments, and so constructed as to be capable of rocking to and fro. As the water flows into one of these compartments, it gradually tilts it over, when, of course, the water will flow into the other compartment, and as the first meanwhile empties itself through the aperture G, the second, becoming filled in its turn, will tilt the box over on the other side. This oscillating movement furnishes the power required to set the agitator in motion, as will be seen by a reference to the illustration.

Mr. Harris brought to this office a small model of the machine, which we had an opportunity of examining, and which clearly shewed the simplicity and efficiency of the arrangement. This gentleman also shewed us a number of testimonials from the proprietors of various cheese factories, all of whom spoke in the highest terms of the admirable working of this milk agitator. The most recent of these is from the Hon. David Reesor, of Markham. It is addressed to Mr. Harris, and is to the following effect:

"The agitator you put in my cheese factory gives entire satisfaction. Mr. Malone, who is in charge, informs me that it quite exceeds his most favorable expectations of the value of Alguire's Patent. I have no hesitation in recommending it as very indispensable in a well-conducted factory.

Yours truly,

D. REESOR."

We direct attention to Mr. Harris' advertisement in the present issue, and cordially commend this important invention to the attention of Canadian cheese manufacturers.

Rearing Calves.

The most important thing in the feeding of the calf is that it should receive the first milk from its mother. This milk, called *colostrum*, possesses purgative properties necessary to clear the intestines of the new-born calf. That clearance effected, the calf should be nourished for forty days with pure milk of good quality. This liquid constitutes complete nourishment, since it contains the assimilating elements necessary for the formation of the various parts of the young animal. In effect the pure milk contains:—caseine, to produce flesh; phosphate of lime, for the formation of bone; sugar of milk and butter, substances rich in carbon and hydrogen, to favor the assimilation and concur in forming fat.

If pure milk is not given in sufficient quantity—either from the cow not producing it (which is very unusual in natural suckling), or from the buttery matter being removed by skimming—the calf will not have the nourishment required for its organization. It will be less developed, remain small, and suffer during its whole life from the consequences of parsimonious and ill-directed feeding during the first period of its existence.

The calf is nearly always made to pass too suddenly from the diet of pure milk to that of skimmed milk, without adding to the milk despoiled of its buttery elements any substance capable of filling their place. To repair the loss which results from skimming the milk, we should add a decoction of flax seed; later, a decoction of beans, which contain caseine, mixed with an infusion of flax seed, which contains gum; add to this a small quantity of molasses, and we obtain a very nourishing drink.—*Gazette des Campagnes.*

New Cow-Milking Apparatus.

The *Mark Lane Express* concludes a very full notice of the Havre International Exhibition, by describing "a few odds and ends" found in the galleries. Among them we find the following account of a new cow-milking apparatus.

"As to a cow-milking apparatus, the invention of M. Liverbardon, Rue de Provence, Paris. We cannot say that we are an ardent believer in the milking of cows by mechanical means, certainly not in such as aim at effecting it by such means of a complicated character. The majority of farmers believe, and they have at least a great deal to say on their side of the question, that milking the cow, like some other operations in practical farming, is best done by hand, and that all complicated apparatus to operate this should be avoided. Certainly the apparatus now before us has not this charge of complication of parts to go against it. Nothing can indeed be more simple; it consists of a small silver tube, which is simply inserted in the orifice of the teat, and which serves as a tube by which the milk vessels completely empty themselves. The apparatus has been tried by several eminent Continental agriculturists, who speak highly of the completeness of its action and the ease with which it can be used; and whether the fact will have any weight with our readers or not, which will depend upon the views they hold of the prize system, the appliance has had a prize awarded to it at the agricultural show held at Amiens last year. Before inserting the tube, the teat should be filled or swollen out with milk brought down by hand; the tube is then inserted gently, giving it on its entrance a slight turning motion which will facilitate its passage into the orifice of the teat."

Bran for Milch Cows.

Plain bran or ship stuff, says the *Stock Journal*, is one of the very best kinds of food to increase the milk. It is not fattening. A steer could not be fattened on bran alone, and a cow, if fed on the best of hay and bran alone, might fall off in her yield, unless her strength and condition were kept up by Indian meal, or stronger food. If there were anything in which there would seem to be no strength, it is bran—the mere hull of wheat. It is not stimulating like brewer's grains, and can certainly do no harm, if it does no good; and yet any farmer who will make the experiment will find—or at least we have found—that a cow being otherwise kept in a proper condition, her yield of milk will be very considerably increased by giving her twice a day a feed of pure bran. The fact is patent, although we are not able to explain it. If there is any one article, which, while keeping up the health and strength of the cow, will also increase the supply of rich healthy milk, in our experience it is cotton seed cake meal. We have found this to have a great effect on the milk secreting organs. The cows at first do not seem to relish it, and it should be mixed with some other feed, but they soon come to like it, and we have never seen any bad effects in any way.

Meeting of the Fruit Growers' Association.

A meeting of the Directors of the Fruit Growers' Association, of Ontario, was held in the County Council Chamber, Prince's Square, Hamilton, on Monday, 7th Sept., 1868. Present, W. H. Mills, Esq., President, in the chair, His Honor Judge Logie, Rev. R. Burnet, Messrs. C. Arnold, A. M. Smith, L. Springer, W. Saunders, and D. W. Beadle.

The Secretary read the minutes of last meeting of the Board, and reported that he had communicated to the Secretary of the Board of Agriculture the resolutions affecting that body, and that he had received four essays on the cultivation of the apple, bearing the following mottoes, viz., "Vive et Disce," "Here's to thee, Old Apple-tree," "Fine Fruit is the Flower of Commodities," and "The Price of Good Fruit is Eternal Vigilance."

The Rev. R. Burnet and Warren Holton, Esq., were appointed judges upon the essays, with power to add to their number a third person if they found it to be requisite.

The Secretary presented the request of Mr. W. H. Read, of Port Dalhousie, asking for the appointment of a committee to examine his seedling grapes, eleven in number. The Directors appointed Messrs. W. H. Mills, Wm. Haskins, Chas. Arnold, A. M. Smith and D. W. Beadle such committee; and instructed them to examine them on the day after the meeting of the Fruit Growers' Association in St. Catharines.

The request of Mr. Chas. Arnold, of Paris, was presented, asking the appointment of a committee to examine his five new hybrid grapes. Messrs. D. W. Beadle, W. H. Reid, Wm. Haskine and Wm. Saunders were appointed a committee to visit Mr. Arnold's grounds an the 17th day of September, inst.

Messrs. J. Freed and A. M. Smith were appointed a committee to assist the Board of Agriculture, if required, in the arrangement and classification of fruits at the coming Provincial Exhibition.

His Honor Judge Logie, and Messrs. L. Springer, C. Arnold, J. A. Bruce and Geo. Leslie, were appointed a committee to examine the fruits that may be placed upon the table, both at the annual and October meeting, and report thereon before the close of the meeting—any two to be a quorum.

A letter was handed to the Secretary from J. R. Martin, Esq., stating that he had set out to attend the meeting of Directors, but had been obliged to return.

Mr. W. Saunders submitted to the meeting a new insect pest, which he had discovered feeding within the seed kernel of the Clinton grape, causing the berry to shrivel and drop prematurely. Mr. Saunders kindly consented to prepare a report embodying what was now known of this insect. A resolution was passed thanking Mr. Saunders for submitting this new pest to the inspection of the Board, and directing that Mr. Saunders' report be sent to the Canada Farmer for publication.

The subject of compensation to the Secretary-Treasurer was then discussed, and it was resolved that the sum of one hundred dollars per annum be granted to the Secretary, to assist in defraying expenses connected with his office.

The President and Secretary were appointed a committee to revise the catalogue of fruits, and prepare a report similar to the report made in 1863, and submit the same at some future meeting.

The Secretary was instructed to place a copy of the printed declaration in the hands of each of the Directors, to be used in obtaining new members. The Treasurer was instructed to place the funds he may have in hand on deposit, upon the best terms he can negotiate.

The Secretary was instructed to prepare the Annual report of the proceedings of the association; also to compile the reports of the fruit committee, and the discussions at meetings, and to submit the same at the annual meeting to be held in the Court House, Prince's Square, Hamilton, on Tuesday evening, the 22nd inst., at seven o'clock.

The annual meeting of the association was appointed to be held at St. Catharines, on Tuesday, the 13th day of October, 1868, at eleven o'clock a. m., to be continued through the day and evening, the subjects for discussion to be the following:—

Apples.—The best varieties for market; new varieties; picking and packing for market.

Plums.—Best varieties, and the best methods of preventing the black-knot, curculio, and other insects.

Evening session meet at seven o'clock.

Grapes.—The best earliest variety; the best varieties for market; soils adapted to the several varieties; pruning and training.

The Secretary was instructed to embody in the annual report the articles addressed to the Board on "Hybridizing," on "the Phialdelphia Raspberry," and on "the Codlin Moth or Apple Worm."

The Board appointed Wm. Saunders, Esq., of London, Entomologist to the Association, and directed that his reports on insects injurious to fruits, which may be addressed to the Directors, be sent to the Canada Farmer for publication.

The Secretary was instructed to inform the members of the association, through the reports of proceedings, that any member of the association is at liberty to send (*charges pre-paid*) any specimens of insects to Mr. Saunders, at London, which may be found injurious to any of our fruits, by preying upon foliage, fruit, flower or stem; and that while Mr. Saunders is willing to receive and examine these insects, and report thereon to the association, no member will expect that Mr. Saunders shall be put to expense in the transmission of such insects to him, or in replying to any communications respecting them.

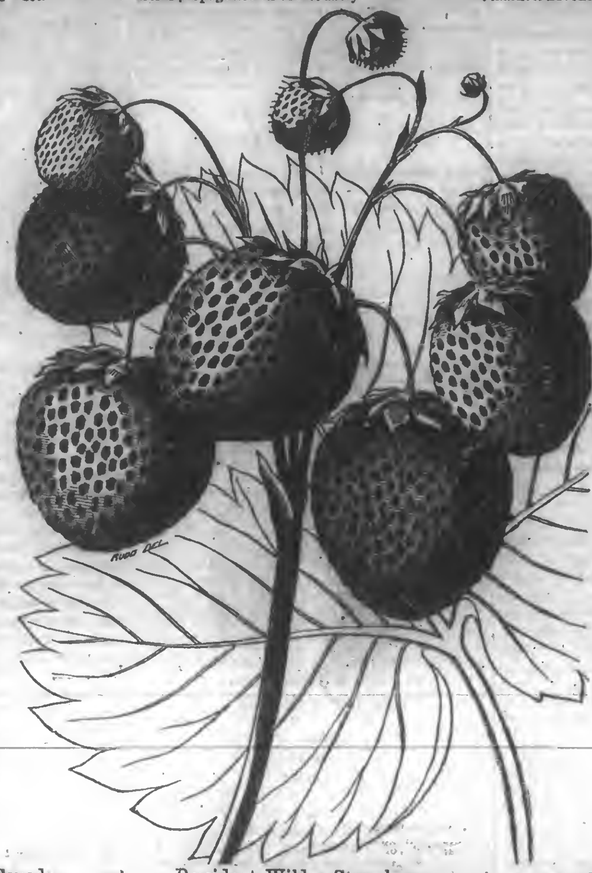
The Board then adjourned to the call of the President.

During the next season I intend to graft two thousand, hoping to confer a real benefit to orchard keepers by scattering them over the New Dominion.

THOS. HOOPER.

Columbus, Sept. 3.

Note by Ed. C. F.—We commend the enterprise of our correspondent and wish him all success. The specimens sent to us were beautiful looking apples, of a creamy colour, somewhat pear shaped, and of moderate size. They are fall fruit, not adapted for keeping. Flavour is a matter of individual opinion, but to us they appeared deficient in this respect, owing in some measure, no doubt, to over-ripeness. Some winter apples, since received from Mr. Hooper, are of beautiful appearance and excellent flavor, especially adapted for cooking, and well worthy of careful propagation in this country.



English Apples in Canada.

To the Editor of The Canada Farmer:

Sir,—Believing that the merits of English apples are not yet well known, and that the most valuable kinds do well here, I imported fifteen different grafts, four years ago last winter. I beheaded several native apple trees, forming a union between the English and Canadian fruit trees. Though these trees stood on the north side of an orchard and were perfectly exposed, yet I have not had one shoot cut back by the frost.

One of the kinds "English Stubbard" (specimens of which I forward) bore fruit the second, third and fourth seasons, and in such abundance as to astonish my friend, S. Roberts, Esq. I counted forty on two grafts.

President Wilder Strawberry.

We have much pleasure in presenting our readers with the accompanying illustration of a new variety of strawberry, the name of which, and the history of its production, are in themselves no small recommendation. Its repute is high in the State where it was raised, but how far it would prove suitable to the climate of Canada remains to be seen. We are indebted for the illustration to the courtesy of the publishers of the *Journal of Horticulture*, from the September number of which we also extract the description of the strawberry, and in doing so, would again commend this beautiful and admirable journal to the notice of our readers. The type and illustrations are in the best style, and the reading matter, to which some of the best horticulturists in America contribute, is interesting and instructive. The journal is published by J. E. Tilton & Co., Boston.

The following is the account of the Wilder strawberry:—"The plant is hardy, robust, vigorous, and very productive. The foliage is handsome and well developed; leaf dark-green, roundish, obovate, deeply serrated, of great substance, with stiff, short foot-stalks, and stands the extremes of heat and cold without injury. The flower-stalk is stiff and erect, the flowers perfect. The fruit is large, some specimens attaining to more than five inches in circumference; and many berries this year weighed more than one ounce avoirdupois each. Their colour is a brilliant crimson scarlet; form obtusely conical; the flesh rosy white, very juicy, but sufficiently firm for market; flavour rich and sprightly, inclining to sweet, with a distinct aroma of the Alpine or wood strawberry; seeds small; season late.

This variety was produced in 1861 by Mr. Marshall P. Wilder, from artificial impregnation of Hovey's Seedling with La Constante, the best two varieties, perhaps, that are now under cultivation; La Constante being the best of the foreign kinds ever brought to this country, and Hovey's Seedling being too well known to need any further mention.

For perfection of form, flavor, and brilliancy of color, combined, this strawberry exceeds anything that has been produced for a long series of years.

Mr. Wilder has been at work raising seedlings for thirty years; and although he has obtained several good ones, he never yet has got one with which he is so completely satisfied as he is with this. The description we have given above is, we believe, in substance, the description settled upon by the fruit committee of the Massachusetts Horticultural Society; to whom the question of a name was submitted, and who have called the strawberry "President Wilder." We have no doubt that it will keep Mr. Wilder's memory green for years and years to come; or that, as soon as it becomes known, it will take the highest possible rank among strawberries, and perhaps supplant everything else."

S. E. Tilton & Co. have, we understand, purchased the whole of Col. Wilder's stock, for distribution among the subscribers to the *American Journal of Horticulture.*

☞ The annual meeting of the Fruit Growers' Association will be held in the Court House Hamilton, on Tuesday, 22nd September, at 7 o'clock, p. m.

☞ All wrinkled peas, says an exchange, are superior to, and more delicate in flavor than those that present a full and perfect form; like sugar corn, the saccharine matter which they contain causes them to shrivel when dried.

Ever-Bearing Raspberries.—M. L. Dunlap says he travelled much in his time, and sat at the tables of a good many prominent horticulturists, but never was so fortunate as to find these autumn berries on any of them. He adds:—"I don't want to prevent gentlemen who can from furnishing us with such fruit; but I do want to prevent the expectations of the public being raised too high by them."

Entomology.

Specimens from a School Girl.

To the Editor of THE CANADA FARMER:

SIR,—I send you three beautiful specimens of insects. I hope they will prove interesting to you, and if so, I would like to see them re-produced in pictures in your paper, as I have often seen before. The spider I found on some scarlet beans; the moth in my bedroom; and the curious fly on a girl's hat.

I remain, Sir,

Yours respectfully,

A SCHOOL GIRL.

Mimico, September.

NOTE BY ED. C. F.—We were much pleased at receiving the above note, which was neatly and clearly written, from some fair young correspondent. We trust that her example will be followed by others amongst our youthful readers who desire to know something about the many beautiful and curious things in nature. The study of Natural History in any of its phases, no matter whether the attention is turned to ferns or flowers, insects, fishes, or birds, is, we feel satisfied, one of the best means for the improvement of the mental faculties of the young; while at the same time it renders all the common objects in the world around us sources of pure and unalloyed interest and delight. In the words of Kingsley, in his "Glaucus,"—"I have seen the young London beauty, amid all the excitement and temptation of luxury and flattery, with her heart pure and her mind occupied in a boudoir full of shells and fossils, flowers and sea-weeds, and keeping herself unspotted from the world by considering the lilies of the field, how they grow."

The spider sent us is a very beautiful black and golden-yellow specimen of these usually rather repulsive creatures. Its Latin name we do not know, as we have not made a special study of these useful animals. We do not suppose, however, that our correspondent has any particular anxiety to be enlightened on that point. The moth is called the Crimson Underwing (*Catocala concumbens*, Walk.). When its wings are closed, it presents the appearance of a flat mottled-gray triangle, very like the bark of the trees on which it reposes during the daytime; but peep at its underwings, and then you will see what a thing of beauty it is—they are of a rich crimson colour, with a broad black band across the middle, and a black border fringed with white. There are about twenty different kinds of these moths in Canada, some with the underwings of various shades of red, some of yellow, some white, all having one or more bands of black, while others, again, have these wings entirely black above, but with the usual bands beneath. The fly is one of those commonly called "May Flies," (*Ephemera*); they have light, gauzy wings and slender bodies, with long antennæ in front, and two excessively long tails behind. In their first stages they live in the water, some say for as long as three years, but when they obtain their wings, they live but for a single night, coming out at sunset, and dying the next morning; a few stray specimens, however, live sometimes for ten days or a fortnight. Early on a bright summer morning we have occasionally seen tens of thousands of them dancing merrily in the sunshine over the shore and shallow margin of the lake; up-and-down, up-and-down they go, enjoying their short existence to the utmost. We must defer any illustration of these interesting creatures for another occasion.

☞ The coffee trees in Madras and that part of the East Indies are greatly troubled with the coffee borer, an insect similar to the borers we have had in the acacias.

The Horned Corydalis, or Shad-fly.

IN our issue of Aug. 1, we mentioned the receipt of a communication from Mr. Walter Tait, of Beverley, accompanied by a specimen of the female of this insect. (We regret that by a typographical error the name was mis-spelt "Chad Fly," instead of "Shad Fly.") He writes as follows:—"Enclosed I send for your inspection, an insect, which from its peculiarly ferocious appearance, has excited the curiosity of every one who has seen it. Never having met with an insect of the same kind during a ten years' residence in Canada, nor found among old settlers one who had seen such a specimen, I thought that perhaps it might be a native of some tropical country, which, in consequence of the unusually hot weather we have had, may have migrated to our usually more temperate region." The terrible hot weather of July was certainly tropical enough to warrant us in expecting the advent of any monsters dire from the regions of the equator; the specimen before us, however, of which we give an illustration, is not to

be classed among these, notwithstanding its portentous aspect, but is a veritable native of Canada. We have taken them from time to time ourselves, and have occasionally had them brought in to us by astonished captors, who not unnaturally deemed that they were prodigiously valiant in venturing to touch such a horribly ferocious-looking animal. Its looks belie it, however; for, though so big and formidable in appearance, it is one of the most harmless insects that we have. It belongs to the order *Neuroptera*, which includes also Dragon-flies and other net-winged insects—and is called the *Corydalis Cornutus*. Its larva is a broad flat worm with six legs, and a row of long spiny filaments on each side of its body, living in the water and preying upon various aquatic insects. When about to assume the pupa state, it crawls out of the water and hides itself under some log or stone on the river-side, where it is often found by fishermen, who make use of it as bait, and call it by the expressive name of "crawler." It takes about three weeks to arrive at its perfect state, and then it comes out with huge wings to fly about at night, and provide for the due arrival of a new generation. The jaws of the female that we have figured are by no means small, but they are nothing when compared with those of the male, which, to use an expressive phrase, are "a regular caution," being about an inch long, curved, and crossing each other in the middle like a pair of scissors!

An Emperor Moth's Cocoon.

We have received from "B," who writes from Kincardine, Co. of Bruce, a tin box, enclosing a carefully packed specimen of an Emperor Moth's cocoon. It was found, he states, "firmly fastened to the branch of an apple tree, and so securely did it adhere with its parchment-like covering that it required considerable effort to detach it;" as he had never seen anything like it before, he sends it to us for identification.

This pod-like cocoon, formed of strong silken fibres so firmly agglutinated together as almost to resemble parchment in texture, is the last stage but one in the life of one of our largest and handsomest insects—the Cecropia Emperor Moth. The caterpillar, which is hatched from a round, flattened, brown and white egg, is, when fully grown, a huge, fat, humped worm, three or four inches long, and thicker than a man's thumb; it is of a beautiful green colour, adorned with singular blue, yellow, and coral-red warts on the back. It feeds on the leaves of apple, plum, cherry, and numerous other trees, to a twig of which it attaches its cocoon when done feeding, and there it remains, exposed to the frost and snow, and bitterest blasts of winter, unaffected by them all, ready to come out a beautiful winged moth when genial June comes round again. This moth is the largest insect we have in Canada, its wings expanding to a breadth of six or seven inches. We shall not describe it particularly now, as we purpose giving an illustration of it before long.

Poultry Yard.

Fancy Pigeons.

To the Editor of THE CANADA FARMER:

SIR,—Perhaps a few more observations on the Pigeon tribe may not be unacceptable to your readers. I am afraid I cannot offer anything new, or that may not be found in Tegetmeier's, Eaton's, or other modern works on the subject; but I have found few, even of those who call themselves fanciers, in Canada, know anything, or comparatively anything, about it.

As a rule, the specimens of pigeons exhibited and kept in Canada are very inferior. I hope I may not "catch it" for this sweeping condemnation, but it is truth, and the sooner told the better; and my advice to those who are inclined to keep pigeons is to clear their lofts of all their rubbish, and invest in a *few* pairs of the correct specimens, by importation from England. Perhaps it would be as well to give an illustration of my meaning by reference to a few kinds. I will begin with Carriers. Well, with the exception of my own, I do not think I have seen a Carrier since I left England. I have seen one or two Horsemans, and very indifferent Dragons. Unsophisticated persons are very apt to call all these birds Carriers, but a true genuine English Carrier is a fancy bird, very hard to obtain; and to keep them up to the standard is still harder. Great circumspection is required in the selection of breeding stock and matching; and the worst is that neither this nor any good stock can be had without paying very high prices, not justified at present by the demand for them. But then it is useless having inferior stock; so that it is simply do without, or pay the price; and it will then take from three to five, and on to nine years, to get up such studs as I have seen at Hayne's Potter's, &c. There is one good thing about them,—they are, as a rule, good nurses, and take care of their young; and my experience of Canada is that it suits them. The atmosphere takes liberties with their plumage, especially the "dun;" and due allowance must be made for this at exhibitions. Indeed I know of no bird harder to judge in close competition. For the points of these birds I must refer you to Tegetmeier's Pigeon Book; it would take up too much time and space to enter into them here.

These remarks will apply in many points also to Pouters, few good specimens being seen. You will find a bird with a large crop, and no legs, short tail, &c., and no length. The first point in a Pouter is length of leg, or limb, as it is called; then length of body or feather, and crop, and last of all, I say, colour. You will find well-marked birds in Canada, but you will require to be told they are Pouters or you would not know it. I put colour last, on the principle that a good horse cannot be a bad colour, nor a good Pouter either.

With regard to *Tumblers* of the common variety, I believe there are some good specimens, as far as tumbling and flying are concerned. There are some fanciers in Montreal who train their flights. I should say the colour is mostly indifferent, but I have seen some, though only a few, very good as to colour, especially Almonds. Bald-heads are few and far between; Beards are better. It will perhaps more plainly illustrate the real *status* of these birds by saying that any like them could be purchased in England for three shillings a couple.

As for *Short-face Tumblers*—where are they? There are a few attempts at them, but the real thing I have never seen since I left the old country.

The *Jacobins* to be seen in Canada are too large, mousey-headed, long-faced things, often odd-eyed, bad coloured, and inferior in the hood and chain. There are very few good, if any.

At some future time I may resume the subject, if you think these remarks of sufficient interest to your readers.

F. C. HASSARD.

Roup in Fowls.

A SUBSCRIBER, from Paris, sends the following communication:—"About a week ago, my fowls were attacked by a loathsome disease, the symptoms of which are running at the nose, watery eyes, dull appearance and gaping. Can you or any of the readers of your paper give me a cure for it, and tell me what disease it is, and how game fowls are more subject to it than any other class of fowls?"

The disease described by our correspondent is a very common, contagious and fatal disorder, called roup. We are not aware that it is at all more prevalent among game fowls than any other variety. We are sorry that we cannot say much on the subject of a cure for this troublesome complaint. If the fowls are not very valuable, it is almost better to destroy them than undertake the trouble of the cure, or run the risk of the spread of the malady. We will give our correspondent, however, the benefit of Tegetmeier's remarks on the treatment of such cases.

"Warm, dry lodging, and stimulating, nutritious food, are the first essentials to recovery, in addition the frequent removal of the dried discharge from around the eyes and nose, by warm bathing, must not be omitted. In the way of internal medicine, I find that nearly equal numbers recover under various modes of treatment. I have tried the following remedies, viz.: iodine in tincture, mercurial ointment, and nitrate of silver, all applied externally to the sides of the face, without any advantage. Internally I have given calomel, sulphur, citrate of iron, calomel and opium, cayenne pepper, and sulphate of copper, without any very well-marked or decided improvement. The direct application of some remedial agent to the diseased membrane promises the best result; but here we are met with the difficulty as to the application, for the nostrils are closed up and it is nearly impracticable to pass anything through them. A very small bent tube can, however, be readily passed into the cavity of the nose through the slit in the roof of the mouth; and I have tried the effect of injecting a few drops of a dilute solution (ten grains to the ounce of water) of sulphate of copper, with very favourable results. The injecting tube is readily passed into each nostril, if inserted into the anterior part of the slit seen in the roof of the mouth, and directed outwards at right angles to the slit.

"In very severe chronic cases, when there has been much swelling of the face, I have opened the side of the face, and removed the diseased secretion in a solid form."

Standard of Excellence in Exhibition Poultry.

CREVE CŒURS.

THE COCK.

Crest—As in Polish Cock, but perfectly black; white feathers a defect, but not a disqualification.
Head—As in Polish Cock.
Comb—Brilliant red, two-horned in shape, but free from tynes; slightly sprigged at base, of good size, showing well in front of the crest.
Eye—Full, bright, and very vivacious
Deaf-ears—Small and nearly concealed.
Face—Red, well muffled.
Wattles—Moderately pendulous, and evenly rounded, brilliant red
Muffling—Close and thick, running to back of the eye in a handsome curve.
Beak—Black, with horn-coloured tip, strong and well curved, with highly arched broad nostrils, as in Polish.
Neck—Moderate in length, thickly hackled, well arched, and carried a little back.
Breast—Broad and full, carried well forward.
Back—Wide, perfectly straight, and free from deformity.
Body—Long and square.
Wings—Closely set and well clipped up.
Tail—Full and ample, well sickled, and carried rather erect.
Thighs—Rather short, well set in body.
Legs—Black or slate; shorter the better, rather fine in bone; free from feathers.
Carriage—Upright, smart, vivacious, and watchful.
Colour—Brilliant black; red or straw feathers in the hackle and saddle undesirable, but not a disqualification.

THE HEN.

Crest—Full and globular, as in the Polish black; white feathers objectionable, but not a disqualification.
Head—As in Polish.
Eye—Full and bright.
Deaf-ears—Small, hidden by muffling.
Muffling—Thick and full, extending well back to crest, and forming a thick beard under the beak.
Wattles—Very small, and neatly rounded.
Neck—Thick and arched.
Breast—Full, plump, and carried well forward.
Body—Square, carried low.
Back—Straight and broad.
Wings—Well clipped up.
Tail—Large and well expanded.
Thighs—Short and well set into body.
Legs—Short as possible, free from feathers, rather small in bone, slate or black in colour.
Carriage—Upright and vivacious.
Colour—Brilliant black; a brown tinge very undesirable.

POINTS IN CREVE COUR.

Size	4
Crest	3
Shape and symmetry	2
Colour	3
Condition	2
Comb	1
	15

DISQUALIFICATIONS.

Deformity of any kind.
Coloured feathers elsewhere than in crest, neck, or saddle.
Feathered legs, and shanks of any colour than black or slate.

HOUDANS.

THE COCK.

Crest—Composed of hackle feathers; full, and well arched, falling back, and right and left of comb, clear of the eye rather than over it.
Comb—Well developed, large, red and branching, broad at base, well indented, looking like a mass of coral with antler-like branches, inclining rather backward into the crest.
Beak—Curved, with nostrils wide and cavernous, as in Polish; dark brown colour.
Eye—Large, full, bright, and lively; colour, various.
Wattles—Thin, rather long, neatly rounded, and bright red.
Muffling or Beard—Full and thick under beak, and reaching well back in a curve to the back of eye.
Face—Red; less seen the better.
Breast—Deep, full, and plump.
Back—Wide and straight.
Wings—Moderate, and carried well up.
Tail—Moderate, erect, and well sickled.
Thighs—The shorter the better.
Legs—Fine in bone, white or shaded.
Toes—Five in number, the fifth curved upward at back.
Colour—Broken black and white, as evenly broken as possible; free from coloured feathers, which, however, though objectionable, are not a disqualification.
Carriage—Lively, brisk, well set up and spirited,

THE HEN.

Crest—Large, compact, and even, as in Polish.
Comb—Small, branching, and coral-like.
Eye—Full and bright.
Wattles—Small, red, and neatly rounded.
Muffling—Full, forming a thick beard reaching back to the eye.
Neck—Rather short; full feathered and arched.
Breast—Full and deep.
Back—Wide and straight.
Wings—Moderate, and carried close to the body.
Tail—Moderate, and fan-like, carried well up.
Thighs—Short.
Legs—Fine in bone, white or shaded in colour.
Toes—Five in number, the hind or fifth claw curved upwards.
Colour—As in Cock.
Carriage—Brisk, and rather upright.

POINTS.

Size	4

Plumage	2
Condition	2
Five claws	1
	15

DISQUALIFICATIONS.

Absence of crest.
Deformity of any kind.
Main colour or ground colour other than black and white.

LA FLECHE.

THE COCK.

Beak—Black, strong, and curved; nostrils wide and cavernous, as in Polish, with small spot or knob of bright red flesh at junction of nostril with beak.
Comb—Branching and antler-like, like two horns pointed straight up, brilliant red.
Ear-lobes—Large, and as white as possible.
Head—Long.
Eye—Bright, large, and watchful.
Face—Red, and rather bare.
Wattles—Red, long and pendulous, well rounded.
Neck—Long, rather curved, and upright; hackle thick, but rather short.
Back—Very long and broad, slanting towards the tail.
Wings—Long, and well clipped in.
Breast—Broad, and rather full.
Tail—Rather small, and carried low.
Thighs—Strong, long, and well set into body.
Legs—Long, strong, and black or slate in colour.
Toes—Four.
Plumage—Close and hard, brilliant metallic black
Carriage—Very upright, dignified, and watchful.

THE HEN.

Beak—Black, strong, and curved; nostrils arched, broad and cavernous.
Comb—Double-spiked and branching, standing well up, or the branches inclining a little forward, small.
Head—Long.
Eye—Bright and watchful.
Face—Red and rather bare.
Deaf-ears—Small and white.
Wattles—Red, small and neatly rounded.
Neck—Long and straight.
Back—Broad, and tapering towards the tail.
Body—Wide and deep.
Breast—Very broad.
Wings—Large, and well clipped up.
Tail—Small in proportion, but well expanded, and carried upright.
Thighs—Long and well set into body.
Legs—Long, well boned, black or slaty in colour.
Plumage—Brilliant metallic black, close and hard.
Carriage—Upright, dignified, and watchful.

Correspondence.

Queries from a New Settler.

A CORRESPONDENT requests answers to the following list of queries:

1. Which do you consider the best farming districts in Ontario?

2. Can a first-class cleared farm be had on lease, as in England, say for a term of seven, fourteen, or twenty-one years?

3. What capital would be required to properly work and stock a farm of 150 or 200 acres, and about what profit ought to be made on the capital after deducting expenses?

4. I spent, say the first fifteen years of my life on a first-class farm in England, have had experience in three counties in England, have a general, thorough, I don't profess *perfect*, knowledge of stock, arable and pasture farming. Would my previous experience be advantageous to me in this country, or not?

5. The style of farming I should pursue would be that of some of our best Canadian farmers, always keeping a sharp eye to the minor matters of the concern, purchasing my stock with a view of their growing into money, rather than keeping them for show, avoiding, at least for the present, anything like model or scientific farming, but rather endeavouring to conduct my business as a well managed mercantile concern ought to be conducted, viz: to pay for labour and capital. Do you think I should succeed?

6. What time of the year is the best to take possession of a farm?

ANS.—In offering our replies to the above queries, we must premise that the questions are so general and cover so much ground, that it would require a treatise on Canada to answer them fully. Moreover, he brings up the unsettled question as to which is best, the eastern section of Ontario, from its proximity to market, or the western section, from its supposed greater fertility.

(1.) Each section has its adherents, who think that nothing can equal their own homes. We must therefore recommend personal enquiry in the several districts. Each man applied to will probably urge the claims of his own locality, bringing forward the best arguments in its favour, and leaving out of sight perhaps its disadvantages. For these the enquirer must make due allowance.

(2.) First-class farms can be leased all over the Province on excellent terms for the tenant. Rents range from $1.50 to $4 per acre, according to the amount of cleared land, the value of the buildings, and the proximity to market.

(3.) Hundreds of tenants in Canada lease improved farms of 100 to 200 acres on a capital of from $400 to $2,000. In Canada, as in England, the more capital a man has on his farm (provided common prudence is used) the better he will succeed. There is no stated rule here as in England, stipulating for a certain minimum amount of capital in proportion to the number of acres to be leased.

(4.) Knowledge of English farming, and a competent judgment as to cattle, horses, and sheep, are always an immense assistance to a man commencing farming in Canada. Indeed, if his practical acquaintance with land and stock is yet to be acquired, he had better not buy a farm.

(5.) We cannot pass an opinion on this head without some personal knowledge of the querist. But we can see no reason why he should not succeed, nor why he should start with the determination of eschewing *scientific* farming.

(6.) The end of winter, or early in the spring, say 1st of March, is a common time to enter on a farm, but there are many advantages in taking possession in September or October. The land is often left in poor condition by a tenant who does not contemplate remaining, and who does not therefore think it worth his while to fall plough or manure. The incoming tenant, if he enter in the fall, can attend to these matters himself, and has time to get settled in his new home before the hurry of spring work begins.

Caution to Smokers.

A Simcoe paper gives the following account of an accident from carelessness in smoking:—"A farmer in Windham, who was hauling in oats last week, while seated on the load with two little boys, used a match to light his pipe. The match was thrown away apparently extinguished, but directly after it was discovered that the load was on fire. The horses then ran away, a perfect stream of fire pouring from the oats. The farmer was thrown from the load, but the little boys clung to it. The horses were at length stopped by some parties on the road, when they were detached, and the boys rescued from the burning load."

To this our correspondent "Denizen," who sends us the above clipping, adds "another caution to smokers" from his personal recollection. He writes:—"About twenty-five years ago, a farmer driving down Queen street, Toronto, set fire to his load of hay by a spark from his pipe; he was driving pretty fast with a stream of fire in his rear. Passers-by called out and warned him of his danger; but the moment the horses came to a halt the whole load became enveloped in flame, so that he barely escaped with his life. The horses were both ruined by the fire, and could only be liberated by cutting the hame straps and leading them out of their harness. When I saw the place a few hours after, nothing remained to the poor farmer but his horses, and they dreadfully burned, with hardly a hair left of their fine flowing tails, and a pile of old tires and irons from the waggon and harness."

COMMUNICATIONS DEFERRED.—Several communications, received too late, or for want of space, are unavoidably postponed.

The Canada Farmer.

TORONTO, CANADA, SEPTEMBER 15, 1868.

New England Agricultural Fair.

[EDITORIAL CORRESPONDENCE.]

NEW HAVEN, Connecticut,
Sept. 4, 1868.

THE fifth annual exhibition of the New England Agricultural Association, an organization embracing the whole of Yankeedom, properly so called, commenced here on the 1st inst., and closes to-day. As this is one of the handsomest cities in the United States, and owes its beauty chiefly to its rural adornings, a brief description of it will not be inappropriate by way of preface to some account of the fair. New Haven occupies a beautiful plain, at the head of New Haven Bay, four miles from its entrance into Long Island Sound. It is 160 miles south-west of Boston, and seventy-six miles north-east from New York, being in a direct line between the two cities. The plain on which New Haven is built slopes gently toward the water, and is environed on all sides except in the direction of the harbour by hills, two of which, called East and West Rocks, are very rugged and precipitous, rising almost perpendicularly from 300 to 400 feet in height. Three small streams flow across the plain, emptying into the bay. They are bridged at several points, in one instance with a draw-bridge, which leads from the steamboat landing to East Haven. The streets are usually four rods wide, intersecting each other at right angles. Those on which the best private residences are built exhibit a particularly neat and elegant appearance, from the fact that the dwellings are for the most part detached, and surrounded with shrubbery and gardens, which are tastefully laid out and well kept. Hill House Avenue, a delightful suburb, is a paradise of foliage and flowers. But the crowning glory of New Haven is its noble and lofty elms. These have long given it the appropriate designation of "Elm City" and "The City of Elms." The principal public square, comprising about sixteen acres of land, is bordered with majestic elms, and crossed by avennes, on each side of which is a row of the same trees. One whole side of this magnificent square is occupied by "Yale College" buildings. This is one of the oldest and most renowned of the many educational institutions in the United States. The College buildings have for the most part no architectural attractions, consisting of eight plain brick edifices, five of them four stories high, containing study and sleeping rooms for the students, and the other three, each surmounted by a tower or spire, being the chapel, observatory, and lyceum. In the rear of these plain buildings are some of more modern erection, that have some architectural pretensions. Chief among them is the library, a costly and handsome Gothic structure, (fire-proof), 150 feet in length. The Medical College, a handsome granite structure, stands a short distance farther off. The other three sides of the great square are occupied by stores, hotels, churches, and private dwellings, while actually on the square stands the State House, a large stuccoed building, modelled after the Parthenon. Nothing can exceed the beauty of the elms. No wonder they are the pride of New Haven. Whether singly or in rows, the elm is a grand tree, its variety of shape, and gracefulness in every part of its outline, giving it an indescribable charm. There is hardly any other forest tree that, planted as these are, without intermixture with other trees, would not look monotonous. If this fine elm-bowered square were surrounded by log-houses or shanties it would still be a charming spot. It is not from costly architecture that this scene derives its loveliness, but from so cheap and universally practicable a thing as tree-planting. We have often advocated this means of imparting beauty to country homes, villages, and towns, but no language we can find can do justice to the example of its effect as seen in this city. To give our readers some faint idea of a scene which perhaps few of them will ever have the privilege of beholding as we have done, we present herewith a couple of engravings prepared by our artist from photographs. The first represents College Street, with Yale College buildings on one side, and the State House on the other. The second engraving shows Temple Street, the finest of all the elm-arched avenues that cross the square. Did ever series of Gothic arches present so magnificent a perspective as this double row of elms? Yet there is not a village in our land that might not have in time just such a natural archway, if the population would only plant trees. The early settlers in New Haven, by whom the trees were planted, have left an enduring monument behind them which will keep their memory green to the end of time. There are some exceedingly fine public buildings and private residences in New Haven, but it is the concurrent testimony of all who have been here, that this place owes more to nature than to art, and that its chief charm arises from what might adorn the humblest and most unpretentious cottage home.

But to the fair. It is held in Hamilton Park, a very convenient spot, about a mile and a half from the heart of the city. The exhibition consists of two departments, the agricultural show, properly so called, and THE RACES. It is most extraordinary to what an extent the horse-racing mania has got the ascendency in the New England Agricultural Association. The managers of the concern seem to be possessed with the idea that without the races they cannot make the annual fair pay. Hence they not only tolerate, but encourage this objectionable appendage, even to the extent of allowing gambling pools to be openly sold at auction. The same unscrupulous greed which admits racing has led to the licensure within the grounds of such a collection of wretched catch-penny side-shows as we never saw

huddled together before. It is said that a couple of lawyers once went into partnership in the city of New York, whose names, when associated on the "shingle" they stuck up, read "Catchem & Cheatem." This is probably apocryphal, but it would really seem as if Catchem and Cheatem were the presiding spirits at this exhibition, in the very heart of steady-going New England. The determination to make the thing "pay" seems to have been the ruling purpose, without much regard to the means whereby the end was to be brought about.

The combined attractions of agricultural fair, races, and side-shows, have proved irresistible to a large number of people. It is estimated that from 20,000 to 25,000 people were on the ground yesterday. The charge for admission to the grounds is fifty cents each and every time, to all non-members. Beside this, admission to the grand stand, where some thousands can have a good view of the racing, is twenty-five cents extra. What with members' fees, admission tickets, grand stand charges, side-show licences and the sale of gambling pools, quite a pile of money must be scraped up. But certainly the keen dealers in basswood hams and wooden nutmegs, and the class of people concerning whom it is proverbial that they and their money are soon parted, have not as yet all emigrated from New England to parts unknown.

Barring the objectionable features just referred to, the agricultural display is a good one, and it says very little for the intelligence and public spirit of New Englanders, that such an exhibition would not draw a large attendance of visitors without racing and gambling appendages.

[THE LIVE STOCK.

There is a large muster of horses, chiefly, however, of the carriage and roadster classes. Some spans are beautifully matched, and really magnificent animals.

Single horses too, of very fine appearance, are numerous. The race-horses are not much to look at, but are lanky, ill-proportioned brutes, almost without exception. Eleven thorough-breds are exhibited; seven of them the property of W. W. Chenery, Belmont, Mass., and among them are some remarkably good specimens. The general purposes class of horses is well filled, and for practical utility, both on the farm and road, they are all that could be desired. A number of highly promising colts are also shown. The cattle department, as a whole, is in advance of anything in that line which we remember to have seen at any fair in the United States. We certainly did not expect to find such an array of Short-horns. Some of the choicest specimens of the Dutchess blood, and other favourite strains, are here. Mr. H. M. Arms, of Springfield, Ill., shows a fine herd, recently purchased by him of Mr. Burdett Loomis, of Windsor Locks, Ct., who having resolved to concentrate his attention on sheep, sold the valuable collection of Short-horns he had been carefully getting up for some years. Among them are "6th Duke of Thorndale," and his son by "2nd Lady of Oxford," "4th Lord Oxford," "Tyke," a three-year old heifer, and "Gem of Stony Brook," all very choice animals. Messrs. A. J. Cass, Holliston, Mass.; B. Sumner, Woodstock, Ct.; C. Spooner, Bridgeport, Ct.; A. M. Winslow and Sons, Putney, Vt.; and A. W. Griswold, of Morrisville, Vt., also exhibit in the Short-horn classes. The last named gentleman shows "14th Duke of Thorndale," of which he is the fortunate owner. Devons are out in strong force, the chief exhibitors being Harvey Dodge, of Sutton, Mass.; E. H. Hyde, Stafford, Ct.; Stanley Griswold, Torringford, Ct.; and W. Mattoon, Springfield, Mass. A very noticeable feature among the Devons are the working oxen. New England farmers wisely make large use of oxen as well as horses, and Devons or Devon grades are the favourites for working cattle. The display in this class is something remarkable. One exhibitor, Marshall H. Day, of Chesterfield, N. H., shows two pair of twin cattle all from the same dam, a good native cow, and sired by a Devon Bull. These four oxen are wondrously alike. Each pair is perfectly matched. One pair, five years old, weighs 3,900 lbs., and the other, seven years old, weighs 4,200 lbs. The younger team is valued at $600, and the older one at $700. A pair of Durham grades, owned and exhibited by the same individual, and weighing 3,800 lbs., is valued at $500. Those who have only seen the ordinary style of ox teams, rough, scrubby, unshod and unkempt, can have no idea of the fine appearance presented by a first-class New England ox team, groomed, shod, and trimmed up, like a stylish pair of horses. Besides the full-grown Devon and grade oxen, there is a very fine display of steers. The Alderneys and Ayrshires are numerous and of prime excellence. Messrs. Converse and Flagler, of Arlington, Mass., exhibit two Alderney cows, "Lady Milton" and "Cream Pot," that gave an average of *nineteen quarts* of milk each daily, during the month of June last, from which an average of two lbs. twelve oz. each of butter was made; or *twenty pounds* per cow, weekly. Messrs. Wallace Barnes, of Bristol, N.J.; John Brooks, Princeton, Mass.; Thos. Fitch, New London, Ct., are, in addition to the firm already mentioned, the chief Alderney exhibitors. Ayrshires were shown by Messrs. H. S. Collins, of Collinsville, Ct., and W. Birnie, of Springfield, Mass., both of whom have large and fine herds; also by S. M. & D. Wells, of Wethersfield, Ct., and Thomas Fitch, of New London, Ct., who have some excel-

STATE HOUSE AND YALE COLLEGE BUILDINGS, NEW HAVEN.

TEMPLE STREET,—NEW HAVEN.

lent animals. The last named gentleman shows some fine Alderney and Ayrshire Grades. Dutch or Holstein cattle are exhibited by Mr. W. W. Chenery, of Belmont, Mass., who has no fewer than twenty-six head of these cattle on the ground. They are clumsy and rather coarse-looking animals, invariably black and white, mixed and mottled; the cows, from the size of their bags and escutcheons, ought to be good milkers, but we do not know of any special advantages they have over other good breeds beyond this, that they illustrate the proverb, "variety is pleasing." There are some excellent specimens of native cows, that we should take to be fine milkers. Two side shows of extra fat cattle invite the patronage of visitors. One of "Lady Hampden," three-fourths native and one-fourth Short-horn, said to weigh 4,060 lbs., and the other of "Gen. Grant," a seven-eighth Durham ox, pure white, reputed to weigh 5,100 lbs., and owned by Carlos Pierce, Esq., Derby, Vt. The show of sheep is very fair, but not so extensive in the Merino classes as might have been expected considering that the fair is held so near Vermont, the paradise of "American Merinos." They are in more than due proportion to the rest of the sheep classes. "Golden Fleece" is here, the marvellous "critter" for which $15,000 has been offered and refused. One does not know whether to regard the offer or the refusal as the greater piece of folly. The owner of this paragon is Mr. E. S. Stowell, of Cornwall, Vt. Messrs. L. J. Wright, of Weybridge, J. D. Wheat, of Putney, and J. Holden, of Westminster, all Vermonters, also exhibit in this class. Mr. Burdett Loomis, of Windsor Locks, Ct., has a very choice and valuable flock of Cotswolds, fifty in all, and among them some costly importations from Messrs. Garne and Lane, and other noted English breeders of Cotswolds. "Senator," "Sir Robert Napier," and "Duke of Edinburgh" are splendid rams, and are matched by ewes of equal excellence. Mr. Byron Loomis, of Suffield, Ct., cousin of the last named gentleman, is also laying the foundation of a Cotswold flock in some valuable importations which he exhibits. Mr. Sherman Hartwell, of Washington, Ct., has also some good animals of this breed. A few Southdowns of medium quality are shown by Mr. H. L. Stewart, of Middle Haddam, Ct. Mr. Chenery, already mentioned, exhibits a pair of Lincoln sheep, first-prize takers at the Royal Agricultural Show at Bury St. Edmonds. He has also curious specimens of the Caraman or flat-tailed sheep, with huge flat tails weighing thirty or forty pounds; of the Texel or Mouton Flandrin sheep from Friesland; and a pen of very pretty, snow-white Angora goats. Only a few swine are shown, chiefly Chester Whites. There is a pen of Suffolks and another of Yorkshires. The poultry show is very meagre, and only a few of the coops are really good. A patent hen's nest, intended to seclude the hen while laying, is exhibited. When the fowl steps into the nest, a pair of doors, perforated with holes for ventilation, close upon her, and when she steps out of the nest the doors open for her exit. A patent water fountain is also shown, which seems to work well. The patentee of the nest is Mr. Hiram Stevens, of New Haven, Ct., and of the fonntain Mr. R. D. Blinn, Lexington, Mass. Before dismissing the live stock, it will be proper to mention that some artificially hatched trout, a year old last April, and averaging a quarter of a pound in weight, are exhibited. Their size surprises every one. Several parties in this country are now engaged in the breeding of trout, and "fish farming" bids fair to take rank beside "fruit farming" and other modern agricultural improvements. The trout exhibited on this occasion were raised in "Cold Spring Trout Ponds," Charleston, N. H. Spawn may be procured at $8 per 1000, and young trout at $25 per 1000, Am. Cy., by sending orders to that address.

IMPLEMENTS.

A most varied, extensive, and excellent assortment of agricultural tools, machines, and implements is collected, and the briefest mention of all that is worthy of notice would convert this narration into a catalogue. To begin with ploughs, here they are of all sorts and sizes, stubble or old ground ploughs, green-sward ploughs, deep tiller ploughs, self-sharpening ploughs, double mould-board ploughs, sub-soil ploughs, side-hill ploughs, gang ploughs, reversible ploughs, prairie ploughs, and last, but not least, the Doe plough, which took the first premium at the New England Fair in 1867 over sixty-three other ploughs that competed with it. The "Ames Plow Company," of Boston (they reject the "ough" mode of spelling the word) are the chief exhibitors of ploughs, and indeed implements in general. Everything they manufacture is of the very best material and workmanship. They have nothing here specially "fixed up" for exhibition. Everything is just as it is kept for sale in their storehouses. We advise Canadian farmers to send for a descriptive catalogue of what this firm manufacture. The Doe plough is made by Whittemore, Belcher & Co., Chicopee Falls, Mass. Collins & Co., of Hartford, Ct., show some very nice cast steel ploughs. All the standard reapers and mowers are here, and among them the actual machine exhibited by Woods at the Paris Exposition, a very highly finished and sweetly working machine. A large and fine assortment of "Clipper" mowers and reapers is shown. We observed nothing new in this department, and do not expect to do so, until some one invents a binding attachment, which we are sanguine enough to believe will yet be achieved. There are plenty of horse-rakes, the only novelty being "Howard's Carriage Revolving Horse Hay Rake," very much the old style of thing, with wheels attached so that the driver may ride. It is exhibited by S. S. Westbrook, of Kingston, Ulster Co., N. Y. Several styles of hay tedders are shown, and this valuable instrument is evidently growing in favour among American farmers. Webb's improved horse-hoe, made by Dunham & Carrier, of Bangor, Maine, looks like an effective means of saving hand labour. Horse-hay forks are not so conspicuous as they usually are at these exhibitions. The harpoon fork is the only one that caught our eye. Feed cutters are in great variety, among them one which is a revival of the old lever style of thing, but the arm is all of iron, so giving a heavy down stroke. It is cheap, and said to be effective. Certainly there is no machinery to go out of order. Whittemore, Belcher & Co., before named, show this feed cutter, with many more of costlier make. The "Union Horse Power," exhibited by Ames Plow Co., is a very simple, easily-worked, and efficient tread power, on a much more gradual incline than machines of that kind generally are, thus rendering it less toilsome to the animals put on it. Seed-sowers and wheel hoes are shown by Whittemore, Belcher & Co., and others. A new style of farm dumpling waggon is exhibited by the "Dump Waggon Co.," of East Highgate, Vt. It is the best thing of the kind we have seen, and we have inspected several. We shall try to give an illustrated account of this contrivance in a future number, as it is very simple, and capable of being adapted to any ordinary farm waggon. Two novel styles of hand-hoe are shown, one "the adjustable hoe," so arranged that it can be set at different angles to the handle, and the other, "Allen's patent weeding hoe," with a double-edged blade of large saw teeth, said to be "death to weeds." Two inventors exhibit adjustable carriage poles. We prefer the one manufactured by "The Bishop Adjustable Pole Co.," New Haven, Ct. It is strong and well braced, graceful in appearance, and easily fitted to any single or double carriage or cutter. An excellent cattle-tie and ox-bow fastener are shown by an agent of the "Stanley Works," New Britain, Ct.

MISCELLANEOUS.

Dairy requisites have scarcely a place in the exhibition, and churns, which are usually quite a feature at these shows, are conspicuous only by their absence. There is, however, an improvement of the old churn-dash which we think well of. The patent embraces "the hollow-plunger principle," and the "pyramidical, cone, dome, and hat-shape," from which our readers may, perhaps, glean some idea of it. "The Patent Churn-dash Co." of Hartford, Ct., sell it. An invention of some importance to factory dairymen is exhibited. It is "Peck's Milk Cooler," intended to take the animal heat out of milk as quickly as possible. It consists of a coil of zinc or rather metallic tubing, in a sort of half-barrel tub containing ice water. The milk is passed through the tubing, and the thermometer proved that the animal heat is rapidly and completely removed by this process. Fowler & Barnes, of Northford, Ct., sell this machine. We commend it to the notice of Canadian dairymen, as the simplest and best contrivance for the purpose which we have met with. Several descriptions of farm gates are shown, but there is nothing particularly new in this line. Fruit baskets in great variety are exhibited; among them we like best the veneer fruit basket, made by "The Beecher Basket Co.," of Westville, Ct. Nice grape-packing boxes and crates are shown by the "American Basket Co.," New Britain, Ct. "The Atlantic Water Elevator" is a great improvement on the well-known chain pump, by which the tubing is dispensed with, and the water brought up in small galvanized iron buckets, which alternate with long links in the endless chain. A. Austin, Norwalk, Ct., is the maker of this elevator. J. Harris & Son, 76 Kingston St., Boston, exhibit beautiful gilt weather vanes in great variety, suitable for barns, churches, and other public buildings. A patent grapple with a holder, which can instantly, and without a ladder, be attached to a beam or rafter for elevating purposes, is shown by Hawley, McClure & Co., Utica, N. Y. Galvanized iron trellises, neat, light, and pretty, for garden use, are exhibited by W. W. Wilcox, Middletown, Ct. All carriage-makers, and everybody who, owning a wheeled vehicle, would have it run without noise and excessive play at the wheels, will do well to make a note as follows: "Raw Hide Washers, for sale by the Darrow Manufacturing Co., Bristol, Ct." They are the very thing; cheap, solid, absorbing oil enough to lubricate them sufficiently, and yet not softening as ordinary leather ones do. They are made all sizes, from that of the smallest buggy axle to three and a-half inches outside diameter, and cost from $2 to $4 per gross, American currency. The same company make untanned leather doll heads, that look as nice as wax and will bear any amount of knocking about by rumbustical babies. Housewives, attention! here are a few items worthy your notice. A suspension egg-carrier for sending eggs to market, or keeping them at home—each egg being suspended by itself in a little calico bag. We, unfortunately, omitted to make a note where this contrivance is to be had. "Excelsior bread and meat cutter," which cuts a round of bread, cake, or beef-steak, smoothly and of uniform thickness, with mathematical precision. Sold by Corbin and Tarbell, Worcester, Mass. A patent mincing knife, which gives not only the guillotine stroke, but the drawing stroke. This is a very nice kitchen tool, price $1.50, and made by Ketchum & Lond, Winchendon, Mass. A more costly affair for larger mincing and chopping operations is made by the "Athol Machine Co." Athol, Mass. "Davis' Patent three minute Cake Mixer" is advertised as "the last sensation." For confectioners, hotels, and large families, it would be very valuable. It is sold by J. H. Rowland & Co., No. 192, State St., New Haven, Ct., and costs from $3 to $5, according to size. The "Common Sense Nutmeg Grater" prevents rasped fingers and waste of nutmegs. It may be had of T. Smith, Jr., 63 Union St., Boston. "Russel's Patent Fruit Seeder" takes the stones out of cherries and the seed out of grapes instanter. Made by Dow & Sprague, Birmingham, Ct., price $1.50. A new peach paring machine, which will pare potatoes to a charm, is shown by D. H. Whittemore, Worcester, Mass., price $10 per dozen. "Jeffrey's Reversible Griddle" is a very ingenious contrivance for turning batter cakes to a dead certainty "as you like it." Address E. A. Jeffrey, Trappe, Talbot Co., Md. Leaving the kitchen and going out of doors, we would call the attention of quarrymen and stone-masons to the "Little Giant Stone Drilling Machine," which drills away at granite very much as a wood-boring machine would do at an oak log. It is to be had of Herrmango & Ostrander, Schuylerville, Saratoga Co., N. Y. Blacksmiths would do well to examine "Stephens' Parallel Vice," sold by Messrs. Stephens 91 Liberty St., New York.

In closing this detail, we may add that there is no show of grain, seeds, roots or vegetables; the display of fruit is meagre; the exhibition of flowers no way remarkable; there are no bee-men lecturing on hives and bee-charms; and no dairy products are to be seen. An address by Dr. Loring, President of the Society, and two evening discussions, one on the "Breeding of Cattle," and the other on "Farming as a Business," were interesting and instructive, but we must not attempt even the briefest synopsis of them.

Stray Notes of Travel in the United States.

[EDITORIAL CORRESPONDENCE.]

New York, Sept. 8, 1868.

Our former communication closed with some account of that rural glory of New York, Central Park, and as the subject was by no means exhausted, it may not be amiss to resume it, so far at least as to make a few remarks on parks and avennes in general. It is said that a Park-making *furore* prevails all over this country at this time. 'Tis well. Worse *furores* might prevail. May this one cross the lines and have a powerful run in Canada! It is much needed. Our towns and cities might have rare sylvan beauty very easily, if our people would only take some little trouble in the matter. The chief feature in parks and avenues is trees, and this can readily be secured. If every owner of a village, town, or city lot would but plant trees in front of his property, how soon would there be "beauty all around." Brooklyn is vieing with New York in park-making. Prospect Park in Brooklyn tries to rival Central Park in New York; but while very beautiful, and scarcely less extensive, it lacks some natural advantages possessed by Central Park. But Brooklyn certainly beats New York in the matter of avenues. New York has nothing that approaches Clinton Avenue in Brooklyn. It is a gem of rural beauty; broad, with spacious flag-stone walks; wide, well-kept grass borders; and rows of magnificent trees. On either side, well back from the front fence, are palatial mansions, with flower gardens, conservatories, and shrubberies about them. Here dwell merchant princes and millionaires, but the poorest individual in the city can walk beneath these majestic trees, and feast on all this floral and herbaceous loveliness. At the present time, a flowering shrub, almost attaining tree proportions, and commonly known as the "Rose of Sharon," is in full bloom, and very beautiful it is. The flowers are large, bell-shaped, and of various colours, not unlike the hollyhock, and like it both single and double. There is also a magnificent white lily, with large, long trumpet-shaped flowers, in full bloom, which is a very showy, attractive object in these gardens. Creepers are largely grown, tropœolums and the cypress vine seeming to be favourites. Ivy may be seen creeping up some of the buildings, as though it wintered out of doors here. No doubt the near vicinage of the ocean modifies the climate considerably, and enables things to be grown which cannot be cultivated out of doors on the same parallel of latitude inland.

Large numbers of goats are kept in the suburbs of New York and Brooklyn, mainly for their milk, though they are driven in children's carriages, making a very pretty appearance, while not a few, owned by the poor, draw carts laden with swill and offal. It is said that an enterprising individual is going to start a "goat livery" close to Central Park, and hire out goat carriages for children to take drives in. We are satisfied, after experimenting for three years with them, that goats are well worthy of being kept for milking purposes. If goats of good milch stock are obtained, their yield of milk is by no means inconsiderable in quantity, while its quality is so rich that it may be diluted one-third with water, and still be equal to cow's milk. For invalids and delicate children, goats' milk is invaluable, as it possesses some peculiarly nutritious quality, desiderated by such as are low in vitality.

The office of the *American Agriculturist*, now removed to larger quarters on the opposite side of the City Hall Park to that on which it used to be located, is well worth visiting. The premises are very extensive, and divided into departmental offices. Besides the business of the paper, the circulation of which is something fabulous, a large trade is done here in agricultural and horticultural publications. Messrs. Orange, Judd, & Co., the proprietors of the *Agriculturist*, publish largely themselves this class of books, and also keep in stock the issues of other houses in the same line. So many works of this description are now extant, that an extensive and costly farmer's library can readily be made up of them. The second story of the *Agriculturist* building is occupied by Messrs. Whitlock & Co., as a general Horticultural Agency. Here a free fruit and flower show is constantly going on, and every Thursday afternoon a horticultural meeting is held for the discussion of questions interesting to professional and amateur gardeners. The discussion is preceded by the reading of a paper on some subject previously chosen. We attended one of these discussions. A paper on "The Profits of Fruit-growing" was read by Mr. A. S. Fuller, author of a little work on "Small Fruit Culture." A well sustained discussion followed. Fruit culture seems to be one of the topics of the day here. Many persons have gone into what is called fruit-farming, and find it pay well. There is almost unlimited market here for fruit. The more fruit is raised, the more the demand increases. In our former communication we spoke of Bartlett pears bringing ten cents each. We have since seen them sell at twice that price; and at the discussion above referred to, it was incidentally mentioned that any quantity can be sold in Boston at twenty-five cents apiece. No such prices could be got in Toronto or Montreal. Canadians are a beef-eating, and Americans a fruit-eating people. Market gardening and fruit-growing are by no means money-making businesses in Canada. The reverse is true here. In the vicinity of all the larger American cities, there are numbers of people who are getting rich by raising vegetables and fruit for the markets.

An enterprising company, the head of which is Mr. S. N. Pike, proprietor of "Pike's Opera House" in this city, have undertaken the reclamation of extensive flats just across the North River from New York, and in the adjacent State of New Jersey. These flats comprising several thousand acres, have been hitherto wet and marshy, yielding only a very coarse description of hay, and therefore, were considered of very little value. The tract has been purchased by the "Iron Dyke Company," as it is termed, at a very low figure. It is being protected from the river by a levee or dyke, which consists partly of dirt, and partly of a continuous plate of iron. This contrivance prevents leaks in the dyke being occasioned by the operations of moles, muskrats, &c., and affords great support to the mound of earth. The dyking is to keep out the tide water; the ordinary height of the river is below the level of the land. When the dyking is finished, it is intended to dry the land by cutting ditches, guarded at the outlets by sluices which can be shut at high tide and opened at low tide. A portion of the tract is already finished, and has been cultivated the present season, and it is expected that there will be 1000 acres ready for tillage by next spring. It is the intention of the proprietors to lease this land,—which they can do at $100 an acre. The soil proves very rich, and well adapted to gardening purposes, to which it is expected the whole area will be devoted when it is ready for use. The cost of these improvements will not bring the outlay on the land higher than $150 or $200 an acre, and already the company has been offered $500 per acre for portions of it. This is what Americans call a "big thing." It is so in more senses than one. It will add considerably to the market-gardening capabilities of the region adjacent to this great city, promote the healthfulness of the city and environs, lessen the number of mosquitoes, which are very numerous and savage, as we know to our sorrow, and bring a golden stream of wealth to the coffers of the fortunate individuals concerned in the enterprise. Moreover, it will lead to similar undertakings in the vicinage of other large cities, and will bestow on them like benefits.

We spent an entire afternoon in that most beautiful city of the dead, "Greenwood Cemetery." To do this noted spot anything like justice, we must devote a whole article to it some time. At present we find it necessary, much against our will, to dismiss it with a paragraph. Nature and art have united here to ameliorate the repulsiveness of death and the grave with wonderful success. It is difficult to realize that it is a burial place, for you feel continually that you are in a lovely park crowded with statuary. The ground is full of natural undulations, which have been turned to the best account by skilful landscape gardening, and so there are hills and vales, mounds, nooks, dells and sequestered places, with carriage-drives and foot-paths gracefully winding in all directions. Every spot partitioned by roads or walks is named, as are all the avenues, alleys, and paths, each having its designation very neatly shown on a small guide board, supported on an iron pedestal or stand. Deciduous and evergreen trees in every style of leafy beauty adorn these grounds, and make them far more a scene of life than of death. Many of the monuments are exquisitely chaste and elegant. Massachussetts and Aberdeen granite marvellously polished, marble of every description, and stones in such variety as might puzzle a geologist, are here, built into mausoleums, sculptured into stone pictures of the dead, read in lofty columns, or employed as humble and simple memorial tablets. Several might be enumerated were we giving a detailed account of Greenwood; suffice it to say that, of all we saw, nothing so thoroughly pleased us as a costly yet simple structure in white marble, recently erected by James Gordon Bennet, of the *New York Herald*. It stands beside three child graves, and the subject is a mother in modern attire, the sculpture showing the silk finish of her dress and the very figuring on her lace shawl, lingering at the spot, and looking cheerfully upward as three cherub forms ascend heavenward. The entire conception and execution form a master-piece for a Christian burial place.

The main entrance to Greenwood Cemetery consists of a very noble gateway, embracing a series of arches, having over them, in bas relief, Scripture scenes, such as the "Raising of Lazarus," &c. As you ascend the hill from the main entrance you have a fine view of the river, shipping, New York, &c., and farther on in the grounds you get very beautiful glimpses of these objects. In one place, called "Ocean Hill," you behold in the distance a very charming sea-view.

Much too hurriedly we must make a brief note of a visit to the farm of Rev. Henry Ward Beecher, at Peekskill, N. Y. We spent an afternoon there very pleasantly in the society of the gifted proprietor and his interesting family. Mr. Beecher's farm consists of thirty-six acres, having a narrow frontage, and sloping up a considerable distance from the stretch of table land below, so that it commands a fine panoramic view of the picturesque region about Peekskill, and takes into the scenery a beautiful sweep of the Hudson river. The buildings consist of the original farm house, somewhat improved since it came into Mr. Beecher's possession, and forming a comfortable but unpretentious family residence, and a large, handsome barn, roofed with variegated slates, and evincing the taste at once of the architect and owner. Mr. Beecher cultivates his domain in the meantime as a vegetable and fruit farm, and it reflects no small credit on his management that last year the sales off it amounted to $3,600. An average of $100 per acre. *Per contra* must be reckoned the wages of seven men during the working season, outlay for manure, team expenses, &c. Mr. Beecher is a better and more practical farmer than we expected to find him. He understands the theory and principles of agriculture thoroughly, and is making intelligent application of them on his little estate, which he is managing not so much for the sake of present profit, as with an eye to making a pleasant home when he retires from active ministerial duties. Most of his land has been thoroughly stirred to the depth of fifteen inches. It is thoroughly enriched with barnyard and artificial manures. Apple, pear, plum, and peach orchards are planted, and a large vineyard set out. These are protected by evergreen screens and hedges, or rather will be when the young trees become large enough. Shade and ornamental trees are growing up to adorn a spot which already possesses extraordinary attractions, and will be a delightful place when the owner's plans are carried out. Mr. Beecher has large plantations of strawberries, raspberries and blackberries; grows early potatoes, lima beans, melons, "ruta bagas," and sweet corn extensively, and has not only a bright and beautiful array of flower-beds close to his house, but seems to grow them promiscuously all over his farm. A good-sized patch of "ruta bagas" (or Swede turnips, as we should call them,) is fringed with three rows of dwarf asters which are just coming into profuse bloom. Mr. Beecher is passionately fond of flowers, and likes to have them wherever he is, even in the pulpit. We were glad to learn from him that his example of high farming is doing his neighbours good, and that a perceptible improvement has taken place, since his advent, in the style of husbandry about Peekskill. Such will always be the effect of growing uniformly good crops through the combined application of liberal manure and skilled labour.

Distress in Red River.

In consequence of the ravages of grasshoppers, the North-west Territory of Red River is almost destitute of crops, and serious apprehensions are entertained in regard to the food supply for the coming winter. The *Nor' Wester* contains an appeal for help to friends in England, Canada, and the United States. We feel assured that this call upon the sympathy and benevolence of those who have during the present year received in such large measure the bounty of Providence will not be made in vain. Meetings have already been held in Toronto, Hamilton, and other cities of this Province, to take the subject into consideration, and active measures are being taken to raise funds to relieve as promptly as possible the wants of the sufferers by this great calamity. In former years the abundance of buffaloes in the territory has mitigated the effects of any scarcity in the crops; but in consequence of the dispersion of these wild herds, resulting from the increasing occupation and settlement of the land, this source of relief is now cut off. We heartily commend the case of our fellow-countrymen to the good feeling and liberality of the farmers of Canada.

Literary Notices.

The American Entomologist.

Edited by Messrs. Benj. D. Walsh, Rock Island, Ill., and C. V. Riley, St. Louis, Mo.; published monthly by R. P. Studley & Co., No. 104 Olive Street, St. Louis, Mo. No. I, September, 1868. Price, $1 per annum.

We gladly welcome the revival, in another form, of that most useful periodical, the *Practical Entomologist*, whose untimely demise we lamented not long ago. The present undertaking, though similar in its objects, is now being carried on under the auspices of no society, but entirely as a business enterprise, by business men, and upon a business footing. With two such men for editors as the State Entomologists of Illinois and Missouri, who have been well known to the scientific world for their writings and investigations, and to the agricultural world for their practical work, the one in the periodical above mentioned, the other in the *Prairie Farmer*, we do not doubt that the proprietors will find their enterprise a successful one, while the farmers and gardeners of the continent will glean from its pages information that will save their pockets, collectively, many thousands of dollars per annum. The first number, which is now before us, consists of twenty large octavo double-column pages, well and clearly printed, and illustrated with nine wood-cuts from the pencil of the junior editor. All the numbers are to be well illustrated, and it is the intention of the publishers to furnish at least one coloured lithographic plate in addition with each volume. The contents of the present number are varied and interesting, and written in an easy and lively style; the first article, which is of an introductory character, proves most conclusively the need of such a journal, and the importance to all of the practical study of the nature and habits of insects. The following sentences, which, considering the devastation of such a wide extent of western country by locusts this year, (witness the appeal for aid from the Red River Settlement.) we do not believe to be exaggerated, are sufficient of themselves to prove this:—"We are certainly speaking within bounds when we assert that, taking one year with another, the United States suffer from the depredations of noxious insects, to the amount of THREE HUNDRED MILLIONS OF DOLLARS. We by no means maintain that it is possible by preventive measures to save the nation the whole of this gigantic sum; but we do contend and firmly believe that it is perfectly practicable, by long-continued observation and careful experiment, to save a considerable percentage of this enormous sum total. It may, and probably will, take many, many years of hard work in the field, and anxious deliberation in the closet, to arrive at such a result; but in the meantime every step that is gained in advance will be so much money saved to the community. Suppose, for example, that during the next two or three years preventive measures should be discovered by which the total annual damage inflicted by insects is diminished only to the amount of one-half of one per cent. Then, according to the data above given, the nation will gain annually, for all time, to the amount of ONE MILLION AND A HALF DOLLARS!"

We are requested to state that, as before, in the case of the *Practical Entomologist*, persons in Canada desirous of obtaining the *American Entomologist* can procure it, postage free, on remitting one dollar to the Rev. C. J. S. Bethune, Secretary to the Entomological Society of Canada; the difference in exchange pays both the American and Canadian postage.

INDIAN CORN—Its value, culture, and uses, by Edward Enfield, published by Appleton & Co., New York.—This is a complete and highly practical treatise on the culture of Indian corn. This important grain is not grown in Canada to the extent to which we believe it might be with advantage and profit. The soil and climate in certain sections of the country are well adapted for this noble cereal, and we hope to see it more extensively cultivated by Canadian farmers. We commend the above work to their attention. The subject is treated concisely, yet very fully, the following being the principal topics successfully treated: Varieties; adaptation of varieties to soil and climate; average yield and productiveness; selection and preparation of seed; planting, after cultivation, harvesting, and storing; enemies and diseases; stalks and leaves as fodder; and finally, its various uses and economical value. The agents for the sale of the work in Canada are Messrs. Adam, Stevenson & Co., Toronto.

THE COUNTRY GENTLEMAN'S MAGAZINE.—We have received, from England, the first number of this new monthly periodical. It is a handsome magazine, octavo size, beautifully printed, with clear and large type, and containing 180 pages of valuable and interesting matter. With this is incorporated the *Journal of Agriculture*, an old established magazine of the highest standing. Most of the articles are reprints from the *Farmer*, (Scottish), a very convenient way of preserving in suitable form the most important and permanently useful matter of that foremost in the rank of British Agricultural journals. The letter-press is illustrated with well-executed engravings, and the whole would form, at the end of the year, a goodly volume of agricultural literature.

WHITLOCK'S HORTICULTURAL RECORDER.—The August number (No. 2, vol. 2) of this publication is full of valuable information on horticultural matters. There is appended a prospectus and catalogue of the "Perpetual Exhibition, or Agricultural Bazaar," referred to in our Editorial notice of the establishment of the *American Agriculturist*.

ELLWANGER AND BARRY'S DESCRIPTIVE CATALOGUE OF FRUIT.—This catalogue, just received from the proprietors of the Mount Hope Nurseries, Rochester, New York, contains, as usual, a very full list of fruits adapted for the United States, and most of them are well suited for our Canadian climate.

O'KEEFE & SON'S CATALOGUE.—We have also received from M. O'Keefe & Son, of Rochester, a Catalogue of Fruit Plants and of Dutch Bulbous Flower Roots—complete and excellent lists.

Agricultural Intelligence.

Agriculture in Scotland.

HILL FARMING—BALMORAL—TREE PLANTING—TURNIP CULTURE—LOWLAND FARMS, &C.

To the Editor of THE CANADA FARMER:

SIR,—I wrote you last from Aberdeen, immediately after the exhibition; since then I have enjoyed the opportunity of seeing a large portion of Scotland, and of having much personal intercourse with farmers and others engaged in the various industrial pursuits of life. I have attended several markets, fairs and local shows, affording me the means of much valuable information, and also of imparting information respecting the resources, &c., of Canada, in which I found great interest manifested in several localities.

"Hill-farming," as it is termed in the more mountainous districts of Scotland, presents many points of interest to a lowlander or stranger. The extent of such farms is often estimated by the amount of cattle and sheep they will maintain, and not by the number of acres they contain. In some parts of the Highlands it requires two or three acres to keep a sheep all the year round, and it is surprising to find how large an area one shepherd, assisted by his wonderfully sagacious dog, can manage to superintend. These dogs, which are generally well trained, are indispensable among these hills and rugged precipices in the management of sheep, and are in fact of much greater service for such purposes than men. In fine weather sheep-farming in the Highlands is a very pleasant and healthy occupation, but like most other pursuits it has its dark side; the rain and snow storms common to these regions at certain seasons, render the shepherd life one of much anxiety, and sometimes even of privation and hardship. In extreme cold and boisterous weather the sheep are collected in the lower grounds, and temporary protection afforded them, and, perhaps, a little hay, turnips, &c., given them; but as a general rule, they have to forage for themselves all the year round, and, with proper attention, it is surprising how well they do. The black-faced or heather sheep is the breed that universally prevails through all the higher districts. They are beautiful-looking animals, horned, the males most gracefully so, extremely hardy, slow growers, and yield the best mutton in the world. They subsist on the coarse grasses and heather of the hills, and the flavor of their flesh is peculiarly savoury, with an exquisitely short and tender fibre, when kept for a few days. I more than once partook of mutton from four years old wethers, by far the finest I ever tasted in my life; much superior to the Southdown, and even to the Welsh mountain breeds. This high degree of excellence, I was informed, could only be attained in animals fully matured by age; a rule that obtains in other of the domestic animals besides mountain sheep. The West Highland cattle are beautiful little creatures, and their beef is of very superior quality, fetching, with the mutton, a higher price to the extent of a penny or more a pound than the larger and coarser breeds, in the London and other English markets.

In the Western Highlands, where the climate is excessively humid, and sheep suffer more from wet than cold, the practice of surface draining the slopes of the hills has been introduced with very salutary results. Small furrows are made by the plough or spade, according to the inclination of the undulating surface, so as to give the water that falls in showers a more ready exit into the lower or natural channels of drainage. This is found to render the surface drier and warmer, to induce the growth of grass of a better quality, and prevent, or at all events mitigate the foot rot. It is a common practice to set fire to the heather when it gets old and scrubby, thus inducing a new growth, which is much coveted by sheep. In some of the lower slopes I learnt that the application of quick lime had been found most beneficial to the natural pastures, sweetening and improving the herbage, both as to quantity and quality, in a high degree.

Your readers will form an idea of the extremely small area capable of cultivation in some parts of the Highlands, when I state, that on Her Majesty's estate of Balmoral, consisting of upwards of 20,000 acres, I was informed that scarcely 500 admitted of any kind of cultivation. Besides the rather extensive ornamental plantations immediately around the castle and the adjoining permanent pasture, I observed only a few acres of oats and turnips, both of which were suffering much from the effects of drought on a thin gravelly soil. The dairy consists of eighteen cows, of the Ayrshire breed, which I did not see, as they were in the woods, for want of grass in the pastures. The dairywoman, as well as her husband, was very intelligent, and quite disposed to afford me any information. The dairy is a small, but very suitable building, rather elegantly fitted up, but all its parts quite in keeping with the object it has to serve. There is no kitchen or fruit garden of any consequence at Balmoral, the soil and climate being naturally unsuited to such purposes.

In these higher districts only a little rye, oats, and barley are grown, and even these crops are in some seasons quite uncertain. Wheat is never attempted. Potatoes and turnips do pretty well. Hay is the most important crop, and is produced of pretty fair quality in the narrow valleys. As an instance of the peculiar character of the present season, I may observe that I saw oats and barley nearly ready to cut in the middle of August, full six weeks before the ordinary time. Indeed there are in most years portions of grain crops standing in the more exposed situations, after snow has commenced falling. One farmer told me he did not harvest his small quantity of grain in good condition more than one year in four, and that he looked more to the straw than to the grain.

Having heard and read much about the planting of the Highlands with fir, larch, &c., with a view to shelter and profit, I must confess to a feeling of disappointment on the first view. The trees on the higher elevations presented a scrubby and unthrifty appearance, but in lower situations, where the soil is better and shelter obtained, the conditions are more favourable, and in most localities artificial planting can be, no doubt, carried on with success and profit. The planting of wood very much enriches the landscape, and improves the climate, rendering the country more comfortable and salubrious for both man and beast. On the extensive estates of the Duke of Athol many thousands of acres were planted with the larch fir principally, more than half a century ago. Many of these woods appear to be in a thriving condition, and large quantities of excellent timber have already been taken from them; while there are others I thought in an almost non-progressive state. I was told that of late years a worm had been doing considerable mischief, and that several acres of trees, in some places, had actually died. No antidote has yet been discovered.

Scotland presents most remarkable illustrations of the connection between the physical conformation of a country and the industrial pursuits of its people. The Highlands proper, are by soil and climate for ever destined to the pasturage of hardy sheep and cattle, and can only support but a very sparse population; while the lower and richer grounds of the South, including portions of the East, abounding in some localities with coal and iron, afford the means of ample support to large numbers of people busily engaged in the various industrial pursuits of agriculture, manufactures and commerce. In travelling over the country one is struck with the ever varying face of nature, and is forcibly reminded how much the composition and productions of the soil, and the nature of the pursuits of the people in the present day, are the results of physical forces operating on the crust of the earth through long ages of the mysterious past.

I had the pleasure of spending two or three days in the County of Fife, principally with Mr. Robert Russell and friends, near Leven. Mr. Russell, some years ago, spent several months in the United States and Canada, and published the best book for practical purposes ever written, perhaps, on America. I had a beautiful drive through a portion of the eastern section of the county along the coast, where there are some excellent specimens of farming. The soil is generally good, in some places very rich, fetching high rents,—say from £2 10s, to £4 per acre. Most of the grain was cut, and the yield of wheat estimated at from forty to sixty-five bushels an imperial acre. Spring grain was, in consequence of the drought, under an average, the same of root crops, though I found turnips in Scotland much better than in England, particularly the south, where they are generally all but an absolute failure. The present season affords a very useful lesson in regard to turnip culture; clearly demonstrating that the *mechanical* condition of the soil is of the utmost importance. Much of the arable land of Scotland is warm and friable, formed by the disintegration of the primitive rocks, and, with the climate, naturally adapted to turnip culture. But even here turnips appeared patchy in fields where the texture of the soil, and consequently the cultivation, was not uniform; while upon the heavier soils of many parts of England a sufficiently fine and deep tilth could not be obtained, and the consequence was that during the severe drought the seed never germinated. The showers that have recently fallen have, however, caused germination to commence,—but too late to produce a crop. On soils that are friable and well worked, a fair crop of Swedes will probably be produced. Farmers who fail to grow turnips on unsuitable or badly prepared soils, are apt to attribute the result to bad seed, rather than to their own neglect or want of judgment. Mangel-wurtzel is but little cultivated in Scotland, the average heat of the growing season not being generally high enough to develop sufficiently its saccharine quality.

I felt greatly disappointed in not finding Mr. George Hope, of Fenton Barns, at home, having anticipated much pleasure in some personal intercourse with so distinguished an agriculturist. I went over the farm, however, with his reeve, Mr. Bertram, a thorough agriculturist of the practical school, who was disposed to give readily any information required. Mr. Bertram has three sons settled in Ontario, and has visited the Province himself, and thinks highly of its condition and capabilities. Mr. Hope farms about 1,000 acres, and no one can give even a cursory glance, without being convinced that the operations of this fine and extensive farm are conducted on the most approved principles of improved husbandry. The soil is among the best in East Lothian, a district renowned for its great productiveness. The farm has been in the same family for two or three generations, and very important permanent improvements have been made, from time to time, by way of draining, straightening fences, &c. A steam plough with cultivating apparatus has been introduced with the most satisfactory results, diminishing horse-power more than fifty per cent., and ensuring an early and well prepared seed-bed. The wheat crop was very heavy, all cut and ready for stacking, but the recent heavy rains had retarded progress,—sprouting even had actually in some places commenced. The period was critical, and farmers were looking to the immediate future with considerable anxiety. Mr. Hope keeps a first-rate Shorthorn bull, which serves selected cows, in most of which the same blood predominates, producing stock of rapid growth and large size, profitably adapted to the butcher. There are on the farm some excellent pure bred Leicester sheep; but half-breeds, that is, a crop between the Leicester, Cheviot, Lincoln, or some other sort, predominate in this and other districts of the Lowlands. In travelling through this fine section of country one is struck with the novel appearance of a tall chimney in almost every farm steading, the motive power in threshing, cutting straw, &c., being generally steam. Mowing and reaping are principally done by machines, as is now the case in many parts of England. Samuelson's reapers, with self-raking and delivery apparatus, appear to be the most generally used. Some of your readers may not be aware that the original inventor of the reaping machine is a Scotch clergyman, still living; but Mr. Bell's machine, which is propelled by horses from behind, though it does excellent work, is of heavy draught and but little used. The members of the Highland Society, and others, recently presented Mr. Bell with a testimonial, consisting of one thousand pounds, as a mark of respect for his character and the great worth of his invention. I believe this gentleman resided in Canada for a while, many years ago, as tutor in the family of the late Hon. Adam Fergusson, of Woodhill.

In looking back on the history of British agriculture in the present century, there can be no doubt that the formation of the Highland Society was an important starting point in the process of the art; and that the exhibitions and proceedings of that, which may in strict truth be termed the *parent* society, have exercised a most beneficial influence on British agriculture, and that of the numerous colonies and settlements in connection with the mother country. I left Scotland with regret, my time being far too limited, and with a deep sense of the intelligence and character of the people.

As one travels from north to south, even if it be but three or four hundred miles, a marked difference obtains in the time of performing the more important operations of the farm. When I left Scotland the farmers were in the midst of harvest—very little had been secured; but on reaching the great central plain of Yorkshire, only here and there a late sown field had the grain uncut, and in the south and south-west the crops had been secured for nearly or quite a fortnight, and in capital condition. But little threshing has yet been done, and from all I can learn where that decisive test has been applied, the wheat crop promises to turn out abundant—considerably, I should think, above an average. I have met with a few instances of the threshing not fully coming up to previous expectations; these, however, will probably prove exceptions, not the rule. Spring grain on good soils, with a fine, deep tilth, will afford a fair yield; but all late sowings with indifferent culture, cases by no means rare, will be very deficient, or an absolute failure. The recent rains have already produced a marked change in the appearance of the pastures, which only a few days since were as brown and bare as a turnpike road; they are now assuming a beautiful green—grass is beginning to grow, and farmers have a prospect of abundance of keep through the autumn. This will have a desirable effect on the price of sheep and cattle, which of late have been much depressed in value. I hear but an indifferent account of the state of the hop plantations, many of which have rapidly gone off during the past few weeks; but as I expect to be in the south in the course of a few days, I will defer further remarks till I have had the opportunity of personal observation.

GEO. BUCKLAND.

Peterborough, August 26, 1868.

FALL SHOWS.—The Fall Show of the East Elgin Agricultural Society will be held at St. Thomas, on Tuesday, the 6th of October.

☞ A joint Show of the West Riding of York and Township of Vaughan Agricultural Societies will be held at Burswick, on the 20th and 21st of October. As an inducement to the sons of farmers, they offer $12 for the first, and $8 for the second-best essay upon "Practical Farming," to be the composition of a resident of the County, practically engaged in agriculture, and under twenty-one years of age; the essays to be forwarded to the Secretary on or before the 15th of October next, the essay to become the property of the Society.

☞ Hay is being exported from Montreal for the English market.

☞ Upwards of 4,000 sheep infected with small-pox, or sheep pox, have been received in England from the continent; in consequence of which, an Order in Council has been passed providing for the inspection and quarantine of all foreign sheep before admitting them into the English market.

WHEAT PREMIUMS.—Messrs. Moore, Foote & Co., of Detroit, have offered the Michigan State Agricultural Society the sum of $400, to be given in premiums, for the best fields of white winter wheat grown in Michigan. The Society have accepted the donation, and announce three prizes, of the sums of $250, $100, and $50 respectively, for the three best fields, consisting of five acres each, of white winter wheat, sown this fall, and harvested in 1869.

BREEDING HORSES IN AUSTRALIA.—Two Australian horses, "Fish Hook" and "Marchioness," were sold during the week ending 23rd of May last, to Mr. Hunter, who buys for the India Market, the price being for the two £1,500 sterling—upwards of $7,000. The services of a favorite horse, "Ace of Clubs," son of "Stockwell," are advertised at twenty sovereigns. A race-horse breeder and turf man, D. L. S. Smith, is just disposing of his farm of one hundred and thirty-six acres, and thirty head of horses, mares, and colts, by lottery, at £5 sterling per share in 1,000 shares.

NEW YORK GRAPE GROWERS' ASSOCIATION.—ANNUAL FAIR.—The first annual exhibition of the New York Grape Grower's Association will take place at Canandaigua on the 7th and 8th of October. The exhibition will comprehend the Grape, its products and the implements which pertain to its culture, gathering, preparation for market, and manufacture into wine or brandy. Grape growers and manufacturers of wines, brandies and implements, from all parts of the Union and the British Provinces, are invited to become exhibitors and competitors. There will be a meeting on the evening of the first day of the Fair, during which the following subjects will be discussed: 1. Soils, and their preparation for planting. 2. Varieties, and their adaptation to soils and localities. 3. Pruning, and the season in which it should be done. 4. Best mode of trellising. 5. Over-cropping, and its consequences. 6. Renovation of worn-out vineyards. 7. Marketing. 8. The benefits of the grape and its products on the health of the people.

The Apiary.

The Koehler Secret Revealed—A New Mode of Propagating Ligurians.

Mr. Koehler has recently made his process public in the following article, which appeared in the *German Bee Journal*:—

Now as to the operation itself. It is founded on my observation, that during many fine forenoons and afternoons the air is still warm enough for queens to fly ont when drones usually have not commenced flying, or have ceased to take wing. Until, therefore, the young queens become fertilised we must compel the Italian queens and drones to go forth at such times as the German drones cannot possibly be abroad. The time during which drones are on the wing seldom extends with us to later than 4 or 5 o'clock P.M. If, therefore, we have one or more colonies, with young queens which we know to a certainty have not yet been fertilised, we place these hives for three, four, or five days in a perfectly dark and cool cellar, and with them also the stock which contains the Italian drones. Whenever a very warm and sunny day occurs, we watch the German stocks until the drones have ceased their flight. As soon as this occurs we restore the hives containing the Italian queens and drones to their accustomed stands, and set them at liberty after giving to each a copful of their liquid honey. The queen and drones being ardent, and having been unable to fly for days, the bees excited by the honey and their previous confinement, become so eager after flight, that all play as if mad, and fertilisation follows. We must, however, be careful to return to the cellar in the evening every colony the queen of which has not been seen to return with the sign of fertilisation, and repeat the process until it is certain that the desired result has been attained. This is essential, because it is well known that under ordinary circumstances some queens take flight several times before they succeed in meeting with a drone. How much more, therefore, must this be the case under the foregoing management, whereby the number of available drones is limited to those only which exist in the few Italian stocks?

But now I will make a second communication, which will certainly also be agreeable to you. I do not know whether you give the preference to natural or to artificial swarms. My practice combines both, as by it I obtain natural swarms by an artificial process, and can at the same time with one good Ligurian stock Italianize a dozen colonies with the least possible trouble. The process is as follows:—We take a hive from which a swarm has just issued, and put it in the place of another very populous colony. After nine days, by means of the population received from the removed hive, it will certainly swarm again. If it is now shifted to the stand of another strong stock, it will, after two or three days, swarm again. We continue this process as long as we can hear queens piping in the hive of an evening. Under favourable circumstances we may in this way obtain ten to twelve swarms, as the first hive supplies the queens and the others the bees. If, therefore, we have one or two Italian stocks, and feed them well early in the spring, say from the 20th of March, especially if they are well supplied with pollen, we may be sure that these hives will swarm first. By transposing them in this way with German stocks we shall obtain swarms with Italian queens and German bees.

The advantages offered by my system are very great. In the first place we secure early swarms with young queens, and these queens are generally larger and better than those which bees hatch by compulsion. How quickly also can we Italianize a hive; for it is only changing places with two hives and the work is done. We can also put the swarms in any place we choose, which is less trouble than with artificial swarms, which we cannot always establish where we would wish to have them. We know also the day and the hour in which to expect a swarm, for the second appears in nine days after the first removal, the third three days after this, the fourth on the next day, and so on. If we still hear queens piping after the last removal, the stock will swarm to-morrow, and if we convey it into a dark cool cellar in the evening, we can cause it to swarm at any hour we please by bringing it out into the light and sunshine, and feeding it moderately.

It follows, as a matter of course, that the foregoing method can only be practised with single hives, which can be moved from place to place although they may have fixed combs. Those who have bee-houses can, however, adopt it, because they can transfer their hives from one place to another.

I have still to add one remark:—The process for securing pure fertilisation can only be relied on early in the season, and not towards the end, for it often happens that certain stocks which have hatched young queens will, as soon as they are fertilised, begin to expel their drones, as I have observed to be the case this year. In such instances the drones do not cease flying so punctually as usual, but often continue on the wing from early in the morning until quite late in the day. We must not, therefore, be too late in breeding Italian queens, and liberal and judicious feeding is and will be the surest means of expediting it.

In the hope that you will be enabled to make experiments, the results of which may not be marred by any unforeseen accident, and desiring that you may be satisfied by experience of the value of my method, I am, &c., Koehler.

Bees.—One of our correspondents in this city sends us the following:—The deficiency of flowers in Toronto gardens has driven the bees to the sugar factories. At Hessin's Sugar Bakery, on King street, these industrious insects may be seen as thick as flies are ordinarily in such situations. They go in and out of the workshop, and no doubt appropriate every morsel they can get at. Immense numbers are killed, but it does not seem to thin the comers. Query.—Do bees, when fed on sugar, produce honey? If so, in what proportion?

The Household.

Bad News for the Rats

Recent experiments show that squills (*Scylla maritima*), the enormous bulbous root of which is much used in medicine, is not only a powerful poison for rodents, but also one they are very fond of. The way of preparing it for the desired purpose is as follows: One of the bulbs is cut into slices, hashed and bruised, then done in the can with fat, which is afterwards strained through a cloth and poured into broken plates and saucers, to be placed in the cellars and other places infested with rats, mice, &c. To prevent dogs and poultry from eating of this poisonous compound in stables, pigeon-houses, or farmyards, it may be put into a wooden box, about a foot and a half long, and having a hole at each end. The rat gets in at one end and goes out at the other, after partaking of the noxious food, which soon kills it. Squills may also be reduced to powder for the same purpose, by bruising them in a mortar to a pulp, which is afterwards incorporated with as much flour as it will hold. This paste is then rolled out, as they do for a pudding, then cut into shreds, which are left to dry on hurdles or on sheets of pasteboard, and are afterwards pounded in a mortar. The powder thus obtained will keep for years, and may be put into boxes or barrels. If manufactured on a large scale, it may become a profitable article of exportation. In Algeria squills cost nothing, the country being absolutely overrun with them.—*English Paper.*

How to Keep Silk.

Silk articles should not be folded in white paper as the chloride of lime used in bleaching the paper will probably impair the color of the silk. Brown or blue paper is better; the yellowish, smooth, India paper is the best of all. Silk intended for dress should not be kept long in the house before it is made up, as lying in the folds will have a tendency to impair its durability by causing it to cut or split, particularly if the silk has been thickened by gum. Thread lace veils are very easily cut. But dresses of velvet should not be laid by with any weight above them; if the nap of a thin velvet is laid down, it is not possible to raise it up again. Hard silk should never be wrinkled, because the thread is easily broken in the crease, and it can never be rectified. The way to take wrinkles out of silk scarfs and handkerchiefs is to moisten the surface evenly with a sponge and some weak glue, and then pin the silk with some toilet pins on a mattress or feather bed, taking pains to draw out the silk as tight as possible. When dry, the wrinkles will have disappeared. The reason of this is obvious to every person. Some silk articles should be moistened with weak glue or gum water, and the wrinkles ironed out by a hot flat-iron on the wrong side.—*Leisure Hour.*

Herbs.—Every housekeeper, where there is a garden attached to the premises, should have her bed of herbs of all the different varieties used in a family. They are very hardy, and once cultivated they will not soon be given up

☞ "Cheaper than dirt" is the pertinent inscription on a case of soap in an apothecary's window.

☞ When the Hindoo priest is about to baptise an infant, he utters the following beautiful sentiments: "Little baby, thou entorest the world weeping, while all around thee smile. Continue so to live that you may depart in smiles, while all around you weep."

Test Your Kerosene.—In view of the many lamp explosions resulting almost invariably from the use of bad kerosene, we urge upon the heads of families the importance of testing their oil before use in the lamp. This may be readily done by any man, woman or child, by means of a thermometer, a little warm water, and a tablespoonful of oil. Fill the cup with warm water, the temperature of which is to be brought to 110 deg. Fah. Pour the oil on the water; apply flame to the floating oil by match or otherwise. If the oil is unsafe it will take fire, and its use in the lamp is dangerous, *for it is liable to explode.* But if the oil is safe and good it will not take fire. All persons who sell Kerosene that will not stand the fire test at 110 degrees, are liable to prosecution.—*Ex.*

An Imperfect Angel.—One of the younger members of the French Legation at Washington is noted for his gallant and exquisite compliments. One evening, at a "german" at Govenor Morgan's, he was introduced to a witty New York lady who had an ugly flat nose. The polite Frenchman discreetly complimented her on her dancing, to which she archly replied, "Ah! I have heard you are flatterer, but you cannot find it in your heart to compliment me on my personal beauty, so you praise my dancing." "Madam," was the reply, with a Parisian bow, "you are an angel from heaven, but you fell on your nose." —*Exchange.*

Miscellaneous.

The Trial of the Rooks.

At a recent meeting of the "East Lothian Agricultural Club," Mr. Durie, Barneymains, in speaking to a motion, of which he had given notice at last meeting, as to the desirableness of diminishing the number of crows (rooks), said that he was certain that crows did an immense amount of damage to every farmer in the county. Mr. Scott Skirving, and other friends of the crows, said that they killed vermin. No doubt they did; but if they could put the amount of damage against the amount of good they did, the balance would be found to be on the wrong side for the farmer. He did not want their entire extirpation, but simply that they should be kept down, say to about half the number there were at present. He moved a resolution to the effect that the club was of opinion that the number of crows should be diminished, and that the proprietors should be communicated with, in the hope of their taking means to destroy them in their districts.

The Chairman stated that many years ago an application was made to the Earl of Wemyss to allow persons to kill crows in Amisfield Park. His Lordship gave orders that every one should be killed, and 30,000 were supposed to have been destroyed in two days. From that day to this, not a crow had been allowed to build in the Park. He did not think the crows were so plentiful in the county as they once were, but they were still too numerous.

Mr. Mill, Lugate, said he really thought that to a large extent the crows were the farmer's friends. They preserved the crops from grubs, and he thought it would be for their advantage if magpies and hawks were allowed to live, as they were many years ago, for the purpose of keeping down the small birds.

Mr. Elder, Bearford, thought crows kept in a limited number would do good, but not in their present number. He knew that crows were fond of worms and grubs, but he also knew that they liked wheat, especially when coming through the ground. They might sow to the extent of a bushel of wheat less per acre but for the crows. If those who spoke in favour of the crows had visits from as many of them as he had, they would have a different opinion.

Mr. Elliott, Abbey Mains, seconded Mr. Durie's motion.

Mr. Jenkinson, Kidiaw, said that the crows "harried" a great number of the partridges' nests—otherwise, he had never seen them do any harm.

Mr. Smith, Whittingham, said his opinion was not confined to this district—that the crows were very destructive. They took up, for instance, seed potatoes when they were planted. He had known them carry off these potatoes in their bills, and drop them when pursued. Whatever might be the natural food of the rooks, he thought that it was evident that they had a "crap for all corn." Whatever magpies did, it was well known that rooks destroyed eggs to a large extent, so that he did not think it would require much persuasion to get gamekeepers to promote their views.

Mr. Mill said he never in his life saw crows attacking ripe grain; he had seen it many a time, however, destroyed by wood-pigeons. He never in his life saw crows on a stook.

Mr. Belfrage corroborated Mr. Smith's opinion as to the damage inflicted by crows in the potato fields.

The Chairman said a celebrated naturalist had stated that he would be obliged to any gentleman who could tell him that he ever shot a crow and found a grub in it, averring that they did not like the grubs.

Mr. Paton, Standingstane, said that he would much rather have partridges and small birds increased than the continuance of the present number of crows.

Mr. Wyllie, Bolton, stated that the crows in seeking the grubs pulled out the plants. He thought that instead of looking to crows for the destruction of vermin, they should apply the manures which would accomplish that object. He had seen thousands of crows sitting on stooks, and found many of them, which could not be taken in for some days on account of the wet, reduced to mere chaff.

Mr. Durie's resolution was then unanimously agreed to.—*Mark Lane Express.*

Cemetery Advertising

It is well known that at the Père-la-Chaise Cemetery, Paris, there stands in a conspicuous position a splendid monument to Pierre Cabochard, grocer, with a pathetic inscription, which closes thus:—"His inconsolable widow dedicates this monument to his memory, and continues the same business at the old stand, 167, Rue Mouffetard." Now, a Parisian paper relates that a short time ago a gentleman, who had noticed the above inscription, was lead by curiosity to call at the address indicated. Having expressed his desire to see the Widow Cabochard, he was immediately ushered into the presence of a fashionably dressed and full-bearded man, who asked him what was the object of his visit. "I came to see the Widow Cabochard, sir." "Well, sir, here she is." "I beg pardon, but I wish to see the lady in person." "Sir, I am the Widow Cabochard." "I don't exactly understand you. I allude to the relict of the late Pierre Cabochard, whose monument I saw yesterday at the Père-la-Chaise." "I see, I see," was the smiling rejoinder. "Allow me to inform you that Pierre Cabochard is a myth, and therefore never had a wife. The tomb you admired cost me a good deal of money, and, although no one was buried there, it proves a first-rate advertisement, and I have had no cause to regret the expense. Now, sir, what can I sell you in the way of groceries?"—*The Grocer*

An Opening for Emigrants.—Any stout, healthy young fellow, who has no desire to amass money—who has no objection to continual watchfulness and occasional hard work—who does not fear exposure to all sorts of weather—who can be content with mutton and hard biscuits every day all the year round; and lastly, who has no particular love for the society of either man or woman, might be very happy as a shepherd in Buenos Ayres, and will have no difficulty in finding employment.—*Random Sketches of Buenos Ayres.*

Argumentum ad Hominem."—A sceptical young collegian confronted an old Quaker with the statement that he did not believe in the Bible. Said the Quaker:

"Does theo believe in France?"

"Yes, for, though I have not seen it, I have seen others that have: besides, there is plenty of corroborative proof that such a country does exist."

"Then theo will not believe anything theo or others has not seen?"

"No, to be sure I won't."

"Did thee ever see thy own brains?"

"No."

"Ever see anybody that did?"

"No."

"Does theo believe theo has any?"

Quits.—A leading farmer of the parish having refused to pay, the churchwardens resolved to make an example of him. A summons was therefore taken out against the farmer, and in due course a warrant of distress was lodged in the hands of the officers, from whom he was informed he might expect a visit in a day or two. Our farmer accordingly took the precaution of removing from his yard all the stock which it would be inconvenient to have sold under such disadvantageous circumstances. A sow happening to wander into the premises, was, however, suffered to remain, and the bailiffs and police hauled it off in triumph. The animal was presently sold for about one-third of its value, and the churchwarden waited upon the farmer with the trifling surplus that remained after deducting the rate and the costs. "I told you," said he pomposily to the delinquent, "I should be obliged to make an example of you; this is what comes of disobeying the law." "Ah," replied the farmer, "they've sold your old sow, so you'd better keep the balance."

The Colonies of Great Britain.—The colonies of the Empire were established as follows:—Newfoundland, in the year 1536; Malaccas, 1579; Gambia and the African gold coast, 1618; Cape of Good Hope, 1620; Nova Scotia, 1621; Barbadoes, 1624; Nevis, 1628; Bahama Islands, 1630; Antigua, Montserrat and Anguila, 1634; Bengal, 1634; St. Helena, 1659; Jamaica, 1655; Cape Coast Castle, 1661; Bombay, 1662; Tortola, 1666; Dominica, 1668; Belize, 1674; Gibraltar, 1704; New Brunswick, 1713; Prince Edward Island and Cape Broton, 1745; Lower Canada, 1759; Upper Canada, 1760; Grenada and St. Lucia, 1762; Tobago, St. Vincent and Ceylon, 1763; Falkland Islands, 1666; New South Wales, 1770; Sierra Leone, 1787; Vancouver's Island, 1792; Demarara, 1796; Trinidad, 1797; Goze, 1798; Malta, 1800; Port Philip, 1802; Van Dieman's Land, 1803; Heligoland, 1807; the Ionian Isles, 1809; Mauritius, 1810; New Zealand, 1814; Ascension Island, 1815; Natal, 1824; Fernando Po., 1827; Western Australia, 1829; British Guinea, 1831; South Australia, 1834; Victoria (Australia), 1837; Hong Kong, 1849; Labuan, 1848; Lagos, 1851; British Columbia, 1858; Queensland, 1859.

FRUIT AND ORNAMENTAL TREES

FOR FALL OF 1868.

WE have the pleasure of announcing that we are prepared for the Fall Trade with an unusually large and well grown stock, embracing

Standard and Dwarf Fruit Trees.

Grape Vines, new and old sorts, strong open ground plants.
Currants, Raspberries, Blackberries, and all the small fruits.

ORNAMENTAL TREES AND SHRUBS,

Roses and Flowering Plants of every description.

Nurserymen, Dealers, and others, purchasing largely, will be dealt with liberally, and all orders, however small, will receive prompt and careful attention. Parties interested will do well to consult the following Catalogues, which are just issued, and will be sent pre-paid on the receipt of 10 cents. each, for Nos. 1 and 2, and 5c. for No. 3.

☞ No. 1, Descriptive and Illustrated Catalogue of Fruits. No. 2, Descriptive and Illustrated Catalogue of Ornamental Trees, &c. No. 3, Descriptive Green House Plants. No. 4, Wholesale Catalogue, FREE.

AYRSHIRE BULL FOR SALE.

THE Subscriber will offer for sale at the approaching Provincial Exhibition, to be held in Montreal, A **PURE BRED AYRSHIRE BULL,** 17 months old, from his imported cow "Effie," by the County of Beauharnois Agricultural Society's imported Bull "Marquis."

J. M. GROWNING,
Beauharnois, P.Q

18th August, 1868. v5-17-3t.

MILLER'S

INFALLIBLE

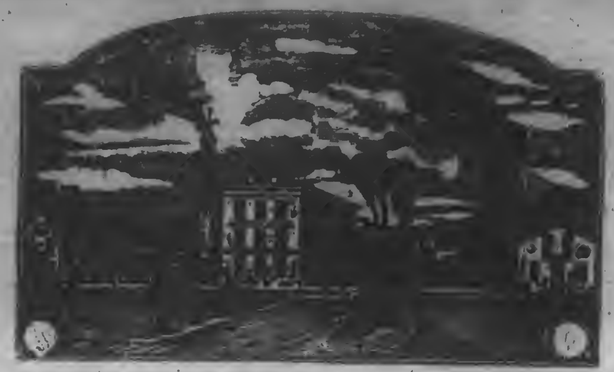
TICK DESTROYER FOR SHEEP!

DESTROYS the TICKS; cleanses the skin; strengthens and promotes the growth of the wool, and improves the condition of the animal.

It is put up in boxes at 35c., 70c., and $1, with full directions on each package. A 35c. box will clean twenty sheep.

HUGH MILLER & Co.,
187 King Street East. Medical Hall, Toronto.

v4-14-tf



WE are turning out from five to ten Threshing Machines per day, and can fill orders PROMPTLY. Our machines are not equalled in Canada, nor excelled in the United States. We now furnish the Burwick or Abel Gear without extra charge, and hereby guarantee those purchasing it from us against all loss or damages for infringement of patent claimed for it by Mr. John Abel. Address

F. W. GLEN,
EXECUTOR, OSHAWA, ONT.

August 28, 1868. (5 17-tf.)

IMPORTANT
AUCTION SALE
OF PURE-BRED
SHORT-HORNED CATTLE
AND
LEICESTER SHEEP.

THE Subscriber has received instructions from Mr. Wm. Douglas to offer for Sale by Auction, at his farm, **Lot No. 80, Township of Onondaga**, four miles West of the Caledonia Station of the B. & L. H. R., on **Thursday**, the **15th Oct., 1868**, the following valuable stock:

Three Cows in Calf; two Heifers, two years old, do.; three Heifer Calves; five Bull Calves; one Grade Cow; one Grade Heifer, two years old; twelve pair Shearling Leicester Ewes; eight pair Ewe Lambs; six Rams, and eight Ram Lambs. Full Pedigrees of the Durhams will be furnished at sale.

TERMS OF SALE:—Twelve months credit will be given on furnishing approved endorsed notes.

☞ Sale to commence at eleven, a. m.

HENRY PEATMAN,
Auctioneer.

Onondaga, Sept., 1868. v5-18-2t

SHORT-HORNED CATTLE
AND
IMPROVED FARM STOCK.

MR. THORNTON, having lived ten years with Mr. Strafford, editor of "Coates' Herd Book," is prepared to buy and ship SHORT-HORNS, or any kind of pure bred farm stock, supply information regarding them, or execute commissions in the old country.

"The Circular," a record of Short-Horn transactions in England, and list of animals for private sale, published at intervals. Price $6 annually. Post free.

JOHN THORNTON,
15 Laugham Place,
London, England.

v-5-18-7t

IMPORTED BERKSHIRE PIGS,

THOROUGHBRED, and from get of Imported and Provincial first prize animals.

☞ **One Litter for Sale at LOW FIGURES.**

STERLING ALGUIRE'S
MILK AGITATOR,
PATENTED APRIL 15, 1868.

STERLING ALGUIRE PATENTEE,
FARMERSVILLE, ONT.

☞ For particulars address

J. B. HARRIS, ASSIGNEE,
Belleville, Ont.

The attention of factory men is respectfully called to the following testimony from one of the best factories in Oxford County:

NORWICH, ONT., Aug. 26, 1868.

J. B. HARRIS,

DEAR SIR,—Your Agitator needs no recommendation, it will recommend itself, and every cheese manufacturer can become convinced by giving it a fair trial; for my part I would not have it taken out of my two vats for twice the price. No cream can possibly rise, and it cools the milk to the same temperature as the water with one quarter inch stream of water.

Respectfully yours, H. S. LOSEE.

MONTREAL VETERINARY SCHOOL
IN CONNECTION WITH MEDICAL FACULTY OF
McGILL UNIVERSITY,
UNDER THE PATRONAGE OF
THE BOARD OF AGRICULTURE,
PROVINCE OF QUEBEC.
(ESTABLISHED 1866.)

CLASSES.	LECTURERS.
Anatomy of Domestic Animals, Botany	D. McEACHRAN, M.R.C.V.S. PRINCIPAL DAWSON.
Institutes of Medicine (Physiology and Histology,)	PROF. FRASER.
Chemistry (Theoretical and Practical,)	PROF. CRAIK.
Veterinary Medicine and Surgery,	D. McEACHRAN, M.R.C.V.S.

Practical instructions daily. Dissection during the Session. Lectures commence 12th November.

☞ For Particulars apply to

GEO. LECLERC, ESQ.,
SEC. BD. OF AGRICULTURE.
Or to D. McEACHRAN, V.S.,
697 CRAIG ST., MONTREAL.

v5-18-4t.

Markets.

Toronto Markets.

CANADA "FARMER" Office, Sep. 11th, 1868.

THE Produce market since our last report has been quiet and dull. Barley has been offering, but the receipts have been light since the decline in prices. Only a very few loads of wheat have been offering on the street market.

FLOUR—The market is still dull. Holders have been asking $6 for No. 1 super, and buyers have refused to buy at that price. Some lots were offered to day at $6 85 and found buyers at that price; choice brands might bring 5c. more, or $6 90. There are very few buyers, however, at these prices. Extra is selling in broken lots at $7. Superior is nominal, offering at $7 25 without buyers.

Oatmeal—Only a retail demand; selling at from $6 50 to $6 75.

Cornmeal—Selling at from $4 to $4 5c.

Wheat—There are only a few lots in the market. Spring wheat is in fair demand, but prices are weak. There are buyers at $1 25 here. Fall wheat is nominal at $1 30. There are no lots on the market, and it is impossible to give correct quotations. Midge-proof sells at about the same rate as spring. There is, as yet, very little coming in on the street market. Street prices are—Spring and Midge-proof $1 27 @ $1 28; Fall $1 30 @ $1 33, according to quality.

Oats—The market remains unchanged. Holders are asking 51c. for car lots. There are no buyers at over 48c. to 50c—on the street market buyers were paying 51c.

Butter.—Coming in slowly; holders are firm, believing that buyers will have to come to their terms; we quote dairy from 20c. to 22c.; round lots 18c. to 20c.; those packed in small lots sell at 19c.; rolls on the market 25c. to 27c.

Eggs.—Selling on the market at from 11c. to 13c.; shippers are paying 11½c.

Cheese.—Only a retail trade doing; worth from 11c. to 12½c.

Pork.—In few hands; holders are asking $24, with a few small lots selling at $23 75.

Bacon.—Selling in small lots at 11c. to 12½c.; market is very bare.

HAY AND STRAW.

There is not much hay yet coming in. Prices continue to be well maintained. We quote hay at from $11 to $15. Straw is rather low; and ranges from $6 to $8.

Barley.—The recent decline in the United States markets has lowered prices here. The receipts from farmers' teams have in consequence fallen off very materially. On no day this week has there been over 5,000 bushels received on the street market, and the receipts by car have also been greatly diminished; not amounting by half to those of the previous week. The decline has depressed the market; few large lots have been offering, and there has not been much desire to buy. To-day there were buyers of cargo lots at 95c. On the street market prices have ruled steady during the week from 95c. to 97c. There seems to be no likelihood of an immediate advance from these prices, as the tendency of the U. S. market is downward.

Peas.—There has been nothing doing in car lots—prices are nominal at 95c.; on the street market from 95c. to 96c. was paid.

Montreal Markets.—Sept. 11.—*Flour.*—Superior Extra, $7 25 to $7 50; Extra, $6 50 to $7 00; Fancy, $6 25 to $6 50; Welland Canal, Superfine, $5 90 to $5 95; Superfine No. 1 Canada wheat, $5 90 to $6 30; No. 1 Western wheat, $5 90; No. 2. do. $5 60; Fine, $5 20; Middlings, $4 50 to $4 75; Pollards, $3 to $3 50. Bag Flour, $3 to $3 10.

Wheat—Canada Fall, $1 30; Canada Spring $1 30; Western $1 30. *Oats*—Per 32lbs. 45c. to 46c. *Barley*—Per 48lbs. 90c. *Butter*—Dairy 20c. to 21c; store packed 19c. to 21c. *Cheese*—Factory, 10c. to 10½c. per lb.; Dairy 9c. to 10c. *Eggs*—14c. *Ashes*—Pots, $5 75.; Pearls, $5 30c. *Pork*—Mess, $24; thin Mess, $24 50c; Prime Mess, $18 75c.; Prime, $16 25c. *Lard*—10c. to 10½c. *Peas*—$1 10c. to $1 12½c. *Rye Flour*—$4 50c. *Oatmeal*—$5 60. *Cornmeal*—$4 to $4 10.

Milwaukee Markets.—Sept. 11, noon.—Wm. Young & Co.'s report.—Wheat—Receipts, 91,000 bushels; shipments, 70,000; No. 1 wheat dull at $1 67½ to $1 68; No. 2 do. at $1 53½ to $1 54. Flour nominal. Pork firm at $20. Freights unchanged.

Chicago Markets, Sept. 11, noon.—William Young & Co.'s report.—Wheat—Receipts, 36,000 bushels; shipments, not reported. No. 2 wheat quiet at $1 56½. Corn dull at 97½c.; receipts 77,000 bush.; shipments, 118,000 bush. Pork unchanged.

THE CANADA FARMER is printed and published on the 1st and 16th of every month, by the GLOBE PRINTING COMPANY, at their Printing House, 26 and 28 King Street East, Toronto, Ontario, where all communications for the paper must be addressed.

☞ Subscription Price $1 per annum, (POSTAGE FREE,) payable in advance. Bound volumes for 1864, 1865, 1866 and 1867, may be had for $1 30 each. Subscribers may either begin with No. 1 of the present Volume, or with the first No. of any preceding volume. No subscriptions received for less than a year, and all commence with the first number for the respective years.

CLUBS will be furnished at the following rates:—

TEN COPIES for..... NINE DOLLARS.
TWENTY COPIES for..... SIXTEEN DOLLARS.
FORTY COPIES for..... THIRTY DOLLARS.
ONE HUNDRED COPIES for..... SEVENTY DOLLARS.

To Agricultural Societies ordering more than 125 copies, THE FARMER will be sent at SIXTY CENTS.

THE CANADA FARMER presents a first-class medium for agricultural advertisements. Terms of advertising, 20 cents per line space. Twelve lines' space equals one inch. No advertisement taken for less than ten lines' space.

Communications on Agricultural subjects are invited, addressed to "*The Editor of the Canada Farmer*," and all orders for the paper are to be sent to

GEORGE BROWN,
Managing Director.

VOL. V. No. 19. TORONTO, CANADA, OCTOBER 1, 1868. POSTAGE FREE.

The Month.

OCTOBER, it has been well observed, "is regal, and walks the woods royally with great show of purple and crimson, while a veil of golden mist streams from the tiara of the queenliest of the months." The mean temperatures for this month are very similar to those for May, as will be seen by comparing the following table with that which appeared in our article on that month:

Stratford	47° 93'
Hamilton	50° 62'
Barrie	48° 82'
Toronto	49° 09'
Belleville	49° 58'
Montreal	45° 76'
Quebec	46° 26'
St. John, N.B.	44° 35'
Halifax	45° 00'

But if there be similarity between May and October in temperature, there is a very decided dissimilarity in other respects. The air is not Spring-like. It is not charged with the juiciness and stimulus that distinguish the season of growth. There is no show of young shoots, nor smell of wood and soil. Instead of the bursting forth of activity and life throughout nature, there is the hush of repose and the sense of leisure. It is plain that the year is composing itself to rest after its appointed season of toil and bustle. Peace broods upon the hills and valleys. Beauty shines through the mists of morning, and golden glory paints the sunset at even. The forests are decked in a coat of many colours, and all nature puts on holiday attire. Very graphically does Henry Ward Beecher portray this month in one of his "Star Papers." "October! Orchard of the year! Bend thy boughs to the earth, redolent of glowing fruit! Ripened seeds shake in their pods. Apples drop in the stillest hours. Leaves begin to let go when no wind is out, and swing in long waverings to the earth, which they touch without sound, and lie looking up, till winds rake them, and heap them in fence corners. When the gales come through the trees, the yellow leaves trail, like sparks at night behind the flying engine. The woods are thinner, so that we can see the heavens plainer, as we lie dreaming on the yet warm moss by the singing spring. The days are calm; the nights are tranquil. The year's work is done. She walks in gorgeous apparel, looking upon her long labour, and her serene eye saith 'It is good.'" This description is peculiarly applicable to the Fall season of Canada, and nowhere in the world, perhaps, is the splendid colouring of the dying foliage at this period of the year so striking or beautiful as in our Canadian forests. The marvellous hues that give our woods their autumnal beauty, so rich that a painter can scarcely depict them faithfully without laying himself open to the charge of extravagance, are chiefly due to the prevalence of the maple in our woodland scenery. No other tree can vie with this in the variety and loveliness of the tints which the foliage assumes in its departing glory. The oak, the elm, and beech, with their appropriate drapery add to the charm and grandeur of the scene. Nature puts on a royal robe well befitting the solemn repose that precedes the sterner reign of winter.

But amid this general restfulness, the farmer must not suffer his energies to flag. It is not for him to think of repose yet. There are autumn crops to harvest, and every endeavour must be made to house them in good order. The potatoes must be dug, and happy is he who has one of those newly-invented labour-saving machines known as "potato diggers." If there be any field-work more fit for a horse than a man, it is this tiresome, laborious, back-breaking toil of getting up the potatoes. It is important that fine weather be chosen for potato-digging. They will be less likely to rot if put away dry, and besides they are cleaner and better every way. They should be put into cool and well ventilated cellars, or into pits provided with air and drainage. The same observations apply to other root crops. Turnips will continue to grow through October, and as they will stand considerable frost without injury, harvesting may be postponed until November. Fruit must be gathered this month, and its value will depend much on the care exercised in the process. It should be hand-picked and handled as tenderly as eggs. Orchard trees are often bruised and injured by the inconsiderate use of ladders. This should be avoided, and at all seasons it should be remembered that a tree is a living thing, not to be treated roughly with impunity. Various improvements may be advantageously undertaken this month. We generally do our road work in spring, but in the New England States it was formerly, and for aught we know is now, done in autumn. Better still perhaps it would be to do something at the roads at both periods. We greatly need in all parts of the country a more thorough system of road-making. We go on shovelling the accumulation of the ditch and road-side into the carriage track as though decayed leaves and old turf would make good footing for iron-shod horses and iron-tired wheels. Rarely is gravelling and metalling undertaken except when a chartered company takes a stretch of road in hand to make money out of it, and then farmers pay for their whistle, when they might have had it for next to nothing were a wise system of statute labour pursued. The fact is, we are too niggardly of time, toil, and outlay on our roads, and do not properly appreciate their value, and the importance of their being well constructed and kept in good repair. October is also an excellent month for all such operations as grading, cleaning, trenching, draining, planting, or building stone wall. There is no better time for cutting timber than just when the leaves are ready to drop from the axils of the newly formed buds of the year to come. Firewood cut this month is represented to be more valuable for heating purposes than when felled at any other season, and cedar or other wood wanted for rustic work, will hold its bark better and be more durable if cut in October. Those who prefer to plant their shade or fruit trees in the fall, should have a care not to defer it too late. It is not needful or best to wait until leaves have actually fallen. If there is full ripeness of wood, and the leaves are beginning to drop, it is quite time to transplant if it is to be done in autumn. But we confess ourselves decidedly in favour of spring planting in the latitude of Canada. As observed last month, it will pay to bestow early and thorough attention on fattening stock. Their growth should never be checked by exposure to cold or by short allowance of food. It is advisable also to have all store and working animals in as good condition as possible at the beginning of winter. They will keep more easily for it, and come out in better heart when spring opens. Sheds, barns, and buildings of all kinds must be put in thorough repair before winter, or the comfort of stock will be diminished and the consumption of food increased. This is a good month for out-door painting. It is said to stand better if applied at this period than either during spring or summer. Let the work be done whenever it may, it is labor and expense well bestowed.

A variety of garden operations may be advantageously performed in October. Gathering and stowing of vegetables, manuring, ploughing and spading, that the soil may be mellowed by winter frosts, taking out of the ground bulbs that are tender, and planting hardy ones for early spring flowering; these, and various other odd jobs, will make the garden as well as the farm a busy scene during the present month.

Final preparations for winter must now be made in the apiary. Whatever shifting, uniting of weak stocks, feeding deficient stocks, and the like, may require to be done, should be delayed no longer. Hives should only be opened on warm, sunny days now, if any internal attention is needed, as bees are easily chilled, and do not quickly recover the effects of cold.

The Field.

Agricultural Productions at the Provincial Exhibition.

The Agricultural and Horticultural productions were exhibited in a spacious shed erected for the purpose near the Crystal Palace Building. For various reasons it was late before they were collected together, and before they were well in place the judges had to commence work. During the time they were thus occupied on the second day of the fair, all other visitors were excluded from the building, and it was not till some time on Wednesday that their task was completed. By that time the crowd of visitors was so great that a leisurely examination was not practicable. It is only possible therefore to give a general account of this department.

The display of grain, as was to be expected from the character of the past season and harvest, was excellent as regards the quality of the cereals. It is to be regretted, however, that there is not greater competition in what is the main business of every farmer. The premiums, especially those of the Canada Company, and the Association's prize for the best twenty-five bushels of wheat, are on a liberal scale, yet, if we are not mistaken, there were very few competitors for these prizes. This is the more to be regretted, inasmuch as the larger quantity required gives really a better test of the quality of the crop, and we are not sure that it would not be a great improvement on the present system to substitute rewards for the best field of any produce, in place of the best bushel, or the best eight or twelve samples. A market gardener can raise tremendous roots on a single rood of land, by an amount of culture and expenditure of fertilizers which the farmer could scarcely imitate on the wider scale of his acres. We would not, however, disparage the good sample in limited quantity. To say nothing of its being the most convenient, if not sometimes the only practical, method of display and competition, these experiments on a small scale teach us what can be done by labor and manure, and point the farmer in the right direction towards success in his more extended field. Still, we think an *addition* might be made with advantage to the present list of prizes, and awards made for the best field of any crop, the best orchard, or the best cultivated farm.

The recent Exhibition afforded evidence of the capabilities of the country for wheat raising, the samples of this grain being most of them of superior quality. Mr. John Hamilton, of Strabane, was well entitled to the honor of winning the Canada Company's prize for the best twenty-five bushels of wheat. He gained also the first prize for the best two bushels of both white and red fall wheat. The berries in all the samples were remarkably fine, plump, even, and of good color. If such grain were exclusively used for seed, our wheat returns would soon show a very different result from that of recent years. The second prize given by the Association was gained by Thomas Turnbull, of South Dumfries, for twenty-five bushels of Diehl wheat, which compared very favorably with any in the Exhibition. J. McEver, of Hamilton Township, who last year obtained this prize of the Association, has the third awarded to him, for twenty-five bushels of Scules wheat. Six years ago, we are informed, he purchased sixty-seven lbs. of seed wheat, and obtained as the produce in the following year four and a-half bushels, which he again sowed, and from the yield he gained the Association's second prize. In the next year (1866) he gained the third prize for this same variety; and in 1867 was again successful with it in obtaining the second prize, while the produce of the same seed obtained in other hands the first or Canada Company's prize, the grain having been put out a little greener than in Mr. McEver's field. We would congratulate him on his success, and trust that he will go on, not perhaps with the same seed, but with the same perseverance and careful culture, till he has gained the first place, which he has hitherto failed to reach. There were other good samples of fall wheat exhibited. Joseph Rymal, of Hamilton, obtained the second prize for two bushels of white wheat, scarcely at all inferior to that shown by Mr. Hamilton. It is, however, unnecessary, and would occupy far too much space to specify individual samples, especially as the prize list already published indicates in a great measure the meritorious exhibitors. The samples of spring wheat, notwithstanding the drought, seemed up to the usual mark.

The barley was good, nearly all of a bright colour, though some of it was lacking in weight. That shewn by Allan Bond, of Storrington, was especially fine.

There was not much competition in winter rye, but the samples were good.

The oats did not seem up to the usual standard, though some of the bags, both of the white and black variety, were, considering the season, very fine.

The samples of peas shewed less of the effects of the long drought than would be expected, but there can be no doubt the yield per acre would tell a different story.

Of field beans there was only a small but fair show.

There were some really fine samples of Indian corn, some of the yellow varieties being especially worthy of note. Some specimens shewn by Thomas Eastbrook, of Flamboro, and H. J. Brown, of Niagara, were particularly good.

The display of field seeds of various kinds was very limited, though this is a department that deserves every encouragement. It is one of great importance, and by no means the least lucrative field of agricultural enterprise. Mr. A. Thompson, of East Flamboro', obtained the first prize for the best bushel of timothy seed, and Mr. John Smith, of Burford, for clover seed. Samples of Alsike clover were shown by the President of the Association, T. Stock, Esq., of Waterdown, and F. M. Thomas, of Brooklin—the latter gaining the first prize. C. Holt, of Whitby, is another diligent cultivator in this department, and gained prizes for turnip, carrot and mangel wurzel seed.

There were fifteen bales of hops exhibited, for the best sample of which W. H. Bailey (of London) gained the first prize.

The display of field roots was, though not large as to quantity, really magnificent and astonishing in the size of some of the specimens. Mr. W. Burgess' display of mangel wurzel especially deserves emphatic notice. His success in raising these gigantic roots is due, we understand, to the application of night soil to the crop, and farmers as well as market gardeners should take note of the unappreciated value of this too much wasted fertiliser. The Chinese and Japanese should teach the "barbarians" of Canada a lesson in this respect. There were other splendid samples of the several varieties of mangolds, but none equal, taken altogether, to the collection of Mr. Burgess. In turnips, purple top, green top and skirvings were also exhibited. The grey stone and yellow Aberdeen were also represented, though slenderly as regards the number of exhibitors. T. Stock, Esq., of Waterdown, was as extra entries. In some sections, again, the competition was small, or *nil*.

Near the main entrance to the show grounds was the space allotted for Reapers and Mowers, which were shown by themselves—the other agricultural implements being displayed to the north and west of the building. Among the Mowers and Reapers, H. A. Massey sent from his extensive works at Newcastle a beautifully finished combined machine (Wood's patent); also a separate Reaper and Mower. These are all well known to the agricultural community of Canada, and the high appreciation in which they are held may be gathered from the fact that they have now been manufactured for several years in Canada, and that last year alone Mr. Massey made upwards of 500. For a still longer period they have been favorably known in the United States, where they take the lead, more than 23,000 having been made last year. Those manufactured by the Newcastle works gained first prizes at previous Provincial Exhibitions of 1865, 1866 and 1867; and at the World's Exposition at Paris last year, Wood's reaper gained the highest distinction, and distanced all others in competition. An excellent mower and reaper was shown by John Watson, of the Ayr Foundry, with a single reaper from the same place. Benjamin Bell, of St. George, sent a combined Mower and Reaper, with F.A. Ball's Ohio attachment for mowing. The reaper can either be used as a self-reaper or not, at pleasure. It cuts six feet in width, but the draught is said to be comparatively light, having been found under 200 lbs. at recent trials. John Scott, of Caledonia, was another of the numerous competitors in this section, and also sent a mower, and combined machine. The wheels in this are wider than most other machines, by eight inches, and great steadiness is gained in consequence. John Forsyth, of Dundas, exhibited two single mowers, and three combined machines on the Ball's Ohio principle, with some improvements of his own. Mr. Collins, of Guelph, showed his patent grain harvester. F. W. Glen, of Oshawa, from the Joseph Hall Works, showed the Dick's self-reaper, a combined mower and reaper, also a Wood's self raker. Yales & Co., of St. Catharines, exhibited a "Cayuga Chief" combined mower and reaper; also a mower, and a third implement with a self-raking attachment. In these reapers the pole is connected to the machine by a hinge, which relieves the horses' necks from considerable weight. They are also constructed with a revolving action to the finger bar, by which they can be made to cut close to the ground, when desired, or the points of the fingers can be raised up so as to clear rough ground and cut higher. This change is not effected by raising and lowering the finger bar and sickle perpendicularly, but by giving it a rotary movement on its axis, so that the points chiefly are elevated or depressed. Haggart & Brothers, of Brampton, showed a Ball's Ohio Reaper, with Dodge's self-raking attachment; also, a combined implement without the self-raker, and a simple mower. The rotary motion is also given to the finger bar in these machines. L. D. Sawyer & Co., of Hamilton, exhibited two combined machines, and also a mower. Lawrence & Co., of Palermo, had a Ball's Ohio combined, with self-raker, which is noteworthy, among other excellencies, for an improvement in the adjuster for raising the finger-bar, which is done by a wheel and axle instead of a lever, and considerable power thereby gained. Paxton, Tate & Co., of Port Perry, showed the Marsh Harvester, a machine which has been fully described in the Canada Farmer, and of whose merits we entertain a high opinion. It was to us a matter of surprise that it was not in some way distinguished in the award of the judges. The successful competitors—and the remark just made is no way disparaging to them—were Messrs. Massey, Glen, Haggart, Lawrence, Yale and Forsyth.

There was quite an imposing array of threshing machines, and second to none among these was Abell's splendid and beautifully finished thresher and separator, which has already gained such distinction, and given the Woodbridge work a high reputation in this department. The machine has been so often fully described before that it is scarcely necessary again to advert to its advantages. The side delivery of the straw carrier is peculiar to it. The guarding of the gearing and coupling is almost complete, and in this respect the only machine that rivals, if it does not eclipse it, is Hoggert's. The whole is a model of good workmanship and well-contrived machinery. The power used is Pitt's power, and the shaft that goes through is furnished with couplings at each end, so that the machine can be run from either side. Mr. Abell was again the winner of the first prize.

Haggart and Bros. showed an excellent machine with several recent improvements introduced, consisting chiefly in contrivances for economizing power and protecting the gearing, so as to diminish the liability to accident. In the first place, the wheels that drive the cylinder and other parts, revolve outward instead of inwards, so that the fingers or dress of an attendant could not be caught between them while in motion. The tumbling shaft is protected by a wooden sheath, within which it revolves, thus affording complete protection from these terrible catastrophes which sometimes happen from the dress being caught. Additional security is also gained by the manner in which the couplings are guarded, so that there are no projecting bolts. There is also a very convenient arrangement for delivering the grain, a point often neglected, and this part is effectually screened from dust and chaff blowing back into it, an accident which often happens in other machines to such an extent as to neutralize in a great measure the good effects of the separator. Another convenience provided by this inventor is a seat for the driver, which can be attached to the power or not at pleasure. For this excellent machine the second prize was awarded. Glen, of Oshawa, showed their thresher known under the name of the "Farmer Boy's Friend;" and Sawyer & Co. exhibited another, manufactured by them at their Hamilton works. In this machine the shaking motion communicated to the sheo is equally applied at each end, so as to secure an even lateral motion, in place of the oscillating movement usually observed. Their power is also made very secure by a wrought iron horizontal bar, which gives great steadiness to the working. The same firm showed an improved drag-saw and two kinds of chaff and straw cutters, one for hand use, and the other for either hand or power. Maxwell & Whitelaw showed their well-known machine called the Champion Thresher. The power used to drive this machine is the Planet power, and is entirely constructed of iron. They showed, besides, a small and very convenient power for use on the farm, which will be found well adapted for a number of purposes, such as sawing wood, cutting straw, &c. This firm exhibited other implements, which are noticed in their place.

Near these, the steam-engine of C. H. Waterous & Co., from the Brantford Works, was in full operation, and attracted immense crowds of interested spectators. This beautiful engine is constructed on the same principle as that exhibited last year at Kingston. It is sixteen-horse power, and is adapted to be used either as a stationary or portable engine. With this motive power were set at work a pony saw-mill, a lath mill and bolter, Hall's patent shingle mill, and a variety of grain-crackers and corn and cob-crushers. Within the same railed area this firm also exhibited a fine assortment of inserted teeth and perforated teeth saws. The Brantford engine and its accompaniments formed quite a feature in the recent, as it has done in former Exhibitions.

Not far from this centre of attraction was a novel machine invented by the enterprising manufacturer of Woodbridge, John Abell. This is a very ingeniously contrived affair, and will, if it works as it promises to do, supply a want much needed. It is adapted to cut an open ditch or drain for laying tiles. It will cut a ditch three feet deep, nine inches at the bottom and thirteen inches at the top. It is a very powerful machine, and strongly made. The driver rides on a sort of platform, and appears to have perfect control over his work, and can raise the cutting part away from the driving wheel, if it gets clogged, and remove the obstruction. This cutter cuts a furrow while the wheel referred to scoops out the dirt and carries it to a sort of deliverer at the top, which throws it on one side. The horses walk on each side of the ditch, two being able to draw the machine in light soil, while in stiff ground four are required. The whole depth is not dug out at one operation, but the same length of ground has to be gone over several times to finish the work. This may seem a tedious process, but the makers say that the machine will complete a mile of ditching in a day. We had an opportunity of seeing it at work, and our first favourable impression was greatly strengthened. In clay, it works admirably.

There was also on the ground a drain-plough or ditching-machine, manufactured by W. Van Buskirk, of St. Thomas. Gilmer and Burkholder showed a powerful stump-lifter.

At some distance from these on the ground, though first in the prize art, and of chief importance in agriculture, were ranged the Ploughs, of which there was a good show both in iron and wooden implements. J. Morley, of Thorold, showed one of iron, one of wood, a subsoil plough, and a double mould-board plough. J. Condey, of Bartonville, was the successful competitor for the first prize. —Stephenson, of Nassageweya, exhibited a strongly made plough of polished iron, the share of which is very solid, and fastened without bolts. J. Yocom, of Walpole, T. Chisholm, of Paris, and G. McSherry, are exhibitors in this class. The last named showed a plough with a strong iron arch connecting the mould-board and share with the beam and handle, in such a manner that they can, when required, be easily separated for the purpose of repair. For this implement the second prize was awarded. The same maker showed one with a wrought-iron beam attached to wooden handles. The coulter is also fixed and adjusted by an iron buckle with set pin. J. Watson, of the Ayr foundry, sent ploughs with McSherry's patent combination of iron and wood just alluded to. James Walker, of Whitby, Atkinson Brothers, Etobicoke, J. H. Grout & Co., Grimsby, sent similar implements. The exhibitors of wooden ploughs were A. Yocom, J. W. Needs, of Bowmanville, J. N. Davis, J. Lowrie, Sarnia, T. J. Hind of Wallacetown, and J. Morley.

Subsoil Ploughs were exhibited by J. Morley, and Atkinson Brothers; Double Shear French Ploughs, by J. Watson and J. Needs; Double Mould Ploughs by J. Chain, of Guelph, and J. Morley. Massey, of Newcastle, and Turnbull & Co., of Hamilton, showed Gang Ploughs.

There were a few rollers, J. Watson, of Ayr, showing one with a grass and sowing attachment.

Iron and wooden harrows followed next on the ground. Of these there was a great variety; that manufactured by Israel Kinney, has a peculiarity in the jointing first shown by him last year, at Kingston, and since followed, it would appear, by several other makers. By the socket-joint the whole can be taken apart and put together again very readily, so as to admit of easy removing in a waggon. The whole is held together by chains. T. Alexander, of Glenwilliams, showed an ingenious contrivance which dispenses with nuts. The head of the teeth is perforated with a square hole into which a square rod is thrust from the end, (one rod fastening several teeth). This rod, or bolt, passes through a sort of sheath or barrel. From seeing these and similar alterations merely on the ground, one can scarcely judge of their merits; actual trial is needed to determine whether they are improvements or not. Isaac Westcott, Bowmanville, James Pringle, East Zorra, John Foster of Flamboro', and Carr & Roblin, of Lindsay, showed harrows of various make and excellence.

Hay elevators were shewn in operation, some on the harpoon principle, and others as horse pitchforks. Of the former sort, E. A. Benson, of Amelissburg, exhibited one with a fixed pully attached, which seems to be an improvement; the teeth are also longer than usual, and the whole is made of wrought iron. G. H. Abrams, of Gananoque, had another harpoon; and horse pitchforks were shewn by J. G. Pensyck, of Grimsby; James Garret, of Malahide; George Ash and Leonard Richards, of Mt. Hope. The Judges had an opportunity of testing the merits of these implements by seeing them work.

In turnip drills, both handbarrow and horse implements, there was fair competition. James Soulan & Co. had a corn and bean planter, no other of the kind being shown. J. Watson, of Ayr, J. Dodds, of Beverly, and W. Walker, of Hamilton, were the principal exhibitors,—the last-named gaining a first prize. The circuit of the fair ground, which has been followed in the foregoing notice, now brings us back to the neighbourhood of the steam engine and large machines. There were two saw machines here, one manufactured by Mitchell, of Millbrook, which gained the prize at Kingston, and in which several improvements have since been added, for which the inventor has taken out patents. Near this was a modest machine, invented by an amateur machinist, Mr. J. P. Clarke, of Yorkville, and called the domestic saw mill. It is a hand saw machine, working a circular saw, and seems well adapted for family use. The ingenious inventor estimates that it could be made for $15.

We come new to the Horse Hoes and Cultivators. Of these there was a great variety. Two-horse iron Cultivators were exhibited by J. Lawrie, of Sarnia, and I. Westcott, Bowmanville. One-horse Cultivators were shown by J. Watson, of Ayr, R. Gray, of Dundas, J. Lawrie, of Sarnia, Isaac Westcott, Bowmanville, and Turnbull & Co., of Hamilton. Two-horse wooden Cultivators were shown by several of the foregoing exhibitors, and by C. Welton, of Haldimand, whose machine is provided with a seat for the driver, a luxury which we are slow to introduce into Canada. John Grout & Co. exhibited also in this section, and B. W. Walton had a combined Cultivator and Seed Drill. F. & G. Morgan, of Markham, brought to the Hamilton Fair, and gained the first prize for, a two-horse Cultivator, for which a prize was awarded at the Paris Exposition. This has a good arrangement for adjusting the balance so as to remove the weight from the horse's neck. It also possesses another advantage, that the shovels can be readily taken off and the implement is at once converted into an efficient grubber. Massey, of Newcastle, showed Summers' grain chopper, and another was also shown by the inventor. The first prize for grain chopper was awarded to Waterous & Co., for their Mill already mentioned.

A novel machine was sent by Atkinson Bros., which they call a Land-presser, and which they contend is a complete substitute for the drill. It is intended to be used after ploughing to prepare the ground for broadcast sowing, which is to be followed by the harrow for covering the seed. The implement shown is furnished with two large wooden wheels (more may be added) which, as they revolve, leave the land in furrows at regular distances, with the soil nicely compressed. Most of the seed sown rolls into these furrows, and what little falls on the intervals is mostly dragged in with the harrow.

Next fellow seed drills, all said by their inventors to be the best, and to be perfect. One shown by Mr. Thomas Evans of London, is adapted to sow turnip seed as well as cereal grain. Mr. Scott of Dundas has a combination for sowing grass seed, as also had Maxwell & Whitelaw's drill, a machine that is largely patronised by farmers, and that gained the first prize in Kingston, and the second at the recent Exhibition. An excellent drill is also exhibited by James Seadall, of Oshawa. A drill which has been a great favourite in the United States, has gained the first prize at the New York State agricultural show, and been specially commended by the U. S. commissioner of agriculture, is manufactured by Andrew Crosbie, of Dundas, and was shown here. It appears to feed very evenly, the quantity of seed being regulated by the speed of the revolutions, and this by appropriate gear wheels. The feeding apparatus is peculiar, simple, and adapted to sow fine or coarse grains, even as large as peas. There is no stir rod in the hopper, and when it becomes necessary to clean this out, it can be done more readily than in other drills. The present is the first year of its introduction into Canada, but upwards of 7,000 were made during the past year in the States. For this drill the first prize and diploma were awarded.

A miscellaneous collection of implements occupied a long open shed in this part of the ground. Here was to be seen an excellent specimen of a horse hay rake. It is manufactured in the States by B. C. Taylor, and was exhibited by the agent for Canada, Jas. Soutar, of Chatham. It is called the Taylor Sulky Rake, and is a well-made, and, we believe, thoroughly efficient implement, light and strong, easily managed, and raking the ground very clean. We have seen the same in use in the States. The first prize was awarded to Yale & Co. of St. Catharines.

Maxwell & Whitelaw showed here some very excellent straw cutters, two of them adapted for horse power, and two for hand use. The same firm exhibited also a root cutter, imported, we believe, from England—at all events the patent is English, and the machine has long been in use there. It is a thoroughly good implement, and by reversing the action of the crank can be made to cut fine for sheep or coarse for cattle. It is light, and occupies little space.

J. Watson, of the Ayr Foundry, shewed a similar machine and several straw cutters, and an admirable machine for cleaning peas, which is, in fact, a miniature pea thresher. L. D. Sawyer & Co., and Hind & Roberts were also exhibitors of straw cutters. John Abell, of Woodbridge, showed an excellent grain crusher, which is well adapted to grind large or small grain and seeds. It is somewhat similar to Summers', but the grooves in the rollers are more oblique, and the motion of the second roller is more rapid than that of the other, so that the grain is cut as well as crushed.

Cider mills are shewn by Sells, of Bayham. These are too well known to need comment. This exhibitor received again the distinction of a first prize. James Scott, of Dunbar, sent one somewhat similar; and Thomas Walker, of Westminster, exhibited one of altogether different structure, with a canvas attachment to strain the juice after the operation of grinding and pressing.

A number of washing machines were, as usual, on exhibition, and their inventors claim immense advantages for them. George Baker, of Oakville, showed one which in appearance is something like a root cleaner. A sort of barrel formed of bars, with open spaces between, revolves in a trough. A number of wooden balls inside the barrels are designed to assist in the process of cleansing. P. Forfar, of Waterdown, showed another on a different principle.

Fanning mills were very slenderly represented in the exhibition, but a very good one was shown by W. A. Geroldamy, of Tara, Co. Bruce. It is well got up in every respect, but the distinctive features are a wire agitator which stirs the grain through the bottom of the hopper and prevents choking, a screw which nicely regulates the feed, and the use of perforated zinc instead of wire sieves.

A few farm waggons, in no way remarkable, and a collection of dairy implements, noticed elsewhere, complete the contents of the implement shed.

On the rising ground west of the large machinery a number of pumps were displayed, most of which were fixed in place over tanks that had been constructed for the purpose, and supplied with water by the exhibitors. Mr. Merrils, of London, Ontario, exhibited a variety of so-called telescopic lift and force pumps,

adapted for domestic use, or for feeding tanks or fire engine purposes. These machines are also made in Toronto by W. Hamilton & Son. Mr. Powell, of Newton Brook, also showed specimens of his now well known pumps—among them the patent swing pump and the Dominion force pump, the latter provided with a double air chamber, and throwing a powerful and steady stream of water. This is the only wooden force pump made in Canada. His patent adjustable hose, which is very readily removed or attached, is a very convenient appendage to these contrivances. Other pumps were shown by Hiram Land, of Port Nelson, and D. C. Ferguson, of Scarboro'.

Some ingenious fences occupied the highest knoll on the Fair Ground. Stephen Washburn, of South Dumfries, showed his portable picket fence, models of which were exhibited at Kingston last year. To one of these he attached a gate, the hinge and latch of which are both ingenious. The gate will swing either way, can be easily raised to be out of the way of snow, and is self-latching. He has also a machine for turning and sharpening the pickets. With the aid of this the work can be done so fast that the patentee is able to supply the fence as low as fifty cents a rod.

B. Greening & Co. exhibited several varieties of their patent machine-made iron wire fences, which are light, strong, and tasteful in design.

Gates appropriately came next in order on the ground. R. E. Stephens showed a small gate, of ingenious contrivance. T. T. Munger exhibited some ingenious slide, or, as he calls them, friction roller-gates, to one of which is attached a most admirable contrivance, by which a person driving through can open and shut the gate without leaving his vehicle. Farmers, and all who have to be their own coachmen in muddy weather, will appreciate the convenience of this invention. Over the top bar is fixed a cog wheel, and in the bar a number of notches; a long iron rod or axis projects from the wheel on each side to a sufficient distance to allow room for the horse and the vehicle between the driver's seat and the gate. This rod is kept in place against a post at the side, and is bent into a handle, by which the wheel can easily be turned, and the gate is thus made to slide back and forth. Capt. W. James, of South Norwich, exhibited an ingenious gate, which has the recommendation of being cheaply made, and of being readily lifted over snow. Mr. R. Lewis, of Melbourne, however, obtained first and second prizes for his gates, with which the readers of the CANADA FARMER are familiar, from the descriptions and illustrations which have appeared in the issues of Sept. 2, 1867, and Sept. 1, 1868.

Other farm tools were to be seen in the Crystal Palace, and a few in the Horticultural shed. Among the former, Messrs. Whiting & Co., of Oshawa, had an excellent assortment of scythes, of different sizes, on exhibition. Three distinct kinds are made for grass, and the same number for cradle reaping. They had also well-arranged assortments of hoes and forks, among them socket forks and hoes, manure forks, with the strapped and the common ferule, and other agricultural implements. Mr. W. Lutes, Townsend, Ont., to accompany these, had several sets of very handsomely-finished axe-handles on exhibition. Mr. P. Washburn showed others, which were of excellent quality.

F. Johnston & Son, Elgin, were exhibitors of an assortment of tool handles of all descriptions, comprising hammer, axe, and sledge hammer handles.

Mr. J. Honrigan, Dundas, had a number of very finely-finished chopping axes on exhibition, with a number of reaping and mowing machine blades—all exhibiting the very best workmanship.

The above is but an imperfect sketch; little more, indeed, than a bare enumeration of a very admirable show of implements, which we examined as carefully as limited time and the hurry of Exhibition work would allow; and if articles of merit have been passed by, their owners will, we are sure, exonerate us from any intentional neglect. The prize list, which we shall publish as soon as it has been officially corrected, will, in some cases, supply the omission.

Crops in Quebec.

To the Editor of THE CANADA FARMER:

The drought which so afflicted the rest of Canada was continuous here for at least six weeks, around Quebec. It was, however, local, for during its height there were twenty-four hours' steady rain at Frampton, thirty-six miles from town. Also, in what are called *par excellence* the Eastern Townships, there was rain during the existence of the drought which prevailed in the neighbourhood of the city. The result is that the country generally has not suffered so much as was feared, and hay is rather low, ranging from seven to ten dollars a ton. Since the drought we have had beautiful dropping weather with warm winds, which have kept back Jack Frost so far, although he generally visits us before this.

What little wheat is grown about Quebec is most excellent, clean and heavy. Oats are a good crop, and are nearly all in. Turnips are a short crop, but are growing fast. The potatoes have too much top, but are quite healthy, and will certainly be an average crop. It is perhaps a strange idea to start, but I do believe people about here manure potatoes and meadow *too heavily*. The result with regard to the former is, that they are rank and will not keep. Cabbages are a failure, on account of the white butterfly. Would it not pay *well* for every county to purchase dead butterflies, at so much a hundred, of little boys? It would certainly be better than waiting for the eggs to develop to caterpillars before removing the evil. *Obsta principiis* should be the motto with regard to all these evils.

Among the crops that grow well down here are French beans. These should be more extensively grown, for they are a sure crop, unaffected by any insect, they produce a plentiful crop, and fetch a good price. But oh! how slow we are down here! These things command two dollars a bushel on the line, where the Americans buy quantities of them, and yet, not a *pint* of them ever leaves the Quebec market! Surely some old country man might find energy enough to grow half an acre of them as an experiment. They make an excellent winter dish by being soaked twenty-four hours or more before being boiled, slowly, till sett. Well done, they are excellent. Badly cooked, they are abominable.

Honey is good, but not so plentiful, on account of the dry weather. We have a flower show in progress, about which I will write next week.

PHIALA.

Quebec, Sept. 10, 1868.

NOTE BY ED. C. F.—Will the writer again favour us with his name and address, which we have unfortunately mislaid? We have not omitted to insert any communication which we have received, so that it appears his "last" has never reached us.

The Dairy.

Dairy Implements and Products at the Exhibition.

THERE was but a small display of dairy implements, showing some ingenious and most important inventions, truly, but in the number of articles falling short of the last two exhibitions, and by no means well representing the dairy interest of the country. Among the novelties in this class was a milk cooler, invented by Mr. C. G. Cody, which promises to supply a long-felt deficiency in the manufacture of cheese. By this apparatus the liquid poured into a sort of hopper, with a narrow slit along the bottom, falls in a thin sheet in front of fanners, the blast from which, mixing with the fluid and scattering it in fine spray, at once reduces its temperature, and deprives it of the animal odour, which is apt to affect injuriously the quality of cheese. The President of the Canadian Dairymen's Association, D. E. Chadwick, Esq., has expressed a very favourable opinion of the merits of this machine, which has also, we understand, received the approval of one of the best judges in such matters, X. A. Willard, Esq., of Utica. D. Harris is the exhibitor of another very simple, but most useful contrivance, called the curd drier. It is a large wooden tank or vat with the bottom sloping towards the centre, along which there is a perforated tin strainer, over a conducting spout. This arrangement allows all the liquid to drain away from the curds without the necessity of using cloths, a material very difficult to keep in that state of perfect cleanliness which is so essential to dairy operations. This drainer has now been in use about one year, and is becoming very general in the Oxford county cheese factories.

F. L. Bungay, of Norwich, exhibited and obtained a prize for his very excellent cheese vat.

There was quite a large assortment of churns, with a variety of devices for lessening manual labour. Among the exhibitors was J. W. Goodson, of Hamilton, who showed a barrel churn, with lever power and perforated dasher, an effective-looking machine, which is sold for $3.50. C. Lewis, of Salford, had a lever churn, the lever working on a roller, and the motion of the dasher being thereby rendered perpendicular. There is a coil spring attached to the back of the lever, which raises it, and relieves to a certain degree muscular effort in working. C. Stone, of Ancaster, A. Lean, of Cayuga, C. W. Jones, of Percy, R. Dickhout, of Dereham, and T. Taylor, of Waterdown, were also competitors in this class.

A cheese press was shown by R. Whitlaw, of the Oxford Foundry, thoroughly well constructed, and favourably known to cheese makers. John Arnor, of Hamilton, had another on exhibition, which is furnished with an eccentric lever acting on the top of the screw, weighted as required, so as to secure a continuous pressure. The same maker showed another of simple construction, which is a lever press without the screw. He had also an ingenious hand curd mill, in principle very like the sausage machines now so much in use. The foregoing comprise nearly all the dairy implements exhibited.

There was a fair display of factory and dairy cheese, T. Ballantyne, of Downie, taking the prize for the former, and T. McLaren, of West Flamboro', the first for the latter kind. Mr. Parsons, of Guelph, obtained a prize for his meritorious Stilton cheese. The competition in butter was pretty large, and the contents of some of the firkins and crocks of first-rate quality, such as rarely, if ever, finds its way into the Toronto market. The sample sent by Mr. Thompson, of Beverly, well deserved the prize awarded. This is a branch of the dairy interest that is a disgrace to Canada, and the meritorious exceptions deserve special praise. It would be well if some associated system like that of the Butter Factories in the United States could be introduced into the Province, so that the business might be conducted on scientific principles, and the markets of our large towns supplied with an article that would consign the execrable compound now vended to its more legitimate and ignoble uses of greasing rough machinery and waggon wheels.

The Apiary.

Bees and Bee-Hives at the Exhibition.

THERE was more than the usual amount of competition in this department. The principal exhibitors were A. D. Bacon, of Bayham, S. H. Mitchell, of Blanchard and J. H. Thomas, of Brooklin. The hive exhibited by S. H. Mitchell, of Blanchard, is like the Thomas and Bacon hives, constructed upon the movable-comb principle. The frames, however, are novel in their construction, being somewhat of a triangular form. Mr. Mitchell handled his bees with considerable skill, and is quite an enthusiastic bee-keeper.

J. H. Thomas, of Brooklin, as heretofore, had a large display of hives and bees, among which we noticed a very large and populous stock of Italians, and an observing hive containing a very beautiful Italian queen. We also observed some eighteen or twenty small boxes, which Mr. Thomas informed us contained Italian queens for sale. As usual, large crowds gathered round this stand to examine these very popular hives, and listen to the information given concerning the nature, habits and management of bees.

A. D. Bacon also exhibited several observing hives, containing bees and an Italian queen; we noticed, however, that his bees were hybrids.

Mr. Thomas again obtained the first prize, which he well deserves. He also received an extra prize for Italian stock, and another for Italian queens. The second prize for hives was awarded to S. H. Mitchell, of Blanchard.

It is pleasing to notice a growing interest in this direction, as was still further evidenced by the large display of honey, which was far greater than at any previous exhibition; there being eighteen exhibitors of honey in the jar, and eleven of honey in the combs. It certainly must have been a difficult task for the judges to determine which among several of the jars exhibited was worthy of the prize. The awards made by them were to the following gentlemen, in the order in which they are named:—For honey in the jar, Thomas Kirkland, Oneida; S. H. Mitchell, Blanchard; W. Ptolemy, Binbrook; G. W. King, Pembroke. For honey in the comb, H. M. Thomas, Brooklin; James Kirkland, Oneida; G. Bennett, Cobourg; and S. H. Mitchell, Blanchard.

Canadian Natural History.

The Crested Grebe.

(*Podiceps cristatus.*)

THE Grebes belong to a small group of birds, placed by some naturalists in a sub-order by themselves, intermediate between the Waders and Swimmers; but there is scarcely sufficient distinctive peculiarity to warrant their separation from the latter order, *Natatores*, to which they naturally belong. They are included in the family of Divers (*Colymbidæ*), the largest and most remarkable of which, the Great Northern Diver, has been described and illustrated in a former number of the CANADA FARMER. The Grebes, however, form a sub-family, which is distinguished by the toes being margined with a membrane, usually lobed or scolloped in its outline.

We have three native species, the largest of which is represented in the accompanying illustration. The crested Grebe is readily recognized by the peculiar appendage to its head and neck. The latter, or ruff, is peculiar to the male bird,—the two tufts of feathers on the head mark both sexes. This is a handsome-looking bird, measuring from eighteen to twenty inches in length. It possesses the characteristics of the genus in the bill of moderate length, straight, robust and pointed. The nostrils are broad. The neck is long and slender. The feet are placed very far back; the tibia, or leg bone, very short, and feathered to the joint, and almost hidden by the belly. The inner and middle toes are connected by a web, as far as the first joint. The female is of a lighter brown, approaching to grey. The sides of the head, as well as of the body, are tinged with a reddish hue. The chin and front of the neck are white, shading off to grey on the under part of the body. The tufts on the head and the ruff are, in general, black, tinged with green; the upper part of the ruff is of a reddish brown.

Like all water-fowl, this is a very shy bird, and chiefly frequents secluded ponds and inaccessible marshes, where, among the reeds, it forms its nest, and lays about four yellowish-white eggs. The young are very pretty little birds, covered with soft downy plumage, and boldly striped with grey and black from beak to tail.

Another and more common species is the Horned Grebe, (*Podiceps cornutus*) commonly called Dipper or Diver, a much smaller bird. This is a most active creature, defying most of its foes, even the arch enemy, man, by the lightning-like rapidity with which it disappears and dives beneath the surface of the water, where it will remain for an astonishing length of time, to emerge again, for the purpose of breathing, at some distant and unexpected quarter. It is no easy matter to shoot these birds; so rapid are their movements, that almost in the instant of time between the flash of the fowling-piece and the contact of the pellets with the water, they are down below "like a shot," as the saying is, and the disappointed sportsman perceives the water disturbed by the contents of his gun exactly in the right spot, but no bird dead or alive is to be seen. The flesh of these birds is sometimes eaten, but has a fishy flavor, which renders it unpalatable to most people. The feathers on the breast have come into very extensive use as ornamental trimming for various articles of female attire. A third species, the Red-necked Grebe (*P. rubicollis*) is rare in Canada.

Natural History Department of the Exhibition.

THIS very interesting department had the smallest exhibition that we remember having seen at any Provincial Exhibition; in fact the principal sections or classes of natural history were not represented. There was not a single entry of mammalia, birds or fishes; whether this was owing to the small amount awarded as prizes, or that our principal contributors to this department for this section of the Province, viz: Mr. Passmore, of Tronto, and Mr. McIlwraith, of Hamilton, are contented to rest on their laurels, it is difficult for us to say. We recommend, however, in future, that these gentlemen do still contribute to a department which is always so full of interest and importance to the visitors.

The collection of Canadian insects was very meagre, but we noticed the very fine cases of foreign insects sent from Toronto by Mr. Goswold. The moths and butterflies were collected on the Himalaya mountains, and probably are the most gorgeous in appearance that have ever been exhibited.

Mr. Wright, Hamilton, exhibited a very good collection of native minerals, for which he was awarded the first prize. There were also some very fine specimens of sulphate of baryta and lead ore, from the Galway mine, in the County of Peterboro.

Canadian plants were represented by a very fine herbarium, in a most excellent state of preservation, exhibited by A. Logie, of Hamilton.

There were a few small articles of natural productions, but none of importance, with the exception of some fine specimens of rock salt, for the use of horses and cattle, imported by Messrs. Hendrie & Co. of Hamilton.

Stock Department.

Stock at the Provincial Exhibition.

FOR the accommodation of the large number of animals entered in this department of the Exhibition, considerable alterations were made in the buildings on the show ground, and several new structures were erected. South of the Crystal Palace is an oblong plot of ground, in the centre of which an ample space was railed round for a horse ring, and beside this a smaller circle was set apart for a cattle ring. The three sides below the building were occupied as sheds and stables, those on the east side being appropriated to the shorthorn cattle; while along the south and half the west sides the stalls, provided with close doors, and forming very good stabling, were set apart for the horses, and the remainder, on the west side, for Hereford cattle. These buildings were all erected against the boundary fence, and were open only on one side, looking inwards. For the accommodation of the other breeds of cattle, spacious sheds had been erected west of the main building. These were divided into two rows of stalls, one on each side. The first of these was set apart for Devons; next to these was a similar shed, devoted to Ayrshires along one side, and Galloways and Angus cattle on the other. The pigs were accommodated in a similar long shed, with a double row of pens, one on each side. The sheep occupied pens along the eastern side of the grounds. The shed for the poultry was a very suitable structure, erected north of the building, and very near it; it was enclosed on all sides by slats or battens, and tightly roofed in. The accommodation was ample, convenient, and well sheltered from the weather, and the general arrangements were excellent. We proceed now to notice the different classes of stock, in their order on the prize list.

HORSES.

The show of horses on the whole was exceedingly good, and highly creditable to any exhibition. In the class for blood horses, however, the number of entries was very limited. The principal exhibitors were the Messrs. White, of Bronto. In the aged class, Mr. Waddell, of Hamilton, headed the prize list with "Rurie," a very fine bred horse, and by far the best specimen of a thoroughbred in his class. Some of the blood stock wanted substance.

In the second class, for agricultural horses, the show of aged stallions was very good. Mr. Ferris was again successful with his black horse. No doubt he is a very fine animal; yet it is our opinion that the chestnut imported horse, owned by Mr. Hawkins, of Markham, although he failed to secure a prize, was the best and most valuable animal in his class. He shows many excellent points, and is certainly deserving of notice. He was imported last season by Mr. Cochrane, of Montreal, who is deserving of all praise for his continued enterprise in bringing to this country such valuable animals.

Mr. Ferris also gained the diploma for the best horse of any age.

The brood mares and young stock generally, although a few very superior animals were exhibited, were not quite equal to former years. Mr. Armstrong, of Vaughan, and Mr. Berth, of Darlington, gained respectively the first and second prizes in the class for brood mares, and both were good specimens of the general purpose horse. In the class for the two-year olds, we observed a very fine mare, belonging to Mr. Smith, of Glanford.

There were twenty-two entries in the class of matched horses for agricultural purposes. Some very fine horses were shown. Mr. Coyne, of Trafalgar, was successful in obtaining a prize. Mr. Hendrie, of Hamilton, and Mr. Hall, of Blenheim, also showed excellent teams.

The heavy draught class was well represented, and many very fine specimens were exhibited. There were two imported three-year olds worthy of particular notice, one of them owned by Mr. J. J. Fisher, Colborne, and imported last season from Lincolnshire, England. The other was imported from Dumfriesshire, Scotland, and is the property of Mr. Thos. Evans, Blanchard; both of these animals showed symmetry and action seldom to be surpassed in this class.

The two-year olds were also very fine, and in this class, Mr. J. Thompson, of Markham, showed one imported last season.

Mr. J. Davidson, Pickering, had a very fine imported brood mare which has won many prizes in former years, and will yet, we believe, stand well forward on the list of prize-takers. He also exhibited an excellent two-year old filly out of the above mare. The latter obtained first honours. Among the principal exhibitors in this class were Mr. McFarlane, Pickering, who showed a one-year old colt, and Mr. Docherty, Scarboro, who had a good three-year old, bred by the late Mr. Torrance, Scarboro.

For aged stallions, Mr. Harvey's brown imported horse "Champion" gained the first prize, but competing for the diploma for the best horse of any age, he was beaten by a younger rival, already noticed. Brood mares and young stock were not so numerous as we have seen in former years.

For the best pair of heavy draught, Mr. Cochrane, Montreal, gained the prize with his pair of imported Suffolk mares, aged respectively three and four years. The heavy draught, as a class, were decidedly good, and it would be a very difficult matter to surpass them at any exhibition in Great Britain. In fact, many of the premium animals on the ground were imported, and have carried off principal prizes at exhibitions both in England and in Scotland. It is gratifying to find the spirit and enterprise of many of our Canadian farmers in importing such valuable stock, which in after years will be of universal benefit to to this country.

The carriage and driving horses were in great numbers. Mr. Davis exhibited his pair of black mares which has carried off the first prize on two former occasions. Mr. Irish, of Toronto, also showed a pair of excellent carriage horses. In the class for single carriage horses, Mr. Hendrie, Hamilton, showed a very fine bay gelding, which for action and substance can scarcely be equalled. He also exhibited a very fine saddle horse.

Of aged stallions there was a very fine show. There were about twenty animals on exhibition, and the whole of them first-class animals, many of them combining both symmetry and action, seldom to be seen. Mr. Douglass, of Oakridges, showed two very fine animals descended from the Old Royal George stock. Mr. Murray, of Toronto, exhibited Coachboy, who has stood high in the prize list in former years. Mr. Roach, of Hamilton, had a very fine animal, which the judges put first on the list; he is by Royal George out of Reindeer mare. Mr. Tench, of Niagara, was awarded the second prize, and Mr. Ellis, Hamilton, the third. The three year old stallions were a fair show. In this class, Mr. E. N. Orr, Georgetown, carried off the prize with a very nice-looking brown horse. There were several good pairs exhibited; but the general show of carriage horses was only middling.

CATTLE.

The show of cattle must be acknowledged by all capable of forming an opinion on the subject, to have been one of the best, if not the very best, we have ever had at a Provincial Exhibition. No fewer than 320 head were on the ground, and it says much for the growing appreciation of the Durhams, that nearly one-third of the number were of that deservedly popular breed. Including the grades, most of which are dashed with short-horn blood, more than one-third were of this breed. Of pure Short-horns, there were 97, and nearly all of them were choice animals. It speaks well for the judging at former shows, that inferior animals are now for the most part kept at home. It was a very delicate and difficult matter for the judges to decide in some of the classes on which of a number of animals of nearly equal excellence to bestow the honours. In other classes, the decision was of course very quickly made. The class of two-year old bulls was pronounced by the judges, and others, whose opinion is entitled to respect, the best ring ever collected on this side of the Atlantic. Had the three prize takers been removed from this class, it would still have been considered remarkably well represented. The judges would have liked, had it been possible, to have given all the animals a prize. The bull calves were another capital class, and contained no fewer than 17 competitors. Mr. Stone's "Grand Duke of Morton" is at the head of the list in aged bulls, and Mr. Cochrane's "Rosedale" in aged cows. Two of the last-named gentleman's recent importations, a yearling bull, and a heifer calf, attracted much attention, while there was much disappointment that the one thousand guinea heifer was not on the ground. Mr. Christie's herd was conspicuous only by its absence. Mr. Snell had a number of very fine specimens on the ground. So also had Mr. John Miller. The Devons and Galloways and Ayrshires were in nearly equal force and quality. Some 25 good Herefords were shown. Three Angus cattle only were exhibited. Twenty-four grades, the best among them owned by Mr. John Miller, showed the effect of short-horn crosses on our native stocks. Some very fair working oxen were shown, two pairs of high Durham grades being especially excellent. There were very few fat cattle, a huge steer bred by Mr. J. Vine, of St. Catharines, being the most remarkable. This animal was purchased by Mr. J. Britton, of Toronto, for $400.

In proceeding to give a somewhat more detailed account of this department of the Exhibition, we may observe that the plan adopted of having a separate ring for showing each breed while being judged has been found a great convenience to all concerned. In the centre of each ring a post is planted, from which there swings after the manner of a signboard the name of the particular breed of cattle to which that ring is devoted. Posts and ropes prevent spectators from crowding in upon the judges while in the performance of their duties, and enable a large number of persons to get a good view of the animals exhibited. To estimate fairly the comparative merits of the competing specimens, it is needful to see them side by side in the open air. Passing from stall to stall gives but a poor opportunity of coming to an intelligent and just opinion of the various animals. As, however, the judicial process goes on with the several breeds simultaneously, and unfortunately are not ubiquitous, it was impossible for us to see all the cattle under the most favorable circumstances. We therefore naturally concentrated our attention upon the Short Horns. Each year makes it manifest not only that this valuable breed is continually rising in public favor, but that our leading breeders, instead of being satisfied with past results, are constantly aiming at a higher standard of excellence. To possess the best specimens of this breed in America is not glory enough for them. They are ambitious of competing with and excelling the Short Horns produced in their native haunts. It is undeniable that some of the finest animals bred in Britain have been transferred to Canadian pastures, and the foundation laid for herds that may yet rival some of those that have become historical and famous such as we have ground to expect from not a few of our breeders—we may look forward to high distinction, if not victorious laurels, in the Short Horn ring of the world. There is, however, one serious difficulty to be overcome. Such are the traditional requirements as to the condition of Exhibition animals, that breeders find it necessary to feed them to a degree that is incompatible with their fullest efficiency in the parentage of choice stock. To be distinguished both in the show ring and the byre, a cattle breeder would need two sets of animals—one fed up to the exhibition mark and another kept down to the breeding point. Hon. David Christie assigns this as the reason why he has not shown his fine short horn herd for two seasons past; and on the same ground we understand Mr. M. H. Cochrane intends to withring, that in the quiet and retirement of domestic life at the farm she may bring forth descendants that shall maintain and even outshine the fame of their dam.

It is much to be desired that by some carefully framed rule as to the condition of exhibition animals this difficulty could be got rid of. As it is, breeding and showing are conflicting interests—a thing exceedingly to be regretted. If, however, this evil is to be remedied, some rule of uniform and impartial application must be adopted, since any single breeder would show under fatal disadvantages if his animals were sent into the ring in ordinary breeding condition to compete with highly fed rivals.

As already observed, the Short Horn department must be acknowledged to have made a very fine display. Among nearly a hundred animals of high general excellence, it is manifest that only a few can be particularized in such an account as this. But it would be unfair to conclude that those not specially noticed are unworthy of mention. Had a smaller number been shown, more in proportion would have come in for particularization. In the class of aged bulls there could be no question as to the superiority of Mr. Stone's Grand Duke of Morton. Mr. John Miller's Prince of Bourbon is a meritorious animal, and deservedly took the second prize. There were eleven entries in the three year old class—the first prize-taker being a fine bull sired by Oxford Lad and bred by J. Cowes, Esq., of Waterloo. His present owner is Mr. George Wood, of Downie. The two-year-old bull class was a very difficult one to judge, from the large number of superior animals comprehended in it. There were fourteen entries, every one of which was worthy of a prize. The animal that took the highest honors was imported by Mr. Snell, from Kentucky,. He was bred by Mr. Abraham Reneck, and is owned by Mr. William Collum, of Hayesville. The yearling bulls were a good class, though not equal to the two-year-olds. Bull calves to the number of seventeen were exhibited, and were felt to be a hard class to judge, from the uncertainty of development in animals of so early an age. An imported calf of Mr. M. H. Cochrane's won the first prize. Not the least perplexing competition was that for the sweepstakes. Mr. Stone's bull, the Grand Duke of Morton, gained the enviable distinction, but many thought Baron Booth—Mr. Cochrane's imported yearly—better entitled to it. He is certainly a young bull of remarkable excellence and great promise. In aged cows, Rosedale, of course, distanced all competition. Mr. Cochrane, in importing this magnificent cow, walked at once to the highest place of distinction in her class. Mr. Stone's Maid of Guelph, and Mr. John Miller's Lorena, followed next in order. In the three-year-old cows, the judges astonished most people, and nobody more than the fortunate owner, in giving the first prize to Gola, a recent importation of Mr. Jno. Miller's. "Blood will tell," and this cow being of nearly pure Booth blood, could not be put in any other position than the first. But for this she would have changed places with Mr. Cochrane's Maid of Athol, which was awarded the second. Mr. Stone's Isabella XII won the third place of honor. In the two-year-old class, Nelly Bly, a beautiful heifer, the property of Mr. John Miller, won the red card, and the distinction was grudged by nobody whose opinion is worthy of regard. She is an importation from Illinois, and if she does well will be heard from at future exhibitions. Mr. Cochrane's Miss Margaret Third, bred by Mr. Stone, took the second prize, and Mr. Stone's Cambridge Eighth, the third. The yearling heifers were a very fine class; Mr. Snell's Clara Barton, a very pretty animal, heading them by all odds. Mr. G. Robson's Fannie, third; and Mr. Stone's Miss Margaret Fourth followed suit. The heifer calves comprised fourteen first-rate specimens; Mr. Cochrane's recent importation of Wharfdale Rose got the first premium; she was sired by the same bull as Duchess 97, the 1000 guinea heifer, and cost 100 guineas; she is a heifer of grand promise, having a splendid chest, broad escutcheon, and other fine points. Mr. Stone took the second and Mr. Snell the third prize in this class.

The Hereford classes comprized a very select lot of animals. Mr. Stone is no longer left alone in his glory with this breed. Mr. Cochrane competes with him very sharply, though it must not be forgotten that Compton Lad, the finest specimen in his herd, and perhaps the most perfect bull of any breed on the ground, was bred by Mr. Stone. Mr. W. Perdue, of Chinguacousy, had the high honor of winning from both these gentlemen the first prize for aged Hereford bulls and the sweepstakes; his Sir Benjamin is a noble animal; he also was bred by Mr. Stone.

The Devons and Ayshires comprehended a number of meritorious animals; indeed the show in both these classes was of great excellence, and we regret that we cannot now go more fully into details. Some really beautiful animals were shown by R. Spooner, of Kingston, W. & J. Peters, of London, H. Spence, of Brooklin, and other successful exhibitors. In the Ayshire class Mr. W. Wheeler, of Woburn, was the most distinguished exhibitor, and gained fresh laurels for his choice herd of this useful breed. Most of the

Galloway honours were carried off by Guelph, and were divided pretty nearly equal between Messrs. T. McCrae and Wm. Hood.

The chief interest in the competition among cattle-breeders centred in the PRINCE OF WALES' PRIZE.

This was offered for the best herd, one male and five females, of any breed. Second and third prizes were offered by the Association. Fourteen entries were made for these prizes, but only six herds came to the scratch. Mr. Stone, of Guelph, showed a short-horn and Hereford herd; Mr. Cochrane, of Compton, did the same; Mr. John Miller, of Pickering, showed a shorthorn herd; and Mr. W. Hood, of Guelph, a Galloway herd. The Judges had a long and thoughtful time over this prize, and finally awarded the Prince of Wales' Prize to Mr. M. H. Cochrane's herd of shorthorns, the second prize to Mr. John Miller's herd of shorthorns, and the third prize to Mr. F. W. Stone's herd of shorthorns. The reasons for this decision will be gleaned from the following remarks, appended by the Judges to their award:—

"In reference to the Prince of Wales' Prize, the Judges make the following remarks: The committee have had great difficulty in coming to an accurate conclusion as to the superior merits of the herds submitted to their inspection, on account of the different breeds of animals competing on equal terms with each other; the different breeds submitted, viz., Shorthorns, Herefords and Galloways, each of the three possessing valuable qualities. Such diverse breeds should never be submitted on equal terms for prizes. Each are valuable for certain soils and surfaces of our country. The Shorthorns are, beyond question, the most popular, and probably the best breed of cattle with the majority of our stock breeders and graziers: yet there are large districts of country where they prove inferior to either the Herefords or Galloways. So with either of the latter herds—each of them the best of their kind. Suffice it to say we have given our awards under most embarrassing circumstances; and, had we fully considered the difficulties of the case before us, we would have hesitated to act on this committee.

"Under all circumstances, we beg leave, with due respect to the better judgment of the Managers of the Board of Agriculture, to suggest that hereafter prizes be offered for the best herd in their general classes, and that each herd be exhibited in a class by themselves, under whatever names they may be known."

SHEEP.

There was a fine display of sheep, especially of the Leicester and Cotswold breeds. Indeed this department of the Exhibition was unquestionably in advance of all preceding shows; and it is doubtful if so valuable and choice a collection was ever before got together west of the Atlantic. Owing to the peculiarly unfavorable season just past, there were very few lambs on the ground of any breed, and they were mostly under size. During the unprecedented hot and dry term, ewes could get no grass, and the lambs were not able to take any food but milk. Most of our flockmasters were obliged to eke out the scant pasturage by resorting to cured clover and meal as in the winter time. A few unusually good lambs that were shown owe their superiority to extra feeding of the ewes, and extraordinary painstaking. The older sheep generally had a healthy, thriving look, notwithstanding the torrid ordeal through which they had passed. As usual, there were some over-fat specimens; but for the most part no complaint can be justly made on this head. There is no perceptible appearance of improper shearing, and if it has been practised at all, it has been done so adroitly that it cannot be detected even by experts. So far as Leicestors and Cotswolds were concerned, the look of the sheep and the alleged date of shearing corresponded. The firm application of the excellent rule of the Association on this point has already wrought a most satisfactory improvement—rather a complete reform.

The Leicester classes must have given the Judges much perplexity from the uniform excellence of many of the specimens. Two pretty distinct types of this breed were shown by our flockmasters—the original and strictly true Leicester sheep, and the improved Leicester, obtained by crosses with animals of larger frame and longer and more lustrous wool. The Lincoln is the favorite for this cross, though there is reason to suspect that in some cases the Cotswold is resorted to for the purpose. These long lustre-wooled sheep are demanded by the American trade. It is this combing wool that United States manufacturers want, and had we a reciprocity treaty our flockmasters could sell a very large number of breeding animals of this sort. As representatives of the normal type of Leicesters, a pair of two-shear sheep imported by Mr. W. Oliver may be mentioned: they were bred by Miss Stark, of Mollinden. This lady is considered to rank about second among the Leicester breeders of Britain—Lord Powell, of Merton, near Kelso, taking the lead. Mr. Oliver's importation is a very choice one; and these animals, for symmetry and fattening tendencies, could not be surpassed, though they lacked the length and lustre of wool above mentioned. Mr. Cochrane had also several imported Leicesters that were very choice specimens of the breed as found at home. Mr. Snell, of Edmonton, had a very fine lot of improved Leicesters that might be taken as models of the sort of animals demanded by the trade of this country. Could we particularize we might mention several of his sheep—especially some very fine shearling rams—that deservedly attracted much attention. A very fine two-shear ram has just been sold by Mr. Snell for $250 to Mr. George Robson of London township. An aged ram imported by Mr. Kirby, of Milton is a very fine animal. Mr. John Scott, of Lobo, had some of the best ewe lambs this year has produced. Robert White, of London, had a very fine lot of Leicesters, of various ages—twenty-two in all. Mr. B. Charlton, of London, showed a pair of handsome ewes, and a very pretty pair of twin ewe lambs. Mr. C. Walker, of London township, who may be called the Leicester patriarch of Canada, had seventeen very nice specimens. A pair of his lambs excelled all the others on the ground, and the ewe lamb would be hard to beat any year, however favorable. Mr. Kirby, of Milton, had a fine lot of Lincolns and Leicesters. For want of a distinct Lincoln class in the prize list some Lincolns were merely ticketed as "extra entries," while others were shown among the Leicesters. Among the Cotswolds the first place must be assigned to the imported animals exhibited by M. H. Cochrane, of Compton. His aged ram is a splendid animal, and, what is a feature of great merit, not too fat for service. The same may be said of his ewes. These animals ought to have had the first honors; but they were given to an over-fed, though well-built, ram of Mr. Stone's, and to a pair of ewes that are advanced in life, past breeding, fed for the butcher, and fit only to be shown as fat sheep. Mr. Cochrane's shearling ewes took both first and second prizes. Mr. John Miller had a fine lot of imported Cotswolds. Indeed, this is one of the most valuable importations of sheep ever made into Canada. They consist of fourteen shearling rams and twenty ewes. All the rams were on the ground, but only five of the ewes were shown. These choice sheep are from the flocks of Messrs. Garne, Lane, Hower, Tems, and Gillet, all noted Gloucestershire breeders of Cotswolds. One of these rams has been sold to Mr. J. J. Dodge, of Ashtabula, Ohio, for $220. This gentleman also bought two ewes of Mr. Cochrane's, we did not learn at what figures. Mr. Cochrane has imported no fewer than forty-five Cotswolds the present season, and is certainly worthy of all honor for the spirited manner in which he is pressing his way into the lists as a breeder of first-class stock. In Southdowns, Mr. Stone deservedly carried nearly all the prizes. He has, indeed, a beautiful collection of this breed of sheep. A few very nice Shropshire Downs were exhibited, the imported animals owned by Mr. Cochrane taking the lead very decidedly. A pair of two shear ewes of this breed are the gems of this flock. An aged ram is a good animal, but rather Southdownish in look. This remark applies to the collection of Shropshire Downs exhibited by Mr. H. H. Spencer, of Brooklin. They are a fine lot of sheep, but partake very visibly of Southdown characteristics. The Cheviots did not nor do not show face at all; and the Merinos were but slenderly represented, Mr. Smith, of Burford, and Mr. Jamison, of Vaughan, carrying off the largest share of prizes. This notice is but meagre of the various sheep classes. To have done justice to the several meritorious individuals would require our whole sheet.

PIGS.

This department of the exhibition, so far at least as numbers are concerned, was quite below what it ought to be in a situation so central as that of Hamilton. It is natural to expect a show numerically inferior at Kingston, which approaches the eastern borders of the Province, and yet the number of animals in this class exhibited there last year exceeded that of the recent exhibition. It is evident that the chief attention of our stock raisers is devoted to the nobler animals, and that the hog has rather been neglected in Canada. There were, however, some good specimens here of the various breeds of swine, and the enterprise of several exhibitors, and especially Mr. George Roach, of Hamilton, in importing fresh stock, is highly to be commended.

In the large breed section the Yorkshires come first, and here among a few meritorious specimens there were some coarse animals that might suit the requirements of breeders in the Western States, perhaps, where size and weight for the market are more considered than symmetry and quality, but which would have a bad influence on Canadian stock. The principal exhibitors in this section were J. Brodie & Son of Prince Edward County. They showed six animals and gained five prizes. The best boar over one year, shown by them, was imported from the United States, where last year it obtained the second prize at the New York State Fair in Buffalo. Both it and that which gained the second prize are splendid boars, though the first was not equal to the latter in condition, nor indeed, to our thinking, in other points. Their young sows were also fine animals. Mr. J. J. Biggar, of Trafalgar, showed a fine boar. J. Featherstone, of Toronto, and J. Main, of Trafalgar, and W. Bethel, of Thorold, were also meritorious exhibitors in this class; but we decidedly preferred Mr. Main's Berkshires and Suffolks to his Yorkshire pigs.

In large Berkshires there was a considerable falling off in the number of entries, owing, perhaps, to a growing preference for the smaller breed of improved Berkshire. These animals were not kept sufficiently distinct, but were mixed up with others in a way rather confusing to visitors. J. H. Laurie of Barton was the principal exhibitor, and came off with the lion's share of honors in this section. John Corrie of Dereham, another successful breeder, had also some fine animals of this breed, and obtained the first prize for a well-built and good-looking sow, in too high condition for breeding purposes, however, which is perhaps a disadvantage always more or less incident to female show animals. These well-bred Berkshires also take on fat with a very little encouragement. R. Spooner and J. Featherston, of Toronto, and Hugh Dempsey, of Downing, had good specimens of this variety.

Other large breeds, crosses apparently of Chester or Yorkshire and Suffolk, were shown by Messrs. Main, Featherstone, Roach, Biggar, Marshal (Hamilton), Grant (Hamilton), and W. Thompson of St. Catharines. A large and very fine sow (for which a first prize was awarded,) shown by Mr. George Roach, of Hamilton, was, we understood, a recent importation.

In small breeds the Suffolks were well though not numerously represented. The most noteworthy animals in this group were a boar and sow imported from England by Mr. Roach, and which are desirable acquisitions to the country. J. Main, of Trafalgar, was also in force here, and deservedly gained several first prizes. J. Featherstone and Husband divided the remaining honors.

The improved Berkshires were here in larger numbers than any other special variety, and amongst them several excellent specimens deserve notice. Mr. Roach is an importer in this class also, and he exhibited two beautiful animals, recent acquisitions from England—a young boar and sow, which deservedly took first prizes. John Corrie, of Dereham, long known as a successful breeder of this variety, had here some choice specimens; in particular a young sow, which took the second prize. Some of the stock shown by other exhibitors were also either purchased from him, or the progeny of hogs raised by him.

Mr. John Snell, of Edmondton, was an exhibitor in this class, and showed a remarkably fine young boar, only six months old, but with promise of a very fine animal. It gained the second prize, being distanced only by Mr. Roach's older and imported boar. John Crumb, of Darlington, showed one of the best boars on the ground, bred from Mr. Corrie's stock. A sow from the same litter obtained a second prize. Mr. Featherstone, Mr. Stone, of Guelph, and Mr. C. Jones, of Ancaster, also showed some good specimens of the breed.

The remaining section—Essex and other small breeds—had very little Essex to show; indeed most of the animals exhibited under this head were Mongrel Suffolks. Mr. Roach showed the only Essex hogs, and they were very good. Messrs. Main & Featherstone were exhibitors in this class. Mr. Thompson, of St. Catharines, showed the best boar over one year old, and Mr. Edmondson, of Brantford, the best sow in the same section. Very few of the specimens call for any special remark. The accommodation prepared for the swine seemed more ample than was needed, and a number of the pens were occupied by Merino sheep, others were vacant, and a few were taken possession of by the attendants. One of these lay stretched, in profound slumber, at the back of a pen, and created no small amusement among the spectators, who scarcely looked for a specimen of the *genus homo* in such a place. It will be necessary to make some alterations in the pens for any future exhibition, to prevent the escape of the animals. Many of the attendants barricaded the front of the pens appropriated to their charge by the unwieldy cases in which the hogs had been brought to the ground; a precaution which greatly obstructed the view, and was not a little inconvenience to the visitors.

Correspondence.

Sorghum Syrup—Bee Moth—Hawthorn.

To the Editor of THE CANADA FARMER:

SIR,—I see by the numerous applications for Sorghum seed this spring, that the people of Canada are beginning to take an interest in the growth of that plant; and as I have grown it for the last four years, I propose to give you a few words on the subject of its manufacture.

As soon as the seed gets black, or before if the frost comes, take a stick, about two feet long, and knock the leaves off; and with a reaping hook remove the heads, and then cut the stalks off close to the ground, lay them in the waggon-box, and draw them to the cane press, where the juice is pressed out. Take the juice and put it into a sugar-kettle, and boil it down to molasses, keeping it carefully skimmed all the time, as the quality of the molasses depends in a great measure upon the skimming. Then wash the pot carefully and fill it again, and proceed as before, being careful not to fill up the pot, as in making maple syrup. The press is a simple structure consisting of two wooden rollers about one foot in diameter, and sixteen inches long, standing upright, with cogs in one and mortices in the other, at the top of the crushing part. Three of the ends of the rollers are turned down to about six inches, and the other end is left larger and longer, to put the sweep on. The whole length of the longer roller will be about thirty-four inches, and the other twenty-four inches. These rollers run in four-inch planks, both top and bottom, which are held held together by a little frame at the end of the planks, they being about six feet long. The rollers are tightened together by means of a wedge outside the plank. Every farmer should have at least an acre of cane, as the molasses is better than golden syrup. The cane is crushed by a horse hitched to the sweep.

Permit me, also, to say a word to my bee-keeping friends of Canada. As the Bee Moth is a great annoyance to bee-keepers generally, it occurred to me three years ago that if the moths were so anxious to get inside the hive they would collect on combs outside; I therefore put two pieces of fresh comb in front of the hives one evening. I went to it the next morning and killed twenty-five moths; and a lot got away. The morning following I killed seventy-five moths, and have not been annoyed with them until this year, when I tried the same remedy with like results.

I see by your paper that the subject of live fences is occupying the attention of the farmers of Canada, and as there is a great variety of thorns growing wild here, two of these I think would make excellent hedges, for the following reasons:—1st. Their close compact nature. 2nd. Their rough bark, which resists the attacks of mice. 3rd. Their formidable thorns. One of these I shall call the Laurel Thorn, from the fact that its leaf is very like the Laurel leaf, smooth and glossy. I will enclose a leaf and a thorn of each of the two kinds I think the best, and if you think there will be a demand for plants, I will raise some for sale. I have the English Thorn bearing haws, but they are not to be compared with the Thorn before mentioned.

WM. HOSKINS.

Sarnia, Sept. 1868.

NOTE BY ED. C. F.—Several species of Hawthorn, (*Crataegus*) are indigenous and common in this country. Two of them, the scarlet-fruited Thorn (*C. Coccinea*) and the Black or Pear Thorn (*C. tomentosa*), have the leaves deeply toothed on the edges and more or less cut and jagged, besides other characteristics whereby they can be readily distinguished from the Cockspur Thorn (*C. Crus-galli*), the leaves of which are regular in form, having an ovate (egg-shaped) outline, slightly serrated at the margin, and shining on their upper surface. The spines or thorns are strong, slender and sharp, and sometimes are as much as two inches long. This is probably the best of our native species for hedges. The leaf and one thorn enclosed with the above letter belonged to this variety, the second thorn most probably to one of the other two.

CHINESE YAM.—J. Emery is recommended to communicate with Mr. Prince, of Flushing, New York, on this subject.

PEAT.—Mr. Angus Shaw brought to this office a specimen of peat found on his farm in Lakeside, Oxford County. He says there is apparently an abundance of it in that neighborhood.

ESTIMATED COST OF BUILDING.—A subscriber asks us to give the estimated cost of such a building as that for which we gave a design in the issue of Aug. 15. Such a house could be put up in wood for about $2,000. Built of brick it would cost about $3,000.

POISON IVY.—Mr. Charles Mungham enquires whether all the so-called Ivy found growing on stumps, fences, &c., is poisonous; "some of it" he observes, "has three, and others five fingers to each leaf." The most common native creeper, very much resembling in general appearance the poisonous plant in question, is the Virginian Creeper (*Ampelopsis quinquefolia*) which is quite harmless, and belongs to the same natural order as the grape vine. The Poison Ivy (*Rhus toxicodendron*) is a plant of the Sumach tribe, and is readily distinguished from the preceding by the leaves having only three leaflets, while the Virginian Creeper, as its specific name (*quinquefolia*) implies, has five.

The Canada Farmer.

TORONTO, CANADA, OCTOBER 1, 1868.

The Provincial Exhibition.

THE Provincial Association of Ontario may justly claim the hearty congratulations of the friends of agriculture on the successful issue of their twenty-third Annual Exhibition. Looking at the number of entries, the high standard of excellence attained in many of the departments, the good order that prevailed, the increased and improved accommodation, and the excellence of the arrangements and general management of the whole affair, we are constrained to pronounce the recent Exhibition one of the best—if not the very best—that has ever been held in the Province. Great praise is due to the authorities of Hamilton, the local committee, and the officers of the Association, for the energy, judgment and good feeling manifested on all hands; and in the subordinate ranks, the superintendents of the various departments, whose offices have proved no sinecure, are worthy of all commendation for the manner in which they have discharged their onerous duties. All the authorities concerned have shown a laudable consideration for the interests of exhibitors and the convenience of the public; and have even stretched the spirit of leniency and accommodation in some matters almost too far; for no one will deny that the general work of the Exhibition would be materially lightened, and the comfort of judges, reporters, and the public enhanced by a stricter enforcement of the regulations regarding the time of bringing articles to the ground. If all infringements of these rules, and reprehensible procrastination, were followed by a forfeiture of the privilege of competition, exhibitors would take care to send their articles in good time, and much of the hurry and crowding of work would be avoided. Indeed but for the judicious sub-division of labor, it would be quite impossible to get through the amount of work in the very limited time allowed. Fortunately for the success of the exhibition, the weather during the preliminary days of preparation and the two principal public days was fair and pleasant, so that the vast crowds that thronged the Crystal Palace and the show-ground had an opportunity of making their survey without the drawback of the drenching rain that has hitherto so frequently marred the enjoyment of these occasions.

The most serious disadvantage attending these shows is the inevitable crowding on the two public days. This is not only a great discomfort, but renders anything like a proper inspection quite impossible. How to avoid this yearly increasing inconvenience is a problem that will force itself on the attention of the Association, and must ultimately lead to some modification of present arrangements. This difficulty affects chiefly the departments within the main building and the erections for the display of Agricultural and Horticultural products. The facilities for inspecting implements and stock were very much better, and perhaps all that could be accomplished in the limited time.

The gratifying progress that the science of agriculture is making in the Province, as evident by these Exhibitions, must be manifest to all, and should stimulate us to press forward in the path of improvement. It is not too much to say that every department of the recent Exhibition showed some signs of this advancement; but it has been most marked, we think, in the quality of the stock, and in the number, variety and excellence of the implements displayed. The show of Short Horn cattle, and Leicester and Cotswold sheep, has never been equalled in Canada. The Horticultural department is also one of growing interest and magnitude. The position and prospects of the Fruit Growers' Association are greatly improved, and indicate a career of prosperity and usefulness.

The progress in Art and Manufactures is also very marked, and elicited the admiration of not a few strangers from the adjoining States, amongst whom were some high in official position, and every way qualified to form an impartial judgment. Long may these peaceful arts be the only rivalry between our neighbors and ourselves.

The Harvest.

THE Grand Trunk authorities have this year, as on former occasions, gathered through the agents at their different stations reports of the state of the crops and the general character of the yield and quality of the different farm productions throughout the country. The account is interesting, but, for the present at least, cannot, for want of space, be given in full. We however present a condensed view of all that is most important, from which we believe our readers will have a distinct idea of the estimate formed of the harvest in the districts through which the Grand Trunk passes. For convenience of reference the whole range of the Grand Trunk is divided into the following districts: I. THE BUFFALO AND GODERICH. II. THE WESTERN. III. THE CENTRAL. IV. THE EASTERN, and V. That of QUEBEC AND RIVIERE DU LOUP.

I. In the first district, viz., that of Buffalo and Goderich, the reports of the different crops are tolerably uniform throughout. The fall wheat, without exception, has been an excellent crop. The very lowest yield mentioned is fifteen bushels an acre, and that only in one report; while other cases are mentioned where the return has been as high as thirty-five. We should say that the average throughout the district would appear to be from twenty-two to twenty-five bushels per acre, and a very fine sample of grain. The early sown spring wheat seems, in certain localities, to have suffered considerably from drought

and midge, and, in some instances, is spoken of as a failure. Still, with few exceptions, it will yield from ten to fifteen bushels per acre, and the breadth sown is considerably larger than in average years. Barley is spoken of as a light crop, though in some instances the yield is as high as thirty bushels per acre. The same thing is to be said of oats and peas. Upon the whole these coarser grains are rather under the average, on account of the drought, but not to such extent as might have been expected. Hay is generally heavy; and root crops, on account of the dryness of the season, almost a failure in some cases, and light in all; but the late rains may still, in some measure, remedy this.

The reports for the western district, which extends from Sarnia to Toronto, are generally of the same character. There is not a single report which speaks of the fall wheat crop in any but the most favourable terms. The yields mentioned range from twenty to forty bushels per acre, and the sample is of the best description. The spring wheat is, as in the other district already referred to, not so good. Yet it is not, except in very rare exceptional cases, to be spoken of as a failure; and, but for the contrast between its yield and that of the fall wheat, would be almost regarded as a fair satisfactory crop. Root crops are generally spoken of as poor, but the hay is very abundant. Over such a wide extent of country there will of course be considerable diversity, but in general the coarser grains, barley, peas, &c., are rather, if anything, below an average, though in very few instances, indeed, spoken of as a failure. Flax seems, upon the whole, to be about the same as last year.

In the middle district, extending from Toronto to Montreal, the same story substantially is told. From Toronto to Bellcville there is not one report which mentions the fall wheat as below an average crop, except in the case of Newtonville, where, however, it is still said to have averaged about twenty-five bushels an acre—not so bad as things go. At Bellcville the winter wheat is said to be poor in quantity, but the quality good. From this port downwards but little fall wheat is raised, but what was grown seems to have turned out well. The spring wheat is generally represented, as in other districts, to have been injured by the excessive drought, still, over all, it will come very little short of an average yield of from fifteen to thirty bushels per acre. In some instances it is spoken of as above an average, and in others as the best crop harvested for many years. While barley is spoken of as a light crop in some instances, generally it is fully an average, and in some cases considerably above. The same thing may be said of oats. All represent the yield of hay as very large, and housed, of course, in the best condition.

In the eastern and Riviere du Loup districts the reports, upon the whole, are very satisfactory. The wheat is almost uniformly spoken of favorably, though the breadth sown has not been large. Oats and barley, with some isolated exceptions, are a fair average. Hay is spoken of in a good many cases as light, while there is not so generally an unfavorable estimate of the root crops as for the west.

Upon the whole, there is every reason for the people of Ontario and Quebec being satisfied with the harvest of 1868, and thankful for it. There will evidently be enough for home consumption, and a large margin for exportation. Of course the expectations of our unusual yield raised at the beginning of the season have not been realized, but the fears subsequently entertained and expressed by many, have also, in a great degree, turned out to be groundless. With the prices going, farmers will make out well, and even though a lower price should rule for the rest of the season, they will have no reason to complain. It is a good while since such a crop of fall wheat was gathered, and though other crops may not be correspondingly bountiful, yet, upon the whole, they seem to be tolerably fair, nay, what in other years might have been looked upon as deserving of being spoken of in even stronger and more favorable terms.

Quebec Agricultural and Industrial Exhibition.

BY Legislative enactment the Provincial Exhibition of Lower Canada should be held every other year, alternately in Quebec and Montreal. The last was held in 1865, in the latter city, and consequently Quebec should have had one last year; but failing to provide the requisite funds, lost the honour. Montreal, therefore, with commendable spirit and enterprise, held one this year in place of that which should have been held in 1867. The combined Agricultural and Industrial Exhibition was formally opened on Tuesday Sept. 15th, by the Lieutenant-Governor, Sir Narcisse F. Belleau, the previous day having been occupied in receiving articles and completing arrangements. The weather during the first two days of the week was magnificent, and everything betokened a successful exhibition. The total number of entries was over fifteen hundred, and in some of the departments the show eclipsed any former one in the Province. On Tuesday there was no great crowd of visitors, but on Wednesday, spite of a most unpropitious morning, there was a very full attendance of spectators, sufficient to show that considerable public interest was felt on the occasion, though there was not the overwhelming crowding which usually distinguishes the principal public days of Western Provincial Exhibitions, rendering the task of inspection one of no small difficulty. In the early part of the day ample space was left for a leisurely examination, though a drenching rain and consequent muddy ground made it uncomfortable enough; but the sky cleared as the day advanced, and the weather, probably, did not much affect the throng of visitors. In the absence of proper show grounds and buildings, the exhibition was held in different parts of the city. The live stock and farm implements occupied a field known as the Priest's Farm, in the north-western part of the city. This field is surrounded by open sheds, and others have been erected in the middle, an open space being left for a horse ring and for implements. The agricultural productions were shown along with the industrial department in the Exhibition Building, St. Catharine Street; while the Horticultural Society held a separate show of fruit and flowers in the Drill Shed.

One noteworthy feature about this Quebec exhibition which strikes a stranger from the Western Province, and would doubtless be still more surprising to an American visitor, was the comparative absence of side shows. A few refreshment stalls were to be seen along the route to the fair ground; but beside these there were not many temporary erections to be seen outside; indeed, one vociferous and eloquent showman nearly opposite the principal entrance seemed to be without any rivalry in his line, and doubtless realized a rich harvest from the credulous public by the exhibition of "Dr. Livingstone's Chimpanzee" and the "living Kodloo-kamba, from the wilds of South Africa." This last animal, to judge from the pictorial representation on the outside, was a slight improvement on the Chimpanzee, and suggested the idea of Barnum's gorilla. Both the city and the exhibition proper gain by the paucity of these itinerant caterers of the marvellous.

In the live stock department there was altogether an excellent show; and though the accommodation was of a temporary nature and adapted for fine weather only, yet the general arrangements were good. Following the order of the prize list, the animals were grouped according to their classes and sections, so that a fair opportunity was given both for judges and spectators to make their comparisons between animals of the same breed and age. Up to the time of our leaving the ground, however, the visitor had to submit to one serious disadvantage, which is especially felt in attempting to give any account of the exhibition, namely, that no names were attached to any of the articles; nor, with few exceptions, had any of the prize cards been put in their places. This last deficiency was in due time remedied; but the names of the exhibitors of animals that did not gain prizes were only in a few cases made known to the public, so that a stranger could not well specify either animals or exhibitors. This must be taken into account, and all allowance made for omissions in this cursory notice to give honour where honour is due.

With this explanation, we will speak first of the horses, of which there was a good display. A most unfortunate accident diminished the number of those on the ground on the third day. For want of proper stable accommodation, most of these animals were removed for the night, and a fire having broken out in one of the stables in the neighbourhood where some of them were accommodated, three very fine horses perished. One of these was the imported Clydesdale horse "Briton," belonging to the Beauharnois Agricultural Society. Another valuable Clydesdale, two years old, imported this year by the Huntingdon Society, and an Anglo-Norman horse belonging to the same society, were also victims of this sad catastrophe. The origin of the fire was not made known. Some of the animals in the same stable were fortunately saved.

One peculiar feature in this class was the Percheron horses, of which there were some magnificent specimens. These recently introduced heavy draught horses seem to be gaining favour in the Eastern Province, and also in the United States. They have valuable points about them which will probably lead to their introduction into Ontario.

Of the Clydesdales there were some fine specimens; among them a splendid animal called "Lord Clyde," bred by Mr. Miller, of Markham; also one imported by Mr. Robt. Brodie, of North Georgetown, County of Chateauguay, who purchased him last year from Messrs. Muir, of Huntingdon Mains, Scotland. The weight of this animal is 1,833 lbs; his height, seventeen hands and an inch. He is a well developed, finely proportioned, and powerful animal. There are other very good horses of the same breed; but the chief of all the draught horses, and indeed the best in the class, was undoubtedly Mr. Cochrane's Suffolk "Bounce," which not only gained the first prize in this section, but also the Prince of Wales' prize for the best imported stallion. This noble animal has already been described and his portrait given in the CANADA FARMER. He is now in excellent condition. Mr. Cochrane also showed a pair of Suffolk mares, in the heavy draught section—one of them imported last year and the other recently.

Among the thorough-bred horses were two beautiful animals; one owned by Mr. Carlos Pierce, of Standstead, and called "Canwell," was imported in 1863, by the Quebec Agricultural Society; the other is the property of Mr. Hugh Brodie, and is named "Wagram." He was bred in Kentucky. There was an excellent display of native Canadian horses. Altogether the show in this class was well filled, and if space permitted, many others of great merit might be specified.

The show of cattle was chiefly remarkable for the shorthorns exhibited by Mr. Cochrane, which would have graced any exhibition in the world. Most of these have made their appearance in Canadian show yards before, but some are recent importations. Mr. Cochrane did not, however, show the chief of his recent acquisitions, the Durham heifer, "Duchess 97," for which the very high price of one thousand guineas was given to her late owner, Captain Gunter, of Westerley, in Yorkshire. She was sold on the express condition that she was not to return to England. She is to be bred, we understand, to "Eleventh Duke of Thorndale," and if her enterprising owner is fortunate, will doubtless add some noble animals to the Canadian Herd Book. Mr. Cochrane also bought from Captain Gunter, for one hundred guineas, a roan heifer, "Wharfdale Rose," by "Third Duke of Wharfdale," from "Oxford Rose," by "Sixth Duke of Oxford." This heifer gained the first prize in the year old class. It is almost needless to say that Mr. Cochrane carried off all the honours in the Durham class, "Rosedale" being the most admired of the beautiful herd of these choice cattle which he exhibited. He showed also some fine Herefords, "Compton Lad" among them. A number of these choice animals were exhibited at Hamilton, and are referred to in our account of our own Provincial Exhibition, any further notice of them here is superfluous. Near these were some beautiful little creatures, a herd of Jersey cattle imported by Mr. Sheldon Stevens. They were procured mostly from the Queen's Farm at Windsor, and the rest from Mr. Fowler, of Jersey. They were genuine Alderney breed, and were now for the first time, we believe, shown in Canada. They are diminutive, gentle animals, with a deer-like expression, and well adapted for private dairies, the extreme richness of their milk making them especially valuable for the purpose. They will have to be carefully housed during our severe winters. Mr. Sheldon's herd consists of twelve head altogether, eight of which were exhibited. Close to these, and as if purposly to show to advantage the contrast in size, was a mammoth ox, "General Grant," exhibited by Mr. Carlos Pierce, of Stanstead;

his weight is said to be over 4,500 lbs., and he stands over six feet high. He looks a very Goliath among beeves. There was a pretty good show of Ayrshires, Mr. Irving, of Logan's Farm, exhibiting some good cows, and the Beauharnois Society a fine bull. Of Halloways, besides two or three bulls, there was a small herd purchased by their present owner, Mr. Ashworth, of Ottawa, from Colonel Denison. The grade cattle were numerous, and some of considerable merit.

The show of sheep was also good, and in this class Mr. Cochrane was the principal exhibitor. He showed Cotswold, Oxford Downs, and Leicesters. In the latter breed there was some good competition. Mr. D. Elliott showed a flock of Cheviots.

The collection of swine was not very large, but there were some good specimens, among them some Prince Albert pigs imported by Mr. Sheldon Stevens from the Windsor Farm. Mr. Irving also showed some good large breed hogs.

In the poultry class, Mr. Sheldon Stevens and Mr. Cochrane were the most meritorious exhibitors; but the display was very limited, and shown to great disadvantage, on account of insufficient space and utter disregard of methodical arrangement; rabbits, turkeys, bantams, geese, pigeons and Brahmas being promiscuously grouped together in the strangest confusion.

The display of implements was good but not extensive. Mr. Glenn showed a combined reaper and mower from the Joseph Hall works, Oshawa; Mr. Evans, of Montreal, an American machine; Mr. Moody, of Terrebonne, an Eagle mower; and Messrs. Frost & Wood, of Smith's Falls, a buckeye machine; Mr. Johnson, of Montreal, also showed a combined reaper and mower. There were a number of threshing machines on the ground, all to western eyes of small size, and mowed by the incline tread power with two horses. These were tested for the satisfaction of the judges on the ground, and attracted a large crowd of spectators. Ploughs, chiefly of iron, were numerous, as were also most of the ordinary farm implements. A very useful contrivance was shown by Mr. Ferguson, called a stone lifter, which seemed well adapted for the work of lifting and removing large stones, and could be applied to the purpose of raising stumps out of the ground. In the midst of this display of implements was an ingeniously contrived camp tent, which would rejoice the heart of an amateur hunter or surveyor in the back woods. It is made of good stout canvas, and most luxuriously fitted up inside with table, bed, camp stools, small cook stove, besides an ample supply of tinware, spoons, knives and forks, and all the requisites for camp life. The tent and its miscellaneous furniture can be compactly folded together, and stowed for importation in four strong bags, the whole not weighing over eighty pounds. The maker is James A. Hunt, of Quebec.

On the same open space with the implements were some specimens of fences and gates, Mr. Lewis, of Melbourne, exhibiting his newly patented contrivance that dispenses with hinges and substitutes rollers on which the gate slides. Mr. Lewis had these gates in several varieties.

On this portion of the ground was a stand of beehives, most of them made, in part at least, of straw, and also a stock of Italian bees, but the names were not attached, and there was no one near to give any explanation.

The agricultural productions were collected together in a very small compartment of the Crystal Palace or Exhibition Building. Along with some very inferior specimens, good samples were exhibited of grain and of roots, especially of potatoes, which would seem to do well in the neighbourhood of Montreal in spite of the drought. Really excellent specimens of Indian corn were also to be seen; but the show in this respect was very limited, and altogether eclipsed by the miscellaneous display of the Industrial Department, which occupied the main portion of the floor and galleries in the spacious building. Indeed, this unpretending but most important part of the Exhibition seemed so much thrust aside that a visitor might pass through the building without discovering it. There was a fair show of dairy products.

The Agricultural Department of the Exhibition was altogether creditable, and an improvement, we believe, on any former show of the Province. The total number of entries was as follows:—Horses, 225; cattle, 430; sheep, 400; swine, 127; poultry, 130; grain and seed, 177; roots and vegetables, 205; dairy products, 160; implements, 200.

At a meeting of the Agricultural Association, Mr. Cochrane was elected President, and a gold medal was awarded to him for his eminent services in importing valuable stock into the country. The society granted the sum of $100 to the Agricultural Associations of Huntingdon and Beauharnois for each of the horses lately destroyed by fire. It was also resolved to ask the corporation to contribute to the erection of permanent buildings for the accommodation of stock, &c.

The Industrial Department was held in the Exhibition Building, in St. Catharine Street, and was crowded with articles of Canadian manufacture in bewildering variety. Visitors, as usual, thronged all the passage-ways, rendering the task of progression or examination difficult and tedious.

The press of other matter more immediately within the scope of this journal precludes the possibility of any detailed description of this department.

The Montreal Horticultural Society held their show, unconnected with the Provincial Association, in the Drill Shed, a spacious, lofty, and well lighted building, admirably adapted for the purpose. The style of decoration was in good taste, and the whole effect was charming. The display of fruit was not large, but the grapes grown under glass were remarkably fine. There was also an excellent collection of apples, and some good pears and well ripened melons of luscious flavour. Of other fruit there was but a meagre show. Two long tables of flowers gave good evidence of the skill and taste of the amateur and professional horticulturists in Montreal. There was an extensive collection of stove plants, which formed a conspicuous feature in the exhibition. There was a large attendance of visitors, and during a portion of each day the strains of a good military band enlivened the scene.

The combined attractions of these exhibitions, the Dominion Rifle Match, the Anglican Synod, the visit of the Governor General and other matters of special interest, filled the city to overflowing, and it was with the greatest difficulty that the influx of strangers could find accommodation.

Montreal Verterinary School.

We direct attention to the advertisement of the Montreal Veterinary College and Institution, that is we believe steadily progressing, and doing important service to the cause of agriculture in Quebec. We may mention, in connection with this subject, that the school has lately secured a valuable acquisition in a set of life-size and magnified models, which are intended also as a nucleus of an Industrial Museum. We are informed that some time ago, Dr. Leclerc, the Secretary of the Board of Agriculture, having visited the Agricultural museums of Washington and Albany, made a report of some artificial, anatomical and vegetable models he had seen in those collections. The report was made in March last, and in consequence the Board voted $1,000 towards the formation of a similar collection. Dr. Auzoux, of Paris, was accordingly written to, and some very interesting preparations have lately arrived, which were exhibited at the recent Provincial Show in Montreal. The most remarkable of these is a horse, nearly life size, which takes into about a thousand pieces, the exterior showing on one side the skin removed, with the nerves beneath, and on the other side the muscles, each portion being coloured to exactly resemble life. The head can be removed, and divides into numerous pieces, showing all the internal portions. Parts of the back and side being removed, all the organs are displayed, being exactly modelled after life. This is intended for the use of the Montreal Veterinary School, under the able direction of Mr. McEachran, and will certainly be of the greatest benefit to the pupils, during lectures, in that excellent institution. Among the other models are jaws of thirty pieces, showing how age is discovered by the teeth. There is also a set of small models, or *tableaux*, illustrative of the structure and development of the teeth. Also, the jaws of an ox in thirteen pieces. Not the least ingenious are the pathological preparations, in thirteen pieces, showing diseases of the extremities. By the substitution of one piece for another, the same limb, in a healthy and diseased state, may be shown; bones of the hind leg twelve pieces; hind extremity dissected, showing bog spavin, wind-galls, bursal enlargement. A model of the hoof, taken into three pieces. The lower anterior extremity, showing tendons, blood vessels, nerves and ligaments. Among the vegetable preparations, is an enlarged model of a sweet pea, taking into twelve pieces, showing their minute structure and component parts; also a grain of wheat, three hundred times its natural size, dividing it into longitudinal and transverse sections, showing formation and disposition of cells, and also illustrating growth and development of germ. There is also a large egg, one hundred and forty-eight times the natural size, showing shell, lining membrane, disposition of the yolk, white, and embryotic development of chick. The Board of Agriculture also contemplate getting a large collection of model seeds and grains, belonging to various quarters of the globe, from the celebrated French firm of Vilmourin and Andrin of Paris, the whole with a view to the formation of an Agricultural Museum.

Stock Sales.

Cotswold and Southdown Sheep.—Among the advertisements in our present issue are notices of several important stock sales. Mr. Stone, of Moreton Lodge, Guelph, announces a sale of Cotswold and Southdown sheep to take place on Thursday, Oct. 15th. He offers a number of rams and ewes of both breeds, on advantageous terms, time being allowed for payment. The high reputation of Mr. Stone's flocks renders anything beyond the announcement of the sale unnecessary. Those who are commencing to raise sheep, or who wish to improve their stock, should avail themselves of this rare opportunity. A number of Berkshire hogs are included in the sale.

Short Horn Cattle.—A sale of Short Horn cattle is advertised to come off on the farm of Mr. Douglas, Onondaga, on the same day.

Short Horn Bulls.—Mr. H. G. White, of South Framminghsm, Middlesex county, Mass., U. S., advertises for sale the Short Horn Bull Ninth Duke of Thorndale (of Duchess blood). His dam is from the same cow that dropped the Eleventh Duke of Thorndale, now the property of Mr. Cochrane. The Glenvale Society also offer a Durham Bull for sale.

Prize List.—We defer, as heretofore, the publication of the Prize List till it has been officially corrected and completed.

Inter-Provincial Fruit Growers' Prize.—We insert in the present issue an advertisement, which we regret we did not receive sooner. Though dated from Wolfville, on the 30th August, it did not reach this office till after the publication of our last issue, and we fear the announcement is altogether too late to be of any use to the fruit growers of Ontario. All that can now be done is to insert the advertisement, and call attention to the liberal intentions of the Nova Scotia Fruit Growers' Association, who offer a prize consisting of a gold medal and one hundred dollars in money, for the best collection of apples, six of each sort, grown in any Province of the Dominion, to be competed for at the Agricultural and Industrial Exhibition which will open in Halifax on the fifth day of October. If the Horticulturists of Nova Scotia can beat the display of apples at the recent Exhibition in Hamilton, they may reckon themselves the champions of the world, and we should like to see the Show.

Agricultural Intelligence.

Address of the President of the Provincial Association.

At three o'clock on Thursday afternoon of the exhibition week, the President of the Association, Mr. Thomas Stock, of Waterdown, delivered the annual address from the grand stand in the Exhibition Grounds.

Hon Asa A. Burnham, of Cobourg, Vice-President of the Board of Agriculture, introduced the President to the meeting; and he then delivered his address. He was not, he said, going to make a set speech on the occasion; he made no pretensions to oratory. But he felt that he might, perhaps, in the course of a few remarks, be able to throw out some ideas of value; and if he succeeded in doing so, he would be well repaid for any trouble he had taken in the matter. He desired to bring before them a few circumstances coming under his own observation, and indicate what in his opinion would be improvements. This Agricultural Association had been in existence now for twenty-two years, and they all know that immense progress had been made in that time. He had the privilege of attending the first Exhibition in Toronto. It was one got up by a few of the pioneers of the West, some of whom were standing before him. To these men the public were now indebted for all the good which the institution they had founded had been the means of effecting. It was commenced under many disadvantages. The implements then used in agriculture were of the rudest nature, and agriculture was altogether in a most imperfect state. The time to be spared from the labour of farm clearing was too little to leave hope of much progress at that period. But what had been accomplished since then was patent to all. Year by year these exhibitions had gone on increasing in magnitude and usefulness, until they had reached their present magnificent dimensions. He sincerely hoped that in respect to them a retrograde movement would never be witnessed, but that they would ever be found to flourish. He need scarcely remind them of the immense increase which had taken place in the value of stock within the period he had alluded to. But, as a practical farmer, he would urge them not to rest contented with the stand-point they had attained, but persevere in the road of progress. The present Exhibition undoubtedly was a great success—perhaps the most successful one ever held in the Province. But he would caution them against entertaining the notion that the limit of progress had been reached, and that they had done all that was necessary. Such a notion must infallibly tend to their harm, and he would again caution them against it. It was said to be more difficult to make progress in a state of prosperity than in adversity, and his own experience led him to believe this. What should be the aim of every visitor to the fair was to increase his knowledge. Let them take with them to their homes the information so fully acquired here—let them exercise their judgment in regard to what was to be seen, and wherever they got a useful hint carry it away with them. Let this exhibition not be made by visitors a mere holiday matter—a time of pleasure and excitement. It should, on the contrary, be one of the hardest working weeks in the year to all desirous of increasing their stock of knowledge and advancing in prosperity. This seemed to him to be the great object of this exhibition, and as one of themselves he solicited them to make good use of the information which can be so fully acquired at these exhibitions. Reverting to the early days of the exhibition, he remembered that the first year all that was offered in prizes was £400. This year the Association had a prize list of $13,000. That was pretty fair progress, and furnished an answer to those who sometimes said the progress was not fast enough. It seemed to him that, looking at the advance in the time mentioned, in arts, agriculture, mechanics and manufactures, the progress had been as fast as could be safely made, and was certainly more than could have been anticipated. Mechanics, for instance, might well be proud of their contributions to the Fair; for they were such as have not been surpassed by any exhibition. Gentlemen from the States, England, Scotland, and elsewhere, who had attended the exhibition, had expressed themselves astounded at the perfection and excellence of the manufactures shown. What a contrast these fine farming implements shown presented to those in use in the time when they were confined to some old Ancaster ploughs and a few imported from Rochester—when farmers were obliged to use an article with no lever-age in the world, and when farming was altogether a tremendous task. At any of the exhibitions now were to be seen splendid iron ploughs, harvesters, and an immense variety of agricultural implements. There had in fact been a complete revolution in agriculture since those olden days. The system of sowing wheat from year to year, until even the best soils became exhausted, had given place to that of a rotation of crops, and there was no fear of a return to the old style again in that particular. And in this connection he would remark that much of the stuff raised by farmers under the new system was not such as could be exported; and since that was the case, he would say by all means encourage manufacturers to come to the Province, stay there, and be consumers. He did not believe in the rule laid down by some to buy in the cheapest and sell in the dearest market. There were circumstances when this would not be politic, and he thought that as mechanics purchased their surplus and non-exportable stuff from farmers, and thereby gave the latter a market they needed, so, in turn, mechanics should be encouraged and protected against foreigners. In the infancy of their manufacturing interests, such guardianship and encouragement was, no doubt, necessary, and then, of course, when they attained maturity they could get along on free trade principles. Protection was needed, he took it, until their manufactures reached more strength, and was decidedly the best policy for Canada at present. These were his views on the subject.

A continuous run of prosperity had increased their

institution to one of mammoth extent, so that it was not possible for all to have that opportunity of examining the articles which was desirable. The crowd was too great, and the time too short to admit of this being done. But the institution was now coming into existence under the new Act, which entirely altered their duties. He did not know what plan to suggest to remedy the evil alluded to, but was of opinion that it might be met either by an extension of the fair time, or by some other plan. Under the new Act the country was divided into twelve electoral divisions, and instead of voting at the annual meeting on some names submitted, each County Association elects at its annual meeting a representative to the Board of Agriculture. Before this, the Board and President managed all the business of the Association except during the week of the show. Then it was the President's business to take charge of the arrangements. Now the arrangements were improved, and the people had more control of the Association and its affairs. Having alluded to the vast improvement shown in all the departments of late years, he urged those present to forward the interests of the Association in every way, and not be ready to take offence at every little thing that occurred not to their liking. If they had fault to find, the way to do was not to grumble and stop at home, but come up and endeavor through their representatives to secure the desired remedy. There were too many grumblers and too few workers in that as in other institutions. But, notwithstanding all that, the Exhibition had been a great success—even beyond what could have been anticipated. Having noticed his lengthy connection with the institution, thanked them for the trust they had reposed in him, and the honor done him, by electing him President, he went on to say that he was going to retire from office, but still would always esteem it a pleasure to do what he could to advance the interests of the Association. He then alluded to the cattle disease, and to the trip of a committee of the Association to enquire into it. As one of that committee, he would say that it was admitted on all hands that the original cause of the disease is not known, nor is it known how it is communicated. He would merely say, as it was possible that some of their neighbors from the other side of the line might be present, he desired to return them hearty thanks for their kindness and hospitality to the committee, and the help afforded them in their mission. In conclusion, he would ask those present to join with him in returning thanks to an All-wise Providence for their late abundant harvest—a harvest, one of the greatest proofs of the richness of which was shown in the success of their Exhibition. He desired, finally, to return thanks to his colleagues for their co-operation, and to the local committees.

Annual Meeting of the Provincial Agricultural Association.

The annual meeting of the Provincial Agricultural Association was held in the Court-house, Hamilton, on Thursday evening, Sept. 25th. The President, Mr. J. Stock, occupied the chair. There were present a large number of delegates from the different agricultural associations. The President explained that, under the new law, the society could do no more than appoint auditors and choose the next place of meeting. Col. Johnson, London, and T. D. Harris, Toronto, were appointed auditors. On motion of Mr. Ashford, seconded by the Hon. Mr. Skead, it was resolved that the next exhibition be held at London. The Mayor of London and Ald. Partridge and Durand offered the usual guarantees of accommodation for the exhibition. Hon. Mr. Skead notified delegates that the city of Ottawa would move to have the exhibition held there the year after next. The old by-laws were re-enacted and a committee appointed to revise them. Thanks were passed to the city of Hamilton for its accommodation for exhibition purposes.

Some discussion then ensued with reference to the cattle disease. Col. Denison explained that the Hon. Mr. Allan was delegated officially from New York, and came to Canada to show that they on the other side were anxious to act with us in the matter. He had met the board in an informal manner, but had been obliged to leave Hamilton before this regular meeting of the association. It was finally resolved in reference to this matter That the Board of Agriculture be empowered to take such steps as are necessary to meet the delegates at Rochester with reference to the cattle disease, and the propriety of holding an international convention.

In answer to an enquiry, the Secretary stated that the report of the committee on the cattle disease was being printed, and would be distributed shortly.

A vote of thanks was passed to the railway and steamboat companies, the judges and the President, when the meeting adjourned.

Meeting of the Board of Agriculture.

The members of the Board of Agriculture met at Hamilton on Wednesday, Sept. 24, for the purpose chiefly of considering what steps it was desirable to take in reference to the cattle disease, and whether any relaxation could now be safely made in the order prohibiting the importation of Western cattle.

It was resolved—"That the Board having ascertained that the cattle disease has almost if not entirely abated in the Western States, and that no danger need be apprehended from the transportation of American cattle through Canada, would recommend that the Government do remove the prohibitory order on and after the 1st of October, and would, as a matter of precaution, suggest that competent persons be appointed at Detroit and Port Huron for thirty days, to inspect all cattle before being shipped through Canada, and to see that the railway companies use proper disinfectants; and that the Secretary do forthwith send a copy of this resolution to the Minister of Customs."

It was also resolved to ask permission from the Government to allow Mr. Cochrane to exhibit at Rochester.

Entries in the Agricultural Department of the Exhibition.

We give below a summary of the number of entries in the Agricultural Department of the Exhibition, and in corresponding columns those of 1866 and 1867:

	Toronto, 1866.	Kingston, 1867.	Hamilton, 1868.

The Horticultural Products at the Exhibition.

THE Horticultural Products were shown in a long wooden building erected on the west side of the Crystal Palace. This arrangement tended greatly to relieve the throng in the main building. A wide table extended down the centre, on which were displayed the fruits and flowers, and on each side of the building the vegetables, grain and dairy products were shown. Notwithstanding the very dry and unfavourable season, the collection of fruits shown was superior to those exhibited at any former exhibition, and in open air grapes especially a very marked improvement was discernible. From the crush of people always in the vicinity of the place where they are to be seen, there is no doubt a very great interest taken in them by the public generally. Among the newer varieties were shown, Iona, Israeli, Allen's Hybrid, Adirondac, Rogers' Hybrids of various numbers, and a variety of seedlings.

The division of the prize list into professional and amateur departments three years ago, has proved satisfactory, and now affords a better opportunity of showing the progress among both sections of exhibitors. It also affords either the opportunity of more correctly judging of the advancement of the other, thus making the race more decided and the parties more conspicuous than if both were mixed in one class for competition. The entries by professionals were much larger than ever before, and the same remark applies equally to amateurs. A gentleman from Ohio remarked in regard to the show, that the sight of the tables repaid him for all his trouble. Both are progressing equally fast, and indicate that Canada is destined to be a very great fruit producing country. Among the professionals, a fine display from Messrs. Geo. Leslie & Son, of the Toronto Nurseries, occupied the head of the table, where it attained just prominence from its variety and perfection. It contained 110 varieties of apples, fifty-five of pears, thirteen of plums, thirteen of hot-house grapes, and fifteen of open air grapes, besides crab-apples, cherries, currants, strawberries, and a varied collection of other fruits. A collection of the same size has never before been brought together, and has well earned the prize which Mr. Geo. Leslie, the senior in the firm, has gained for the last fifteen years. It was awarded a diploma in addition to the prize. Messrs. John A. Bruce & Co., Hamilton, also competed in this department, but fell far short of Messrs. Leslie in number, though some of the specimens were very creditable. They gained a second prize. As a whole, apples were somewhat smaller in size than those shown in 1866, which was a favourable year for their production, but fully up to those shown at Kingston last year.

Messrs. Leslie & Son made a large number of entries in apples, as did also Messrs. Bruce & Co., of Hamilton, and Wolverton & Smith of Grimsby.

Pears were shown in considerable numbers and great excellence; a collection of fifty varieties, by Messrs. Leslie & Son, taking first prize, and a collection by Messrs. Bruce & Co. coming in for a second. A very fine collection of open air grapes shown by Mr. Beadle, of St. Catharines, were awarded a first premium—Mr. Read, (of Port Dalhousie) taking second rank. Among those shown by the latter gentleman was noticeable a very large bunch of black Hamburgus, raised in the open air, which took the prize as the best and heaviest one bunch black Hamburgh grapes, although they were brought into competition with grapes grown under glass. Mr. Beadle also took first prizes for the best three bunches of black and of coloured grapes.

In hot house grapes very meritorious collections were exhibited by Mr. John Gray, of Toronto, Messrs. Bruce & Co., of Hamilton, and Leslie & Son, who all gained prizes in various sections of this fruit.

In the amateur department the most noticeable feature was the display of out-door grapes, which occupied a large portion of the tables set apart for the various fruits. Mr. Kilborn, of Clinton, took the largest number of first prizes.

Mr. Taylor, of St. Catharines, was also very successful. In his collection were to be found a large number of the newest varieties.

The kinds which were exhibited in the greatest perfection were Iona, Allen's Hybrid, Delaware and Adirondac. Pears were not shown in as large quantities as in some former years, but were of fine quality. Apples occupied the largest place on the tables, and were a show in themselves. H. J. Brown, of Niagara, had a fine twenty varieties, which took a first prize. The other entries of this standard fruit were too numerous to particularize.

Plums were shown in small quantities, and were only of medium merit. This is no doubt attributable to the lateness of the season.

Peaches were in considerable number, and mostly from the Niagara district, which is a favoured locality for the growing of this fruit. In this section Mr. H. J. Brown carried off the largest number of first prizes.

Melons were shown in considerable quantity, and some of the specimens were of enormous size and good quality.

In domestic wines made from the grape, an extraordinary progress was discernable, there being in the several sections of dry, sparkling and sweet wines, no less than 50 entries. For dry wine, Mr. James Brown had the first prize, a distinction which, considering he is only an amateur, and competed with his new-made wines against skilled professionals who showed old wines, does him great credit. The second prize for dry wine was awarded to Mr. Bauer, of Hamilton, who also obtained the first premium for sweet wine. This gentleman's sweet wine received the highest encomiums from the Judges, none of the other samples approaching it in quality. He manufactures largely for sale. For sparkling wine Mr. James Taylor, of St. Catharines, took first prize, and Mr. H. Bauer second. The judges recommend that in future the prizes for wine should be divided into two classes, namely, professional (or those who manufacture for sale) and amateur (or those who make only in a small way.)

The show of Garden Vegetables was on the whole no way behind any previous one. Here, as heretofore, the exhibition was largely indebted to W. Burgess, W. Benham, of Guelph; Walls, of Kingston; Guthrey, of Toronto; A. W. Taylor, of Hamilton; Baker, and Allen, of Guelph; and other well known exhibitors. There were monstrous heads of cabbage that had defied the drought, tomatoes in abundance, and in short every variety of garden produce in this class.

The display of *Plants in flower* was rather meagre, though being arranged in the middle of the centre table they added greatly to the appearance of the place. The paucity of their numbers may be accounted for by the great difficulty experienced in sending them to the exhibition from a distance (all those shown were from the neighborhood of Hamilton) and by the unwillingness of owners to risk removal of valuable plants from the congenial atmosphere of a greenhouse to the chilly and unsuitable air which must needs pertain to any exhibition building at this time of year.

For the best collection of green-house plants in flower, not less than twelve specimens, Mr. J. Brown, of Hamilton, has first prize, and E. Townsend, do., second prize.

For the best display of plants in flower, distinct from other entries, the above named gentlemen retain the same rank—Mr. R. Rowe, of Hamilton, coming in for a third prize.

The show of cut-flowers was not nearly so large as at former exhibitions, though the past dry season may have had a great deal to do with it. Some very creditable entries were, however, made, amongst the most noticeable of which may be mentioned a collection of Dahlias—twelve standard Dahlias and twelve Bouquet Dahlias by Geo. Leslie and Son, Toronto nurseries, each entry of which gained a first prize; a collection of Gladioli by J. A. Bruce & Co., of Hamilton, which were very much admired, and received a first prize; a collection of Asters by M. Flanagan, Kingston; a collection of perennial flowers by Messrs. Leslie & Son, some of the varieties in which were imported from Great Britain last spring, and which were of fine form and color; a collection of Hybrid Perpetual Roses by the same; and a collection of Verbenas by J. W. Sinclair, Hamilton, all of which gained the distinction of a first prize.

Fruit Growers' Association of Ontario.

The first annual meeting of the above Association, as organized under the new Agricultural Act, was held on Tuesday evening, the 22nd Sept., at the Court House, Hamilton. Contrary to what might have been expected, the attendance was but small, not more than sixty or seventy persons being present. The President, W. H. Mills, Esq., being absent through illness, the chair was taken by J. C. Rykert, M. P., Vice-President.

The minutes of the last meeting having been read, D. W. Beadle, Esq., Secretary and Treasurer, stated on behalf of the directors that there had not been time to put the report into presentable shape, as it would consist of returns from the fruit committees, and from a number of gentlemen resident in the various parts of the Province, and who are employed in fruit-growing. A report would, in due time, be prepared, and submitted to the Minister of Agriculture, when it would be given to the public. Four essays had been sent in on "the cultivation of the apple," and the committee appointed to adjudicate the prizes had awarded the first to the one bearing the motto, "The price of good fruit is eternal vigilance," Mr. W. Beadle, author, and the second to one from the pen of Mr. J. T. Duncan, of Bayfield. At the request of the meeting, Mr. Beadle then read his essay, which was greeted at the close with appreciative cheering. The Secretary-Treasurer then reported the state of the finances as follows:—

Balance on hand at last report		$ 21 28
Members' fees		157 00
Government grant		350 00
		$528 28
Paid stationery and printing	$43 78	
Travelling expenses of Fruit Committees	29 25	73 03
		$455 25

The annual address of the President was then read by Rev. R. Burnet. It gave an interesting *resumé* of the history of the Association since its organization in 1859, described its present legal basis and sphere of action, as defined by the New Agricultural Bill, referred to the amount of the Government grant, and urged the desirableness of its being increased, from the numerous ways in which it might be usefully expended, among which the importance of Entomological investigation to abate insect ravages upon fruit was named, and closed by pointing out various directions in which the Association might render itself of signal service in promoting the fruit-growing interest.

The election of officers was then proceeded with. Mr. W. H. Mills was re-appointed President, and Mr. J. C. Rykert was re-appointed Vice-President. Mr. D. W. Beadle was again elected Secretary and Treasurer. The following gentlemen were chosen Directors:—

His Honor Judge Logie, Hamilton, G. Leslie, Toronto, John B. Martin, Cayuga, C. Arnold, Paris, Rev. R. Burnet, Hamilton, A. M. Smith, Grimsby, J. Springer, Barton, George Muston, Guelph, W. Saunders, London.

Miscellaneous business was then in order, and a number of practical matters were discussed, the chief among them being the best methods of destroying certain insect depredators, and the necessity of more stringent measures being adopted to prevent robbery of orchards and gardens and spoilation of shade trees. On the latter subject it was resolved that the President and Secretary petition the Dominion Legislature, in the name of the Association, for the insertion of clauses in the forthcoming Consolidation Act, conferring summary powers on magistrates for the punishment of such offenders. A vote of thanks to T. Swinyard, Esq., General Manager G.W.R., for reduction of fares to members attending the meetings of the Association, closed the proceedings of the evening, and the meeting adjourned.

The next meeting will be held at St. Catharines, on Tuesday, the 13th day of October, 1868, in the Town Hall, commencing at 11 o'clock, a.m., to continue through the day and evening. The Directors will meet on the 14th. By arrangement with the Great Western Railway Co., members attending the meeting at St. Catharines will receive a certificate that will enable them to return at one-quarter fare.

In another issue we hope to give, in full, the President's Address, the Prize Essay, by Mr. Beadle, and other interesting documents for which we have not space in the present number.

Apple Trees Killed by Frost.

To the Editor of THE CANADA FARMER:

SIR,—According to promise, I now send you a list of my apple tree losses from the severity of last winter. The trees were planted two years ago last spring, and had done exceedingly well. Indeed, I had not previously lost a tree.

It will be easily seen which are the tender and which the hardy varieties. A few would have died from bark splitting, but at the same time they are blighted and dead. The following list shows the different varieties that were winter-killed:

261	trees	R. I. Greening,	frost-killed	49
151	"	Baldwin	"	95
140	"	King of Tomkins Co.	"	86
75	"	Ribston	"	28
25	"	Bellflower	"	14
50	"	Roxbury Russet	"	0
20	"	Fall Pippin	"	7
20	"	Twenty-ounce	"	4
10	"	Red Astrachan	"	0
10	"	Early Harvest	"	0
5	"	St. Lawrence	"	0
5	"	Kentish Filbasket	"	2
25	"	Spitzenberg	"	0
50	"	Colvert	split	2
50	"	Golden Russet	"	2
45	"	Fameuse	"	8
942				297

More than the above list are damaged; those given are beyond recovery. A correspondent in a late number of the CANADA FARMER wrote favourably of King of Tomkins County as the apple for Canada. They have stood the worst of all with me, and a friend remarked to me a day ago that he had lost every one of his King of Tomkins County apples. Older trees of same varieties have stood better.

Last winter was about the coldest known in this region. The following are the registered degrees at and below zero: Dec. 12th — 5°; 13th — 4°; 14th — 16°; 19th — 12°. January 12th, 0; 17th—8°; 22nd, 0; at noon — 2°; 27th — 13°; 28th—4°. Feb. 3rd — 20°; 7th — 12°; 8th — 3°; 11th — 14°; 14th — 16°; 17th — 8°; 22nd — 12°; 29th, 0. March 2nd — 2°, — 5° at noon; 3rd—28°; 4th — 14°; 5th, 0. Only twice at noon did the thermometer fall below zero. To this extreme cold and sudden great changes of temperature do I ascribe the loss of so many of my trees.

I have no doubt, if the trees had been older and more set in their growth, but little damage might have been done. I see all of the varieties growing by different individuals, from twelve to sixteen years planted, with little damage. There are none of King of Tomkins County of that age yet. J. McL.

New Mode of Destroying Wasps.

WASPS have been rather plentiful. I have for several years adopted a very simple, but very effectual, plan of getting rid of their nests. When I find a nest, I select the noon of a hot sunny day for my operations. I procure a very strong solution of cyanide of potassium, and I saturate a piece of lint, about three or four inches square, with the solution. This lint I quietly place at the outlet of the hole leading to the nest on the ground, in a bank, or elsewhere. Nothing more is requisite. Every wasp that arrives at the hole on its descent alights on the lint, and, after one or two gyrations, drops over the edge of the lint into the hole, dead, or else dies upon the lint—not one escapes. After sitting down by the side, watching the operation for about ten or fifteen minutes at most, the number of wasps arriving home becomes very much lessened, and then only a few odd ones arrive. I then dig out the nest. All are destroyed. There is no fuss, no risk of being stung, as every wasp coming home falls on the fatal lint, and has no escape. The evaporation of the cyanide is very rapid, and the air all around the hole is tainted, and the wasps seem fascinated by it, as I never see any turn away; they look as if they must settle, and when once they alight they have no power to raise themselves, the use of the wings is gone, and they are soon dead from the inhalation of the cyanide. This is a very simple way of destroying the nest, because if you do not wish to take the nest, you may leave the lint there; it will destroy all the nest, and will do no harm to anything else.

When the nest is in a tree, I generally go in the evening, and hold the lint soaked in the cyanide under the bottom hole. The wasps soon begin to drop out, first one by one, then in a regular shower. Of course caution must be used to avoid the inhalation of the cyanide, but as so little is required, it is not very probable any accident will result from the proceeding.—*Cor. in Journal of Horticulture*

Entomology.

The Apple Worm.

TO THE DIRECTORS OF THE FRUIT GROWERS' ASSOCIATION OF ONTARIO.

THE apple crop this year will be a very short one. This is due in large measure to the depredations of the apple worm, which is the caterpillar of a pretty little moth named "*Carpocapsa pomonella*," an insect, alas! far too familiar to the orchadist in its larva or caterpillar state, though but seldom seen in its perfected condition. Anything relating to this pest will at this season be deemed interesting, and while we may not advance much that is actually new, it is well where so much is at stake to be reminded from time to time of facts partially or wholly forgotten.

I believe all authorities agree that this insect passes the winter in its chrysalis, or inactive state, generally lodged in the crevices in the bark of trees, or in some other secure retreat. From the middle to the end of June the moths make their appearance, concealing themselves during the day, flying only at night. Late in June and early in July, they pair, and soon after deposit their eggs. Usually one egg only is attached to the eye, or blossom, end of the fruit, but occasionally they are fastened about the base of the stalk, for I have several times when cutting into fallen fruit found the worm which had eaten into the apple from this point. Mr. Walsh, State Entomologist for Illinois, has found two in a single apple, one of which entered at the eye, the other at the stem. I found this year what I believe to be a similar example, though the worms had left. Besides the usual channel from the eye to the core, there was in this instance another from the stem in the same direction, and there were two holes through which the castings of the worms had been pushed, one about half an inch from the stem—the other on the side of the fruit. In this instance the whole of the seeds had been consumed, and a large portion of the apple.

Mr. Walsh has also found specimens which had been attached to the cheek of the apple, and made their entrance from that point, but these are all exceptional cases.

In a few days the egg is hatched, and the worm at once begins to burrow into the fruit, making its way towards the core, pushing its castings, which appear like a brownish powder, through the orifice by which it has entered. When it reaches the centre of the fruit it devours more or less of the seeds, and after a while eats a channel through the side of the apple, at the orifice of which its castings and refuse are now thrust out, and through which the caterpillar, when full grown, makes its escape.

In about three or four weeks it comes to maturity, and is then a little more than half an inch long, of a pale reddish or flesh colour, with a small reddish brown, horny looking head, and a patch of the same color and appearance on the upper part of the first segment or ring behind the head. There are also a few faint brown dots, and fine short hairs on each ring, but these can scarcely be seen without a magnifying glass. It has six hook-like feet, and five pairs of fleshy legs, by which it can readily be distinguished from the grub of a curculio, or any beetle, these latter being furnished with only the six hook-like feet. It also spins a silken thread, by which it can let itself gently down from any height.

In some instances the worm leaves the fruit before it has fallen, but in most cases I believe they do not make their exit until after the apple has dropped; it is not, however, then long delayed. Here is a matter that should be noted, for if the apples are to be gathered with a view of destroying the worms, a daily visit should be made to the orchard for this purpose, for it is labor lost to gather the fruit after the grubs have left. The worm usually finds its way to the nearest tree, oftentimes to the tree from which it has dropped, where having lodged in some obscure retreat, it envelops itself in a thin, whitish, silken cocoon.

Within the cocoon is the chrysalis, which is of a reddish brown colour, with two rows of small spines on each of the middle segments, and one row on the hinder ones. By means of these spines it works its way through the cocoon before the moth escapes.

The moth, when its wings are expanded, will measure nearly three quarters of an inch. Its fore wings are dark grey, streaked across with brown, with a large patch of brown on the end of each wing, tapering towards the tip, and having a horse-shoe mark of a metallic or satin lustre in its centre. The hind wings are pale reddish brown, with a satin-like lustre.

There has been some uncertainty among American entomologists as to whether there are one or two broods of this insect during the summer. In Europe, from whence the moth is derived, it has long been regarded as double-brooded, and of late Mr. Walsh has shown that such is the case in this country, at least in his locality, Illinois. My own experience leads to a similar conclusion. I have this year reared the moth early in August from fruit gathered late in July, and have found young specimens of the worm again quite late in August. Mr. Walsh has observed that as a rule the first brood attack the early apples, while the second brood infest chiefly the later ones.

We come now to the practical bearing of these remarks, and enquire what remedies have been proposed and tested to check the ravages of this little pest? One method recommended, and which has already been referred to, is very good as far as it goes—it is to gather the fallen fruit and destroy the grub by dipping it in boiling water; or turn pigs into the orchard to eat the fruit as it falls. But this does not reach the worms which had left the fruit before it dropped, and there are doubtless many other specimens that escape by making their exit almost immediately after the fruit reaches the ground. The remedy proposed to reach these, and which originated with Dr. Trimble, of New Jersey, consists of hay ropes wound round the trunks of the trees, two on each tree, one two or three feet higher than the other. This acts as a decoy, affording them retirement and shelter; they make it their hiding place in which to spin their cocoons. By carefully examining these ropes every few days during the season large numbers of the culprits may be secured, in both worm and chrysalis state, and their ranks terribly decimated. It is stated that as many as a thousand have been taken in a season, in this manner, from one tree, and where it has been thoroughly tried along with the first method referred to, good crops have invariably resulted. Pieces of old cloth and various other fabrics have been used in place of the hay ropes with very good results. Complete extermination can hardly be looked for, since with the best of management a few will probably escape; but let the fruit grower do his duty, and with the help of birds and insects who prey upon these and similar creatures, there need be little fear of their depredations becoming formidable.

The same insect affects the pear, and destroys large quantities of this valuable fruit every year; the remedies are the same as in the case of the apple.

There is another species of grub destructive to the apple, but I am not aware that it has ever yet been found in Canada, although it has proved very troublesome in Massachusetts, Connecticut and New York. It is called the apple maggot, and is the larva of a two-winged fly, named by Mr. Walsh *Trypeta pomonella*. It is very different in appearance and habits from the common apple worm. It is a greenish white, footless grub; there are often six or more in an apple, and they do not burrow into the core, but eat channels through the flesh of the fruit. Should this insect make its appearance in any part of Canada I should like to receive specimens of it.

W. SAUNDERS.

Hair Snakes.

WE have received a rather long communication from "Zebra," accompanied by a bottle containing a lively specimen of a parasitic worm commonly called a Hair-snake (*Gordius Aquaticus*), together with an intertwined mass of its thread-like young. As we have already noticed this singular animal in the CANADA FARMER for Jan. 15, 1868, page 28—to which we refer our correspondent—and as our columns are at present much crowded with other matters, we are obliged to dismiss this subject very briefly, and omit "Zebra's" interesting account of the birth and proceedings of this strange little family. He will find his specimens awaiting him at our office, but if he does not care to preserve them himself, we should like to add them to our own collection of alcoholic specimens. We may mention that the specimen we received from Mr. Arnold lived for upwards of six months in a bottle, the water being changed at long intervals.

CECROPIA CATERPILLAR.—J. H., of North Keppel, lately sent us a specimen of this fine insect well packed in a tin box, and with some of its appropriate food—the way in which we like to receive all our specimens. He found it on an apple tree, and was naturally much struck with its size and beauty; on its way to us it spun up in the box and formed its large silken cocoon. He will find a notice of it in our last number, page 278.

Poultry Yard.

Poultry at the Provincial Exhibition.

The arrangements made for the poultry department were far in advance of the accommodation provided at any former Provincial Show, the pens being admirably arranged under a covered shed, enclosed by open battens, with doors at each end and one side. This enabled the judges to make their examination without being interrupted by visitors. As regards the coops, they would have been better not quite so deep from back to front, and with a step or some means for a proper inspection of the upper tier.

We were glad to see the Dorking classes in the ascendant, some chickens especially of this variety being very fine. Messrs. Peters, Bogue and Rykert had some excellent specimens, and gained prizes.

Polands and Hamburgs were not quite so well represented, and there can be no doubt that some importation of fresh blood from the old country is very necessary. Some fine white chicken Polands were shown by Mr. Bogue, of London; but, unfortunately, being entered in the class for adults, they were excluded from a prize.

In Buff Cochins the absence of the remarkably fine display that graced the last Exhibition in Toronto, and has been quite a feature in the Shows of the Poultry Association, was very noticeable. The dispersion of Col. Hassard's birds greatly reduced the Hamilton Show in this class, though some of them in other hands, or the progeny of his stock, made themselves known in the recent Exhibition. Some young birds were shown by Mr. Roach, of Hamilton, and among them the most beautiful colored pullet we have ever seen. The cockerel shown with her was equally meritorious, and for stock purposes they could not be better matched; but for exhibition, as the colors did not agree, they had to surrender the first prize to Mr. Rykert, who also obtained the same for adults, all very fine birds. White Cochins were not represented.

In the Light Brahma class there were some handsome pullets. Mr. Rykert had some very good birds of this variety. The Dark Brahmas were not represented at all.

French varieties were not forthcoming.

The Sebright Bantams were few, but good samples, although we should prefer them smaller. All the best birds in this class were shown by W. & J. Peters, of London. There were some good chickens of this variety. Other varieties of bantams deserve no special mention. The black were the best, but deficient.

We were disappointed in the specimens of Game birds, which were far behind those of the last exhibition in Toronto. Exhibitors in this class would do well to be more careful in matching the birds correctly, and seeing that the legs of both birds agree in color, as a want of correspondence in this respect is at once a disqualification.

We now have to mention the Spanish class, which we think a most meritorious one; such hens as those exhibited by Mr. Hincks (of Toronto), have, we opine, never been seen in Canada before. Some persons even expressed the opinion that their faces were enamelled or painted. It is to be regretted that an accident happened which prevented a pair being shown in the second pen exhibited by that gentleman; but the single hen was highly commended—and we think the judges might have placed a "very" before it. Other exhibitors showed good specimens, but all should in this class take knowledge of what Spanish fowls' faces should be.

Mr. Rykert, (St. Catharines), and Mr. Barnes, (St. Thomas) gained second and third prizes for very fine birds.

Some fowls of doubtful purity were shown in the adult "any variety" class; but in the chickens some good Leghorns were shown by Mr. Rykert, and in the extra some good Dominiques by Mr. Herning, of Waterdown.

All the common Turkeys were good; but the wild were not up to the standard in any way. We hear that some dissatisfaction manifested itself respecting the amount of the awards in this class. We must say we agree with the awards of the judges, the only approach to the real wild turkey of Western Canada being in the pen for which the second premium was awarded. The first prize was withheld. The other pairs in the Wild Turkey class should have been entered in class 20, when they would have been in their right places. We hope shortly to give the points of the wild Turkey, very carefully prepared by Col. Hassard, with some remarks by that close observer and enthusiastic poultry fancier, on the variations caused by the accidental mixture of wild and domestic birds.

Geese were few but good, especially those shown by Mr. Cullis, of Hamilton, and Mr. Barnes, of St. Thomas.

Aylesbury ducks were below the standard.

The Rouens were very few but very good. Those exhibited by Mr. Peters well deserved the prizes awarded for them. Other kinds were also good.

Some Guinea and Pea fowls were shown in fair condition for the time of year, and deserved their awards, but the pens were sadly too small for the large birds.

In pigeons there were few exhibitors, and the specimens deserved no special commendation.

We regret to see that the Rabbits were passed over without any premiums. We think this could hardly have been otherwise, as even in the common sorts better marked and sized animals should have been exhibited to obtain premiums.

The Judges in this class were Col. Hassard, Messrs. A. M. Howard, Miller, Finch, and Van Ingen, and they evidently acted upon what we believe to be a a new rule (39 in the prize list), and abstained from awarding premiums to the best of a bad lot. Granting prizes at all events, even for most unworthy specimens, because no better were shown, has been too much the custom at Provincial Shows; but when we look at the object of these exhibitions, which is the improvement of stock, &c., we cannot but think the principle a correct one, and that if specimens were not up to the mark they should only be awarded premiums according to their deserts.

We congratulate the Society on this part of the Exhibition, and we cannot but perceive that the Ontario Poultry Society's efforts to improve the breed of fowls has not been in vain. We hear that Mr. Lamb, one of the largest London exhibitors, was prevented through illness from sending his specimens. Some pens were consequently empty; had they not been this would have probably surpassed any former Provincial Show. As it is, London, in the persons of Messrs. Peters and Bogue, contributed most largely and meritoriously to the recent Exhibition.

Freak of Nature.—A Turkey, on the farm of Rotherwood, Georgina, was set to hatch eleven eggs, in order to propagate her breed, but she left her charge, and to the surprise and great interest of the family, as well as people in the neighbourhood, a *turkey cock* was seen to take possession of the nest and eggs; he sat constantly on the eggs till he hatched six poults, which he tends with parental pride.

The Household.

☞ The three best medicines in the world are warmth, abstinence and repose.

A Bright Idea.—When Jemima went to school, she was asked why the noun "bachelor" was singular? "Because," she replied, "it is so very singular that they don't get married."—*American Paper.*

Preservation of Leather.—A contributor to the *Shoe and Leather Reporter* gives some valuable hints in relation to the preservation of leather. The extreme heat to which most men and women expose boots and shoes during winter deprives leather of its vitality, rendering it liable to break and crack. Patent leather particularly is often destroyed in this manner. When leather becomes so warm as to give off the smell of leather, it is singed. Next to the singeing caused by fire heat, is the heat and dampness caused by the covering of India rubber. India rubber shoes destroy the life of leather. The practice of washing harness in warm water and with soap is very damaging. If a coat of oil is put on immediately after washing the damage is repaired. No harness is ever so soiled that a damp sponge will not remove the dirt; but, even when the sponge is applied, it is useful to add a slight coat of oil by the use of another sponge. All varnishes and all blacking containing the properties of varnish should be avoided. Ignorant and indolent hostlers are apt to use such substances on their harness as will give the most immediate effect, and these, as a general thing, are most destructive to the leather. When harness loses its lustre and turns brown, which almost any leather will do after long exposure to the air, the harness should be given a new coat of grain black. Before using this grain black, the grain surface should be thoroughly washed with potash water until all the grease is killed, and after the application of the grain black, oil and tallow should be applied to the surface. This will not only "fasten" the colour, but make the leather flexible. Harness which is grained can be cleaned with kerosene or spirits of turpentine, and no harm will result if the parts affected are washed and oiled immediately afterward. Shoe leather is generally abused. Persons know nothing or care less about the kind of material used than they do about the polish produced. Vitriol blacking is used until every particle of the oil in the leather is destroyed. To remedy this abuse the leather should be washed once a month with warm water, and when about half dry, a coat of oil and tallow should be applied, and the boots set aside for a day or two. This will renew the elasticity and life in the leather, and when thus used upper leather will seldom crack or break. When oil is applied to belting dry it does not spread uniformly, and does not incorporate itself with the fibre as when partly damped with water. The best way to oil a belt is to take it from the pulleys and immerse it in warm solution of tallow and oil. After allowing it to remain a few moments the belt should be immersed in water heated to one hundred degrees, and instantly removed. This will drive the oil and tallow all in, and at the same time properly temper the leather.

Rats.—Rats originally came from Norway, and I wish they had originally staid there.

They are about as uncalled for as a pain in the small of the back.

They can be domesticated dredful easy, that is az far as getting in cupboards and eating cheese and knawing pie is concerned.

The best way to domestikate them that I ever saw is to surround them gently with a steel trap; yon can reason with them to great advantage.

Rats are migratious—they migrate whenever they have a mind to.

Pizen is also good for rats—it softens their moral nature.

Cats hate rats, and rats hate cats, and—who don't?

I suppose there is between fifty and sixty millions of rats in America, but I quote entirely from memory—and I don't suppose there is a single necessary rat in the whole lot. This shows at a glance how many waste rats there iz.

Rats enhance in numbers faster than shoe pegs do by machinery. One pair of healthy rats is all that any man wants to start the rat business with, and in ninety dais, without any outlay, he will begin tew have rats—tew turn oph.—*Josh Billings.*

Poetry.

After.

After the shower, the tranquil sun;
After the snow, the emerald leaves,
Silver stars when the day is done;
After the harvest, golden sheaves.

After the knell, the wedding bells;
After the bud, the radiant rose;
Joyful greetings, from sad farewells
After our weeping, sweet repose.

After the burden, the blissful meed;
After the flight, the downy nest;
After the furrow, the waking seed;
After the shadowy river—rest

—*Round Table.*

Katy did.

Throughout the night I hear the cry go up toward the stars.
And the answer, in denial, seeme to beat against the bars
That lie across the gates of pearl, as surf beats on the shore,
And the night rings with a pleading I have never heard before.

For though full oft the Katy-did its bold assertion made,
And still the prompt denial rang throughout the willow glade,
To-night they seem to hold in tune the harmonies of song,
And, half forgetful of the hours, I linger late and long.

But who has known what Katy did? and when was it all done?
How long will the contention last? When was it first begun?
When David watched his father's flocks, upon the verdurous plain,
I wonder if he heard their cry with pleasure or with pain.

Or when adown the sacred Nile swept Cleopatra's barge,
I wonder if the Katy'a cry rose from the Lotos marge,
Was Cheops, as his eye surveyed the mighty Pyramid,
Still puzzled with the query as to what poor Katy did?

Since Clio's page no record shows—since Thalia's lips are sealed—
It scarce can matter to us now though it were all revealed.
Oh, Katy! whether true or false, there's one thing that I know
It all should be forgotten, since it happened long ago.

Miscellaneous.

The New London Dog Law.—A good anecdote relative to Sir Richard Mayne's law of muzzling dogs is in circulation at the clubs. An officer of the Guards went out the other day with a favourite dog with a muzzle fastened on his tail. He had not gone far before he was accosted by a policeman, who told him that as his dog was unmuzzled he should take it up and detain it. This the officer in question defied him to do, maintaining that as his dog had a muzzle on his tail he had complied with Sir Richard Mayne's order, because it was not stated where the muzzle was to be placed on the dog. This so fairly baffled "the intelligent policeman" that he at once gave way, and let the Guardsman depart in peace with his faithful companion.

THE WORLD.

"It's a very good world to live in,—
To lend, to spend, or to give in;
But to beg, or to borrow, or recover one's own,
It's the very worst world that ever was known."

So some cynical individual has written. It may be true, but it is also true that this is the best world as yet known by us. It is barely possible that the cynical souls may go further and fare worse. Let us hope not. *Ex.*

Markets.

Toronto Markets.

CANADA "FARMER" Office, Sep. 30th, 1868.

The Produce Market during the past fortnight has continued quiet; except in barley there has been little doing. The barley market has been very irregular, rising and falling in sympathy with Oswego.

FLOUR AND MEAL.

Flour.—The market has been unusually quiet; very few lots have been offering, and there has been little or no desire to buy. Some buyers will not give over $5 40; holders refuse to sell at anything less than $5 50. In the higher grades of flour there has been a few lots selling; a few 100 bbl lots of extra sold at $6 50; and of superior at $7. Fall wheat flour is scarce and finds ready sale.

Oatmeal.—Selling in small lots at $6 50.

Cornmeal.—Only a small trade doing; prices range from $4 to $4 50.

Bran.—Selling at $15 per ton.

GRAIN.

Wheat.—The market has been decidedly dull since our last report. No sales of any importance have taken place. Spring wheat has been offering rather more freely, but the demand is so limited that no sales take place. Holders ask $1 18 to $1 20 for spring, in car or cargo lots, but there are no buyers except in a few cases at over $1 16 to $1 16. The demand is only from local millers, who will only buy sufficient to supply the wants of local consumption. Fall wheat is in better demand, and sells readily in car lots at $1 35 and $1 38. Very few lots of Fall are offering. The street market is beginning to be fairly supplied. The following are the street prices which have been paid. Spring, $1 16 to $1 16. Fall white, $1 30 to $1 35.

Oats.—The market has been firm. Car lots offering sold freely at 51c. on the track. On the street market 53c. was freely paid for good samples.

Barley.—The market since our last review has been very irregular, advancing and declining alternately in sympathy with Oswego. Prices are, however, now fully 3c. to 10c. higher than they were a week ago. Yesterday the market took a start and advanced 6c. Car and cargo lots were to-day selling freely at $1 18. The sales to-day were 5,000 bushels at $1 18 f. o. b., 3,000 bushels at $1 17 f. o. b.; two cars at $1 18 f. o. b.; 7,000 bushels in car lots at $1 18 f. o. b. The market closes very firm at $1 18 f. o. b. On the street market there was a fair business doing. The receipts, however, do not come up to what is usual at this time of year. During no day last week were there over 35,000 bushels brought in by farmers, and the average receipts from farmers would not amount to over 18,000 or 20,000 bushels per day. Prices on the street kept steadier than on 'Change. To-day $1 17 to $1 18 was the price paid for ordinary samples. A few choice samples brought as high as $1 19½.

Peas.—The market has been very quiet. There were no wholesale transactions reported. On the street market 01 cents was the price.

Rye.—Only a few loads coming in from farme, s' waggons. Buyers are paying 80 cents on the street market.

HAY AND STRAW.

The market has been fairly supplied. Hay has been selling at from $12 to $16, and straw at from $7 to $10.

PROVISIONS.

The market has been very dull. Butter and cheese are the only articles in which there is any animation.

Butter.—The shipping demand is steady, without any change in price. Round lots are selling at from 20c. to 21c. Dairy, in shipping lots, would bring 22c. Very few lots offering on the market; pound rolls bring from 22c. to 25c.

Eggs.—Very few coming in; selling only in a retail way, from 12½c. to 16c.

Cheese.—Held firmly at from 12c. to 13c.

Dressed Hogs.—Receipts are now considerable; selling at from $6 50 to $7 25.

Pork.—Very little in the market.

Bacon.—Nothing doing, except in a small way.

Salt.—Liverpool has been in good demand. Lots are now worth from 80c. to 90c. on the wharf. American, in barrel, sells at $1 60 on the wharf.

Wool.—Unchanged. Selling in small lots at from 26c. to 27c.

Hops.—There is a fair supply offering. We quote—New, from good to exam. per lb., 20c. to 25c; fair to good, do. 15c. to 20c.; old, 10c. to 15c.

Flax.—Is fair demand, but very few lots offering. There are buyers at $8 to $10 per 100 lbs.

THE CATTLE MARKET.

Beeves.—The market has been well supplied with all kinds of cattle, and there has been a fair demand, especially for first-class cattle for export. We quote per 100 lbs., dressed weight: 1st class, $6 to $6 50; 2nd do., $5 to $5 50; 3rd do., $4 to $4 50.

Sheep.—Have also been offering freely, and met with a ready sale at the following figures: 1st class, $4 to $4 50 each; 2nd do., $3 to $3 50; 3rd do., $2 to $2 50.

Lambs.—There has been a fair supply on the market, and the demand has also been good. All the lots offered found ready sale at the following prices: 1st class, $2 50; 2nd do., $2; 3rd do., $1 50.

Calves.—Scarce, and not much enquired for; worth from $5 to $8.

Live Hogs.—Several lots have been offering, principally from the west. Prices ranged from 5c. to 6c. per lb.

HIDES AND SKINS, per lb.—*Hides*, green, rough, per lb., 5½c.; do. green, inspected, 7c.; do. cured and inspected, 7½c. to 8½c. *Calfskins*, green, 10c.; cured, 12c.; dry, 18c. to 20c. *Lambskins*, green, 45c. to 50c. *Sheepskins*, 60c.

London Markets, Sept. 29.—Red Fall Wheat per bushel, $1 10 to $1 19½; white wheat, $1 15 to $1 20; spring wheat, $1 10 to $1 18; barley, $1 12½ to $1 15; peas, 89c. to 90c.; oats, 42c. to 43c.; butter in rolls, 23c. to 24c.; do. in tubs or crocks, 18c. to 20c.; lard per lb. 10c. to 12½c.

Galt Markets, Sept. 29.—The market is busy. No change in wheat, but tending downwards; considerable quantities coming in. Barley, 90c. to $1 10—a very good supply coming in but quality poor. Eggs, 12c. to 13c. Butter has risen very rapidly of late, 20c. to 23c. Potatoes, 75c. to 90c. per bush. Peas and oats scarce. Oats, 45c. to 52c. Peas, 90c. to 95c. Hay, $11.

Guelph Markets, Sept. 29.—Fall Wheat, $1 20 to $1 26; spring wheat, $1 10 to $1 14; oats, 50c. to 55c.; peas, 86c. to 90c; barley, $1 00 to $1 12; wool, 26c.; hides per 100 lbs., $6; beef, do. $7 to $8; pork, per 100 lbs., 00c. straw per load, $3; hay per ton, $10 to $11; eggs, per dozen, 12c. to 13c.; butter, per lb., 20c. to 22c.; apples, per bushel, 00c.; potatoes, per bag, $1 15 to $1 50; sheep skins, 46c. to 50c.

New York Produce Market.—*Flour*—Heavy, 10c. to 15c. lower—receipts, 17,000 barrels and 024 bags; sales, 5,700 barrels, at $6 30 to $7 15 for superfine state and western; $7 65 to $8 05 for common to choice extra state; $7 15 to $8 75 for common to choice extra western. *Rye Flour*—quiet, at $6 25 to $8 10. *Wheat*—2c. to 3c. lower; receipts, 55,500 bushels; sales 45,000 bushels at $1 55 No. 3 spring. *Rye*—quiet. *Corn*—About 1c. lower; receipts, 46,000 bushels; sales, 78,000 bushels at $1 12 to $1 15½ for unsound; $1 16 to $1 17 for sound mixed western. *Barley*—scarce and firm; receipts, 9,400 bushels. *Oats*—1c. lower; receipts 83,000 bushels; sales 41,000 bushels at 72½c. to 73c. for new western. *Pork*—a shade easier at $28 32 to $28 62 for new mess; $28 37 to $28 70 for old mess. *Lard*—Heavy and drooping at 18½c. to 19½c. for steam; 12½c. to 13c. for kettle rendered.

THE CANADA FARMER is printed and published on the 1st and 15th of every month, by the GLOBE PRINTING COMPANY, at their Printing House, 26 and 28 King Street East, Toronto, Ontario, where all communications for the paper must be addressed.

☞ Subscription Price $1 per annum, (POSTAGE FREE,) payable in advance. Bound volumes for 1864, 1865, 1866 and 1867, may be had for $1 30 each. Subscribers may either begin with No. 1 of the present Volume, or with the first No. of any preceding volume. No subscriptions received for less than a year, and all commence with the first number for the respective years.

CLUBS will be furnished at the following rates:—

TEN COPIES for	NINE DOLLARS.
TWENTY COPIES for	SIXTEEN DOLLARS.
FORTY COPIES for	THIRTY DOLLARS.
ONE HUNDRED COPIES for	SEVENTY DOLLARS.

To Agricultural Societies ordering more than 125 copies, THE FARMER will be sent at SIXTY CENTS.

THE CANADA FARMER presents a first-class medium for agricultural advertisements. Terms of advertising, 20 cents per line space. Twelve lines' space equals one inch. No advertisement taken for less than ten lines' space.

Communications on Agricultural subjects are invited, addressed to "*The Editor of the Canada Farmer*," and all orders for the paper are to be sent to GEORGE BROWN,
Managing Director

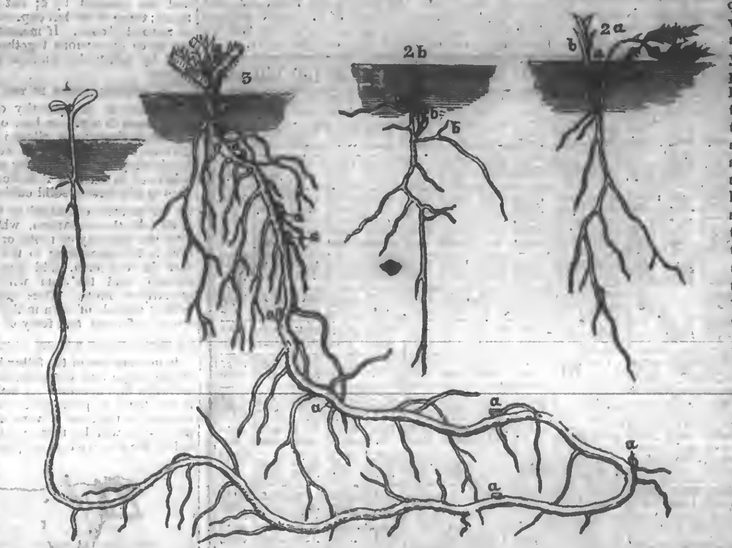
The Field.

Thistle Seedlings.

It will be seen by the following extract and accompanying illustration that an error somewhat prevalent in this country, and which has repeatedly been combatted in the CANADA FARMER, has not yet been rooted out of the old country. Our correspondent "Publicola," will be pleased to see a confirmation of the lesson he has more than once sought to inculcate on his brother farmers, in the following communication and editorial remarks from the *Agricultural Gazette*:—

"'There is a very strong opinion existing, not only here, but all over England, among many intelligent and practical men, that the common corn or wayside thistle will not grow from seed, or rather that it does not produce seed. As to myself, I am satisfied that it produces seed and that its seed will grow. Any one doubtful on that head could not do better than try the experiment at once by sowing in a flower-pot, or anything at hand, as the seeds this autumn are, I find, well ripened and numerous, and I think some fine specimens are not rare. The very hot summer has seeded abundantly Sainfoins, Lucerne, &c., besides weeds of all sorts.'

"In response to the above suggestive letter, and in reply to several similar questions recently received, we re-produce some illustrations of experiments which we made nine years ago. These were given in the *Agricultural Gazette* of Aug. 25, 1860. On the 2nd September, 1859, ten recently-gathered seeds of the common field Thistle (*Carduus Arvensis*) were sown. By the 21st, or at the end of nineteen days, all the seeds had not only come up, but advanced to the condition shown in Fig. I. After the first frost, the whole of the plants had apparently died; as spring came on, however, they were making roots and buds. Figures 2*a* and 2*b* show two stages of this progress; the buds *b b* are the growing points of the plant, by which its multiplication by secondary buds, *a a*, is brought about. Figure 3 shows how one of the plants advanced between February 27th and June 28th, the time when our last drawing was made. In this the secondary bud had grown up to a large prickly, but abortive bud, while preparation was made in the tertiary buds—*a, a, a*, in Figure 3—for a complete plantation of Thistles."



The Wheat Crops of East Lothian.

To the Editor of THE CANADA FARMER:

SIR,—In your issue of July 15 there appears an article on "British *versus* American Farming," in which there is an extract from the *Farmer* (Scottish) that says: "The East Lothian farmer, who can enjoy the pleasure and deep satisfaction of viewing the level field of full-eared wheat swaying in the undulated waves beneath a bright sun, giving to the grain a last golden tinge before the reaper enters on its clattering work, can almost to a nicety tell you that he will thrash from that field his fifty or sixty bushels an acre." Now, sir, if such is the case—if some of the East Lothian farmers can look down on such magnificent crops, there must be others of them that have to look down on wheat crops very much less—indeed, not so far ahead of the "careless agricultural sinners," to whom you direct your homily, as you would have us believe.

In 1857, the latest year in which the crop statistics were taken in Scotland, the average wheat crop of East Lothian is given at twenty-six bushels and two and a half pecks per acre. In 1856 it was given at twenty-eight bushels and three pecks per acre; which, taking the average of the two years, gives about twenty-seven and a half bushels as the average wheat crop of that county.

In reading your article one would think that most of the farmers had such magnificent crops. But let us see with the average as above how the matter stands. I believe that there are about twenty thousand acres under wheat in the county in question. Now suppose we allow seven thousand of these acres to yield say fifty-five bushels per acre—equal to three hundred and eighty-five thousand bushels—(while the whole twenty-thousand acres, at the average of twenty-seven and a half, would give five hundred and fifty thousand)—leaving the other thirteen thousand acres to yield one hundred and seventy-five thousand bushels, or about thirteen and a half bushels to the acre, so that is it easily seen how far they are ahead of the "careless agricultural sinners" of Canada.

I never was in East Lothian, but know that it is always looked upon as one of the best farmed counties in Scotland—the one indeed in which improved agriculture took its first rise in that country, and I certainly wish that their crops may never be less; but I suspect the *Farmer* was stretching them a little when he would make us believe their wheat generally yielded fifty or sixty bushels to the acre.

I can hardly agree with your own views at the close of the article, as my opinion is that the East Lothian farmers are far less subject to having their wheat crops *winter-killed* or seriously damaged by *insects*, and these I consider are about the greatest draw-back to the growth of fall wheat that the "careless agricultural sinners" in Canada have to contend with.

W. R.

Cobourg, Sept. 12, 1868.

Farm Weights and Measures.

At the request of a correspondent, we subjoin the rules for measuring various agricultural commodities in the bulk, also for measuring land, and the standard weights of the principal grains, &c. The information thus condensed may have appeared at different times in former numbers of this journal, but, as our correspondent suggests, it will be convenient for many farmers to have it collected in a convenient form for reference. With regard to some of the matters, no infallible rule can be given, and much is necessarily left to the judgment. In such cases as estimating the weight of cattle by measurement, for instance, the results are not always correct, and it is by the practised eye and experienced judgment, rather than by any arithmetical calculation, that the most successful drovers and butchers form their opinions and regulate their operations.

TO MEASURE LAND.

To find the area of a square or oblong piece of land, measure the length and breadth in rods (16½ ft.); multiply the two together, and divide the product by 160, which will give the number of acres in the lot. If the shape of the land be triangular, with one corner square, to use a common expression, proceed as above, and take one-half the product as the area of the triangle. In measuring irregular fields, divide the space into parallelograms and triangles, ascertain the area of each, and the sum of the whole will give the total area.

The following rules also embrace a large number of the cases requiring surface or land measure.

To find the area of a triangle.—Multiply the base by half the altitude, and the product will be the area. By the altitude is meant a line from one angle drawn perpendicular to the opposite side as a base.

To find the area of a parallelogram.—(A four-sided figure with opposite sides parallel.)—Multiply the base by the altitude, and the product will be the area. By the *altitude*, in this instance, is meant the perpendicular distance between any two opposite sides.

To find the area of a trapezoid.—(A four-sided figure with only two sides parallel).—Multiply half the sum of the parallel sides by the altitude, and the product is the area.

To find the area of a Trapezium.—(A four-sided figure which has no two sides parallel.)—Divide the trapezium into two triangles by a diagonal, or line drawn between two opposite angles, then find the areas of these triangles; the sum will be the area of the trapezium.

The following table, clipped from the *New England Farmer*, will be found very convenient for ascertaining the area of small square or oblong plots of land. The larger figures on the margin and diagonal, represent the measurement in feet, as taken on the ground. The area given in smaller figures is expressed in square rods by the upper number, and in acres by the lower number.

There are two tables given below, having no connection with each other, except that the darker figures in the lower are in continuation of those in the upper at corresponding intervals. In the first table the *width* of the piece of land, expressed in feet, must be looked for in the diagonal row of darker figures, the *length* in the horizontal row of darker figures at the top. In the second table the *width* must be looked for in the diagonal row of darker figures, and the *length* in the vertical column of darker figures at the left. The area will be found below the one and opposite the other.

To illustrate the use of the table:—Suppose we wish to know the contents in rods and in acres of a piece of land 140 feet long by eighty feet wide. We look in the upper table for 140 in the top row of dark figures, and find it at the top of the last column but one. Following that column down opposite to 80 in the upper diagonal row of dark figures, and we find it contains 41.14 square rods, or .2571 acres. Suppose we have another piece just twice as long and twice as wide; we look in the lower table for the length, 280 feet, in the vertical column of dark figures, and for the width, 160 feet, in the lower diagonal row, and find them at the head of the second column; then following that column down opposite 280, we find the area to be 164.55 rods, or 1.065 acres.

TABLE OF MEASURES OF LAND.

TO MEASURE HAY IN THE STACK OR MOW.

If it be a square or oblong stack, with a pitched roof, measure the height in feet from the base to the eaves, add to this half the height from the eaves to the ridge, to find the mean height; multiply the height by the breadth, and the product by the length. Divide the gross product by 27, and the quotient will be the number of cubic yards in the stack. The estimate of the total weight must depend upon the supposed weight of a cubic yard; this will necessarily vary according to the time allowed for the stack to settle. In an old stack the hay is much more compact than in one recently built. A pretty correct estimate will be gained by allowing 35lbs. to the cubic yard in the new stack, and 100lbs. in one that has stood a few months, and 112lbs. if it has stood more than a year. To ascertain the weight of hay in the stack, multiply the number of cubic yards by the number of pounds allowed, and the product will give the contents of the stack in pounds; divide by 2,000, and the quotient will give the number of tons. To ascertain the weight of hay in a round stack with a conical top, find the height to the eaves, and add one-third of the remainder to obtain the mean height of the whole. Measure the girth; square this dimension (that is, multiply it by itself), and multiply the product by the decimal ·0795. This will give the area of the base. Multiply the area by the mean height, and the product will be the contents of the stack, in cubic feet, divide by twenty-seven and we obtain the number of cubic yards. Multiply this as before, by the number of pounds allowed to the yard, and the product will give the gross weight in pounds. To estimate the contents of a mow where the top surface of the hay is level, the process is the same as with the square stack, or rick, omitting the allowance for the sloping roof.

TO MEASURE GRAIN IN THE BIN.

Multiply the length by the width, and their product by the height in inches; divide by 2,150 (the number of square inches in a bushel), and the product will give the number of bushels in the bin.

TO MEASURE CORN IN THE CRIB.

Measure the length, width, and depth of the crib in feet; multiply these three dimensions together, and the product by 4; cut off the last right hand figure: those to the left express the number of bushels of unshelled corn. If measured in inches multiply the three dimensions together, and divide the product by 4,300; the quotient will be the number of bushels.

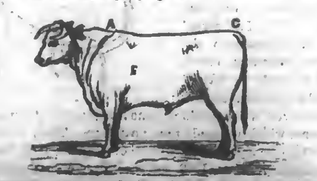
TO MEASURE ROOTS IN THE PIT OR ROOT-HOUSE.

To estimate the quantity of potatoes, turnips, or other roots in a pit, or bin, or root-house, ascertain the cubic dimensions, either in inches or feet, as in the case of small grain or corn, making allowance for the slope of the ridge by measuring only half the height, or so much of it as would be required to level the top and have a solid cubic heap:

Of the amount estimated as for small grain take three-quarters, which will give the quantity of roots; or if measured in feet according to the rule for corn in the crib, add one-half the amount, and the sum will be the quantity of roots. Thus a space that would hold twenty bushels of corn in the ear, would hold thirty bushels of roots, and forty of grain.

TO ESTIMATE THE WEIGHT OF CATTLE BY MEASUREMENT.

In making use of the following rules, the regularity of the shape and the condition of the animal must be taken into account. A deduction must be made if the flank is poor, and something over may be allowed in the case of very fat cattle. The mode prescribed will be more readily understood by the aid of the accompanying figure:



Measure, with a tape line, from the top of the shoulder *a*, to the tail head *c*, and mark this for the length; then measure round the body at *f*, immediately behind the shoulder, and mark this for the girth. Multiply the *square of the girth in inches* by the *length in inches*, and divide the product by 7,344, and the quotient is the weight in imperial stones (eight pounds). Or, square the girth in *feet*, and multiply it by the length in feet; multiply again by the decimal .238, and the sum is the weight in imperial stones.

STANDARD WEIGHTS OF THE BUSHEL.

The following table shows the standard weight of the bushel of grains and other agricultural products:

BUSHELS.	LBS.	BUSHELS.	LBS.
Wheat	60	Potatoes	60
Corn	56	Turnips	60
Rye	56	Carrots	60
Barley	48	Parsnips	60
Oats	34	Beets	60
Peas	60	Onions	60
Beans	60	Dried Apples	22
Buckwheat	48	" Peaches	33
Clover Seed	60	Malt	86
Timothy "	48	Salt	56
Blue Grass Seed	14		
Flax "	56		
Hemp "	44		

Rust in Wheat.

An elaborate report on the occurence of rust in wheat, and other diseases, has been published by a commission appointed for the purpose in Australia. In reference to this document the *Mark Lane Express* has the following notice:—

The enquiry into the nature and causes of the red rust, by the Commission appointed for the purpose by the Governor of South Australia, has elicited a vast fund of information from the collected report of eight hundred 'agriculturists,' and, although the statements are in many respects very contradictory, the committee was enabled from them to obtain general results, which, while they showed the fallacy of the opinions advanced, established the fact that no condition of soil or climate is free from its ravages, nor will any precautions taken by the farmer prevent these. "The rust-spores," says Dr. Muecke, "are located and spread over the whole world; neither oceans nor mountains will stop them. They do not commence to grow and multiply until they meet the circumstances favourable to their existence and nourishment." The following statement is given in the report as the evidence collected by a member of the Legislative Council:

The red rust is caused—	Red rust also prevails—
1. By the exhaustion of the soil.	1. On newly cultivated lands.
2. By late sowing.	2. By early sowing.
3. By manuring.	3. Manure prevented.
4. White straw is the best.	4. Purple straw is the best.

Such are the contrary opinions—doubtless all adopted from observation and experience; but only proving that other influences than those adduced have operated, and will constantly operate, to neutralize general theories on this and many other subjects of natural history; more especially those relating to endemic and epidemic disease. In either the animal or vegetable economy. There is not a doubt that climatic conditions have the greatest share in the production of the red rust. A moist, warm season causes a florid development of vegetation, and opens the breathing pores of the plant, and so gives passages to the spores of the parasites which are continually held suspended in the air. These, entering the openings thus left, throw out their rootlets (*mycelia*), and by intercepting the sap between the stem and ear, impoverish the grain and destroy the crop. Dr. Muecke is of the opinion that the red rust never attacks the wheat plant unless it is otherwise diseased—in fact, that it is *an effect* and not *a cause*, or at least, a second, rather than a first cause, being itself superinduced by the corrupted state of the juices of the plant. "Where the rust destroys," he says, we may safely infer that the plants were in a suffering state before they were attacked. Nature does not allow morbidness to exist. . . . The red rust has not destroyed our crops; it has merely furnished the eruption thereto." But, "on the other hand," he says further, "it is equally true that on vast surfaces the red rust has been the main cause of the destruction of plants in regard to the formation of the grain." A remarkable case in proof of this theory is stated in his letter. Part of a field of wheat in which wild oats had prevented the wheat from growing was cut for hay. Immediately the wheat sprung up healthy and vigorous, and developed full ears and fully grown grains; not a particle of rust was perceptible on these parts of the field, whilst the surrounding thick and high wheat was completely covered with it. The cause assigned is, that the wheat, in the one instance, did not grow till the time was past in which the influences supervened that predisposed the plants; consequently they became strong and healthy. While the red rust spores passed over them they were not infected, because the spores did not find the conditions of their existence—that is, diseased sap and weak cells—upon them. This is clear enough; because, surrounded as these mown spots must have been by the wheat on which the rust prevailed, the former could not have escaped if the same conditions had prevailed in them as in the other.

Salt for Crops.

A Subscriber sends us the following clipping from the *Glasgow Herald*, with a request that we would publish it in this journal:

"I have been reading with very great interest the account of the 'Proceedings of the Chemical Department,' given by Dr. Anderson, in the 'Transactions of the Highland Agricultural Society of Scotland' of February last, and I wish to state what that account has suggested to me. The account is devoted chiefly to field experiments, under the auspices of the Highland Society, in various districts, for determining the comparative effects of different manures in the production of turnips.

1. It appears from the account that in several plots drought delayed or prevented a general braird, so as to make the experiments unsatisfactory, and not sufficient for affording beneficial deductions. Why not endeavour to secure a braird by salting the land, and thus attracting moisture from the atmosphere? My turnips were sown this season when the land was utterly dry. The braird came quickly and without a miss, and the plants continue growing rapidly with rich glistening blades. The land, just before being drilled, was sown over with salt at the rate of good twelve cwt. per imperial acre. Years ago I commenced with four cwt., and the quantity of salt has been increased year after year, till this season it amounted to fully twelve cwt.

2. It appears further that finger-and-toe interfered with results, so as to render comparison all but valueless. Why not have it as a condition that the land should be well dressed with hot lime? I have had no finger-and-toe since I adopted this practice.

The salting of the experimental ground would ensure a braird, and the liming of it would prevent finger-and-toe; and the application of both would affect the experiments favourably, inasmuch as there would then be sound turnips to test the virtues of the several manures. But I believe that a proper quantity of salt is itself a preventive. My turnips are past the stage for finger-and-toe, and although the land has not been limed, they are not affected with the disease.

In the garden the results from "salt" and "no salt" are worthy of notice.

1. No salt. The turnips quite a failure,

2. Salt. The swedes and turnips alike excellent. Part of the turnips got a double quantity, and they are twice as forward as the others, good as these are. I may mention that, in this instance, the salt was not mixed with the soil, but scattered on the surface immediately after the seed was sown. The quantity was at the rate of about four cwt. per acre, except where the swedes are best, which got at the rate of about eight cwt.

3. In this garden hitherto there never was raised anything like a crop of carrots or leeks. The soil and not the treatment of it was blamed. It is a heavy soil. This season, when the ground was, according to the practice of former years, ready to be manured and seeded, I had it salted and dug over. Farmyard manure was then spread over it, salt scattered over the manure, and the whole dug in. Parsnip, carrot, leek, and onion seeds were then sown on several plots, and the result is that each crop is as rich as could be desired, to the astonishment of those who had long known the garden. I should state that one plot of carrot ground was not salted, and the result is that of former years—not the fourth of a crop. This has been interplanted with transplants from the swede ground, and when the transplants stand up coarse salt will be spread between the rows, care being taken not to touch the plants with salt.

I may mention that between the rows of my field cabbages salt was put on at the rate of fully twelve cwt. per imperial acre, and they are doing remarkably well; and that as soon as my potatoes were planted and covered, salt was sown across the drills at the same rate per acre. These are a fine crop, with good stems and dark glossy leaves.

When I think of the severe loss occasioned by the "worming" of oat crops, I am led to remark that my crops never suffer from this destructive plague. Salt, at the rate of four cwt. per acre, is broadcast immediately after the sowing of the oat seed, and harrowed in; or if that has not been done on account of rain, and if "worming" appear, salt is applied without delay to the "worming" parts, and the "worming" at once ceases, but the crop is generally better on these parts than on the rest of the field where salt had not been sown."

A Large Yield.

To the Editor of The Canada Farmer:

Sir,—Thinking it might not be uninteresting to your agricultural readers to know something of the crops their fellow-farmers are raising, I send you the subjoined account of the quantity produced this harvest and last, from a single field situated on Lot 33, 2nd Range, in the township of Pickering.

From this field, containing 11 acres, I raised, this year, 560 bushels 45 lbs of barley,—lacking only 3 lbs. of making an average of 51 bushels per acre, —some 480 bushels of which were sold to Mr. Whiteside, of Frenchman's Bay, at 96½ cents per bushel, the remainder being kept for seed for the ensuing year, and other purposes. But taking the whole quantity at this price, and the entire value of the crop nets $541 30. The quality of the grain may best be estimated from the fact that 46½ lbs. was the average weight of each bushel by measurement.

The same field was under spring wheat last year, and produced 385 bushels, or an average of 35 bushels per acre. The price realized was $1 63 per bushel, and consequently the whole crop was worth $627 55.

We often hear it said that farming in Canada does not pay, and that people in Canada had better not invest their money in real estate, as the return realized from the crops scarcely rewards the husbandman for the labour of tilling and reaping; but $1,168 85 ought surely to be enough to pay well for the cultivation of 11 acres for two years, and still leave a large margin of "clear gain," much larger, in your correspondent's humble opinion, than can be obtained from any other investment equally safe.

WILLIAM COWAN.

Improvement of Worn-out Lands with Grass and Clover.

A correspondent of the *New York Times* writes to that paper as follows:

I will tell my experience on a poor farm in Rhode Island, of 150 acres, and too poor to keep a yoke of oxen, one cow and one horse in good condition. This farm was worth at that time about $4,000 or $5,000. But a new man came along who thought he could raise grass where none grew before. He tried, with perfect success every time; so that in a few years he kept about fifty head of cattle, mostly cows, on the place, and sold annually as many tons of hay.

The *modus operandi* was this:

1. Plough the land.
2. Harrow.
3. Spread 200 bushels ashes per acre.
4. Harrow.
5. Sow millet and clover.
6. Harrow.
7. Roll.
8. Cut half ton of millet to the acre in six weeks from sowing time, enough to pay expenses first year.

He then had a good stand of clover, which was cut twice the two years. The next year he ploughed under the clover, harrowed, applied fifty bushels ashes to the acre, harrowed it in, again sowed millet and clover, harrowed and gave it a good rolling. In six weeks he had a good growth of millet, say two tons per acre, and another good stand of clover. The next year he cut two crops of clover again. The next year he turned under the clover, applied his barn-yard compost of muck and cow manure, which he had been four years preparing, and raised eighty bushels shelled corn per acre, on land that, before he commenced, was called barren, and land that the neighbours said, when he was applying the ashes, was not worth, ashes and all, after it was mixed, what the ashes cost.

Now, there are a great many inquiries about how to raise clover. This man never failed; he never thought of it, and never dreamed of it, and never knew any failure. He had a system in his head (for he did not get it from books) which he carried out like "clock work," and his farm was beautiful to look at. He said the land was not fit for manure, so he took four years to get it ready.

He thought ashes would produce millet and clover, and millet would protect the young clover from the scorching sun until it would need no protection.

The harrowing and rolling were indispensable. He commenced in May, and sowed millet and clover every day as fast as the land was ready, for two or three months, and knew no such word as fail.

Stock Department.

Digestion.

All the functions of the living body are most intimately connected with each other, and the relations they mutually bear must be borne in mind, in order fully to understand any one of them. This reciprocal dependence is clearly manifest in those vital processes that have already been briefly described in former numbers of this journal—in those, namely, of the circulation of the blood, the breathing, and the temperature of the body. Closely related to these is the important function of digestion—which comes next under consideration. This is the prime agent in supplying the waste of the system, resulting from those constant and active changes that are going on in all living bodies during the continuance of life.

By digestion is meant not merely the process that is carried on within the stomach, but all the series of operations by which the crude material taken as food becomes gradually converted into blood,—the fluid that is more immediately concerned in repairing the loss and disintegration of the tissues. We will first give a brief summary of the various stages in this process, and afterwards consider them in detail.

In the first place, then, the food is taken into the mouth, and more or less divided and crushed by mastication. This preliminary operation is more requisite in some cases than in others; accordingly we observe considerable and well-marked diversities in the apparatus employed, corresponding to the nature of the food, and the wants of the animal. Indeed the exact adaptation of the teeth to the peculiarities of various animals is so well defined and constant, as to afford the readiest and most reliable index to their general habits and structure, and has become, therefore, an important basis in all systems of zoology, for the classification of animals. The food, after being subjected to the action of the teeth and of certain secretions in the mouth, passes into the stomach, where it is acted on by a powerful solvent—the gastric juice—and is softened and partially dissolved, so as to be reduced to a pulpy mass, which receives the name of *chyme*. In some vegetable feeders, the food, before being submitted to the action of the gastric juice in the stomach proper, is returned to the mouth and re-masticated—a process familiarly known as chewing the cud. Next, the chyme passes into the intestines, where it is further acted on by various secretions, is more completely dissolved, the indigestible and effete matters separated, and the nutritive and soluble portion at length reduced to a milky fluid, which receives the name of *chyle*. This is taken up from the intestines by certain absorbent tubes, called, from the colour and character of their contents, *lacteal* vessels. The chyle bears a close resemblance to blood, in many particulars, and may be regarded as the last stage in the conversion of crude food into that fluid. The intestinal tube varies greatly in length in different animals, being longer or shorter according as the food more or less approximates to animal tissues. For example, it is shortest of all in those who live on the blood of other animals, and longest in those who feed on grasses and vegetable materials, the nutritive elements of which are least concentrated. It is comparatively short in exclusively carniverous creatures, and of medium length in those whose diet is of a mixed nature, as in man.

The consideration of the first process of mastication, including the structure, growth, and peculiarities of the teeth, a subject of much interest and importance, as it will require the aid of illustrations, and would extend this paper to inconvenient length, must be deferred to the next article in this physiological series.

Sheep Farming in Turkey.

The British consul at Adrianople gives some interesting details of the sheep and goat farming in that vilayet. He gives the number of sheep at 4,512,000, and of goats at 778,000, the tax on which, at the rate of four piastres each, yielded £171,297 in 1867. Nevertheless it is estimated that 20 per cent. profit is obtained by sheep husbandry. The tax produced £10,596 more in the year 1867 than in the previous year, and for the last ten years there appears to have been a steady increase in the number of sheep. The peculiarity of the shepherd's work in this district is the process of milking the sheep and the goats, large quantities of butter and cheese being made from the milk of these animals and sent into Constantinople, whence also the sheep and lambs are sent from the district or vilayet of Adrianople for local consumption. The total cost of a flock consisting of 1,800 ewes, 150 rams and 50 goats, is stated to be 90,500 piastres, the cost of keep, &c., being 31,000 piastres, and the total value of produce, exclusive of the skins, 56,910 piastres—112 piastres being equal to the £1 sterling. There is an active market for the skins of the lambs and goats, which are salted and packed for the French and English market.

The two prominent breeds, which are considered by the natives as distinctly local, are the Kavirjik, which bear some affinity to the demi-Merinos, and the Karabash, which are black-faced, and not unlike the sheep in Macedonia and Thessaly. The wool of the former is most esteemed, being long, soft, and elastic, and twisted in ringlets, which gives the name to the breed.—*London Field.*

Feeding Trough.

We copy from the *American Agriculturist* the following description and the above cut of a convenient feeding trough for hogs and sheep.

Sheep and hogs will put their feet into the troughs if they can. They will even stand and lie in them, and defile them in every possible way. This may be prevented by various means, but we think that no one has suggested a simpler remedy than Mr. Jacob Nixon, of Van Buren Co., Iowa, who sends us a sketch and description of an appliance he has put upon his troughs, which is seen in the accompanying engraving. Neither hog nor sheep can feed from such a trough with both fore feet in at once, and it would be difficult for any but a very young animal to stand or lie in the trough. The improvement consists of a board set up edgewise, lengthwise over the middle of the trough, kept in place by standards at the ends, and a brace, if necessary, in the middle. The trough, *H*, is represented as ten inches high and twenty inches wide; the standards, *I I*, are inch boards, four inches wide, and the board, *J*, over the trough is of inch stuff, eight inches wide. If the trough is more than ten feet long, a brace, *K*, is needed; otherwise not. This contrivance is equally applicable to log (dug out) or plank troughs.

The filthy condition which pig troughs especially are often allowed to attain, must be injurious to the appetite even of a hog, and will affect the health and economical fattening of the animals to a more serious extent than is generally supposed.

To Manage a Rearing Horse.

Whenever you perceive a horse's inclination to rear, separate your reins and prepare for him. The instant he is about to rise, slacken one hand, and bend or twist his head with the other, keeping your hands low. This bending compels him to move a hind leg, and of necessity, brings his fore-feet down. Instantly twist him completely round, two or three times, which will confuse him very much, and completely throw him off his guard. The moment you have finished twisting him round, place his head in the direction you wish to proceed, apply the spurs, and he will not fail to go forwards. If the situation be convenient, press him into a gallop, and apply the whip two or three times severely. The horse will not, perhaps, be quite satisfied with the defeat, but may feel disposed to try again for the mastery. Should this be the case, you have only to repeat the discipline.—*Ex.*

Acclimation in Australia.

By a late number of the *Australasian*, a weekly paper of general information, and which consists of thirty-two pages of closely printed matter, it appears that English sparrows are now thoroughly established near Melbourne, and have assumed all their English habits, breeding rapidly, tearing the thatch of roofs and ricks into holes, and generally making themselves obnoxious; their good deeds in destroying insects to supply the calls of their broods, are not prominently seen; whereas their fruit-robbing, seed-destroying, bud-picking, and general sins of commission, are patent to all. The inhabitants speak of removing protection from them. If they are like English sparrows they can protect themselves.

It having been found by some speculative members of the Acclimation Society that an ostrich in full health and condition would yield feathers to the value of twenty-five pounds annually, the society state that they have fenced in a "paddock" 111 of ten thousand acres, and imported a flock of ostriches which are doing well.

The English hare is now thoroughly established near Melbourne,—they breed often, and produce two and three (oftenest three) at a birth.

Rabbits introduced, and wild, now swarm in many parts of the province. They seem to do wonderfully well.

English Pheasants do not seem to succeed, or at all events they have not done as well as many other birds. Chinese pheasants and the various kinds of partridges are now well established and increasing fast. Sky larks are now plenty around Melbourne, having been introduced.

Black Hamburgh, Chasselas, and all our greenhouse grapes, come to splendid perfection in the open air, and without shelter, in Australia.

Fowls in the Horse Stable.—Fowls should never be permitted to have access to the horse stable, nor the feed room, nor the hay mow. Their roost should be entirely separate from the stable, so that they may not always be ready to slip in whenever a door is opened, and that the vermin which infest poultry may not reach horses and cattle. It is a well known fact that fowls of all kinds frequently drop a very sordid, offensive, clammy, viscous odor, and when allowed to go on the hay mow, or in the feeding room, or anywhere in the barn, they damage more fodder than we are wont to suppose. We would as soon allow fowls to live in the kitchen, and hop on the dinner table while we are eating, and to roost on the bedstead, as to allow them to have free access to the horse stable and barn. Some horses are always afraid of fowls, and when one enters the manger, or rack, the timid horses will immediately surrender their entire right, however hungry they might be, to these lawless marauders.

Veterinary Department.

The Drugging of Farm Horses.

All descriptions of horses are apt to suffer from the ignorance, prejudice, and quackery of their attendants. Farm horses have certainly more healthful surroundings than their town brethren; they are seldom subjected to the fast pace which tells so severely on the lighter description of horses; their feeding and labour are usually tolerably regular; but much of their ill-health results from the mismanagement and the meddling medical treatment of the attendants.

Ploughmen and carters in many parts of Scotland are, unfortunately, following the evil example of their English brethren in giving the animals under their charge frequent doses of various sorts of medicine. It is poured down in season and out of season; whether the horse is well or ailing; without any knowledge either of the state of the animal's health, or of the effects of the nostrum; and without the owner's being at all aware that his horses are thus ignorantly tampered with. It is sad to think of the rubbish which the poor horse is thus compelled to swallow. Amongst the favourite articles exhibited are dragon's blood, black antimony, sulphur—and the blacker it is the more it is thought of—spices and condiments of all kinds, and innumerable unsavoury concoctions of things animate and inanimate, hurtful and harmless. In some parts of England, and especially in the southern and western counties, the horse keepers collect various herbs, and cunningly preserve them by drying, salting, boiling, or other processes. Thus prepared, these medicaments are used either regularly with the notion of improving condition, or at rarer intervals as a means of curing particular disorders. These preparations of herbs are seldom, however, very potent or hurtful. But carters and farm servants also use strong mineral poisons. In many of the provincial towns the chemists retail enormous quantities of these noxious articles. The mineral acids, preparation of antimony, arsenic, and mercury, are commonly used, or, we ought rather to say, abused. The infatuated mortals have such blind faith in the efficacy of their nostrum, that they will purchase it regularly, even with their own hard-earned money. A scrupulous chemist often demurs about supplying dangerous poisons which he well knows are to be given without the master's knowlege to his valuable horses, and given too by ignorant and often unskilful hands; but the man is not to be diverted from his purpose, and usually has little difficulty in finding a less particular or more complaisant physic monger. Indeed, the physic is, we know, occasionally obtained in barter for grain, hay, straw, or roots, or for a cart or two of coals or other commodities surreptitiously drawn for the drug merchant.

A case illustrating the danger of horses being drugged by their attendants recently came under our observation. On a large farm where sixteen horses were worked several were reported "out of sorts." One had died several days before, after about a week's illness, and with symptoms and *post mortem* appearances which pointed to gastric derangement. Three more horses were unable to eat, and were daily losing flesh; they were slightly feverish, and the digestive organs somewhat out of order, but there was no evidence of cold nor of any acute ailment. The food had consisted of clover and grass, with a few split beans. The stabling was commodious and comfortable. No admission could be got that any medicine or anything besides the ordinary food had been given. The cases appeared puzzling. A careful examination discovered that the back teeth were blackened, and in places softened and decayed; the throat was sore; the stomach irritable. It was evident that the horses had recently been having some corrosive substance. On suspicion of giving such noxious matters, the principal carter was at once discharged. His fellow-workmen's tongues were soon unloosed, and it appeared that anxious to get his horses eat and thrive, the fellow had been in the habit of giving them their corn and chaff wetted with spirit of salt or hydrochloric acid. Weeks elapsed, and demulcents, weak alkalies, and other remedies were freely used; but still the horses remained in a low, thriftless state, from which they only very slowly recovered.

Cases such as these are more numerous and frequent than are generally supposed. When a change of horse-keepers occurs, how often do we find a whole lot of horses fall away in condition, and lose all spirit and endurance, no matter what food they receive. In such cases, if the truth can be got at, it will generally be found that the waygoing fellow has for months, and perhaps for years, been giving acids and other drugs, and that under such tonics, condition-medicines, or pick-'em-ups, the horses looked and worked very fairly. The evil of the system only comes out with all its force when the unnatural drugging is stopped. None but professional men should, under any pretence, prescribe poisons or any potent medicines. The handling of edged tools is a dangerous pastime to those unused to such weapons. Untrained practitioners, if they will dabble in physic, should confine themselves to simples and harmless medicaments, which, even if used ignorantly or carelessly, can do little detriment. No sensible horse proprietor should permit any servant, whether he be groom, coachman, ploughman, or carter, to give on his own responsibility any sort of physic to any horse. By such a dictum peremptorily enforced, he will prevent much sickness and loss; he will have no horses dying, as we have repeatedly known them, from balls given surreptitiously sticking in the windpipe, or from injuries of the fauces inflicted by the sharp weapons on which the balls are often administered. He will not have his horses dying from superpurgation, or dangerously reduced by depressing remedies, or shelved for a few days because their attendant has in his wisdom conceived that they will be better of "a little physic." Many and ingenious are the excuses often advanced in favour of this time-honoured practice of giving medicine to horses: the animal is too fat or too poor, he has been on soft or on hard food; he is going to or returning from the country; he is the better of a good dose of medicine in spring, or summer, or in autumn, or, as we also often hear sagely stated, "he wants the London dust got out of him!" With suitable food, properly regulated exercise or labour, roomy stables, and good grooming, horses can be kept in admirable condition and health without much medicine.—*North British Agriculturist.*

Open Synovial Cavities.

The primary cause of these fearful accidents is the pride of mankind; gentility is always striving to impose upon credulity. It loves to be mistaken for something better than it really is. After all, this vice of society is nothing more than the child's game of "Lords and Ladies," played by grown up persons. A horse having a naturally defective neck is obtained; no barbarity is too abhorrent to repress the hope of making people believe the steed, thus deformed, is a creature of extremest value. The animal, if ridden, has the chin pulled in close to the neck; if driven, the free carriage of the body is prevented by the cruel bearing-rein. The horse progresses in agony, while gentility sits smiling at the result of its artifice. The horse cannot see the ground before it, because of the constraint imposed upon the head; it cannot fix attention upon its duty, because of the agony which the cunning of gentility inflicts upon the lips. The pace is always rapid; the action is high, as in the case of blindness; and the animal, generally, comes to earth with violence. The skin upon the knees is divided, and the structures beneath are penetrated. One or more synovial sheaths are opened, while the cavities, formed by the junction of the separate bones, may be lacerated.

Sheath or joint may not be immediately opened by the fall, but either may have their integrity destroyed, through the slough, induced by the contusion consequent upon a broken knee. Moreover, various accidents will occasionally happen—misfortune is of infinite variety. The synovial bursæ, sheaths or cavities of the hind legs, are occasionally punctured by the quadruped kicking violently, while in harness. The capsule, embracing the tendon of the flexor brachii, upon the point of the shoulder, has been opened by the animal drawing a vehicle being run into; or by the horse running away and coming in contact with some obstacle. Any synovial cavity within the body may be penetrated by an unfortunate combination of circumstances; or by the unbridled passion of the groom, who may have a pitch-fork near at hand. So, also, they have been cut into by the arrogance of unskilful operators. However, it matters not how the misfortune may arise, the mode of treatment and the manner of cure is in all such cases exactly the same.

Neither, as regards the primary effect, is it of subsequent importance whether air be admitted into an opened bursa or sac, a synovial sheath, or the interior of a joint. All of these structures are formed into bladders or closed cavities. They all contain a similar secretion, which is a transparent, albuminous fluid, resembling white of egg. They all are of one use, or all serve to facilitate motion. The bursa is the smallest; the synovial sheath is the next in magnitude; and joints may be much the largest. The secondary effects are proportioned to their size; but, in the first instance, much constitutional disturbance will attend the opening of each.

These structures are not formed to endure the presence of atmosphere; air is admitted a short time after each displays inflammation. This creates symptoms of irritability; and air will enter before we see the wound. The secondary effect is, however, most to be dreaded. Bursæ are small bladders, or closed sacs, distributed over the body, and located wherever the natural motions possibly might originate friction. Sheaths always embrace tendons, being essentially closed sacs. The secondary effects of tendonous sheaths are so much more to be dreaded than those attending a punctured bursa, because the last generally lie loose between highly organized parts; whereas, a sheath is partly fixed upon a tendon, and tendon, being lowly organized, is more difficult to cure, when it is diseased. However, joints are much worse than the preceding two; because in these the synovial membrane is partly spread over the cartilage, which lies upon the articular surfaces of bones. Now, cartilage is the most lowly organized substance in the entire body. When disease fixes upon it, the morbid condition is so low, so irritating, and so difficult to eradicate, that science almost despairs of the issue.

The results indicated show that every effort should be made to ward off the secondary effect. Therefore, when an accident of this nature occurs, proceed with the utmost gentleness. Having procured a large sponge and a pail of milk-warm water, saturate the sponge and squeeze it dry, above the injury. Do not touch the sore, but allow the fluid, as it gravitates, to wash off all or any foreign matter. With regard to the wound, dirt seldom enters that. When it does, the suppuration, which must ensue upon the accident, will more effectually remove it than could hogsheads of water, however unfeelingly it might be employed.

The part having been rendered clean, the wound is to be attentively observed. When nothing but blood or serum, or thin discolored fluid can be seen, this argues the more important structures are entire. Should there be among, and yet distinct from those discharges, a transparent glary liquid flowing forth, such is absolute proof some synovial membrane has been severed. The size of the current and the abundance of the secretion are, also, evidences not to be despised. Probabilities may be inferred from these circumstances. If the amount of synovia is small, there is hope that a bursa only has been interfered with; when the amount is large, it demonstrates that either a sheath is punctured, or the joint itself may have been opened. Synovial cavities, between bones, may be larger, and are much more active than the sheaths of tendons; therefore, the magnitude of the current should be observed; although when the integrity of many parts has been destroyed little absolute dependence will be placed upon the comparative quantity of the synovial secretion.

[The conclusion of this article from the *Turf, Field, and Farm*, must be deferred to another issue.]

Ring-Bone.

To the Editor of The Canada Farmer.

Sir,—About two years ago I had a valuable half-blood mare, then nine years old, affected with ring bone on the nigh or left fore foot. I blistered it with the following mixture:—Spanish flies, 1 oz; spirits turpentine, 1 gill; high wines, 1 pint; I applied the same twice a day for ten days, and she was then better until the summer of 1867, when the swelling began and grew very rapidly, and she got very lame. I then applied to a farrier, who cut her in the heel and took out the feeder of the ring-bone, and cut three gashes with an inch chisil and filled the cuts with some white powder; and bound it up for three days, after which I blistered with the following compound for about fifteen days:—Spanish flies, 1 oz.; corrosive-sublimate, ½ oz.; euphorbium, ½ oz.; spirits of turpentine, 1 gill; high wines, 1 pint. The farrier asserted that the ring-bone could not grow again after that treatment. The mare was better from that time until the past month (Sept., 1868), when the affection appeared again, also one on the off or right fore foot. If you know of any means of destroying the ring-bones and saving the mare, let me know, and you will greatly oblige

Ramsay, Oct. 5, 1868. W. W.

Note by Ed. C. F.—We have before had occasion to remark on the uselessness of the practice above referred to as "cutting out the feeder," a practice which is based on entirely erroneous views of the nature of ring-bone, which is altogether a bony deposit, and cannot be affected by the removal of a small portion of cellular tissue. For ring-bone of long standing "firing" is sometimes resorted to with advantage; but in a majority of cases great benefit is derived from the use of an ointment made of biniodide of mercury and lard, in the proportion of one part of the former to six or eight of the latter.

The Dairy.

Philadelphia Butter.

If there is one department of the Dairy in which, more than any other, there is deficiency among Canadian farmers, it is in the process of butter making. So, at least, one must judge from the quality of the article called butter that finds its way into our city markets, and much of which is nothing less than a disgrace to any rural community. It is simply offensive to any but the coarsest taste, and can neither be a wholesome nor palatable article of diet. Since the introduction of the factory system of cheese-making into this country the scarcity of good butter has increased, and the high price which this produce of the dairy now commands, has not in the least degree improved its general quality. We are persuaded that a prime article would bring a very remunerative return to the maker, and that any firm or private individual who could establish a good reputation in this business would realize prices considerably above the ruling market rates. There are places in the States where the quality of butter is especially excellent, and perhaps no part of the country can boast a better name in this respect than the neighborhood of Philadelphia. An interesting account appeared recently in *Colman's Rural World*, of the butter-making process in this beautiful region of Pensylvania. The account is given by a party of farmers who visited the locality to learn by what special means the high character of "Philadelphia Butter" was attained. The cattle on the farm described were of the Jersey breed, and to this circumstance the excellence of the dairy produce was in a measure attributed, but the punctilious cleanliness, the fresh air, the equal and moderate temperature, and the general arrangements of the establishment, no doubt contributed mainly to the successful results. We commend to the attention of Canadians the following description of a Pennsylvania dairy:

"The milking house is a light wooden structure, with so many open doors and windows that it is hardly more than a shed. In winter it is closed up and used as a stable for young stock. In size it is about twenty-two feet by thirty-six, with a row of stanchions on each side, and with mangers in which a little bran is put at each milking time. Each cow has her own place, with her name, age and pedigree over her manger, and she always goes to it as though she could read. Their names have been put up in the order in which they come from the pasture. The 'master' cow entering first, and the less plucky last.

"The milking is done by women, the same one always attending to each cow, and it is done rapidly and quietly, no unnecessary talking and no sky-larking being allowed. We measured 'Niobe's' yield and found it to be eleven quarts (she gave nine the next morning—making twenty for the two milkings), not bad for a butter-making Jersey cow. The others gave less—the smallest not more than eight quarts at two milkings—but the whole herd of eighteen cows could not have given less than two hundred quarts a day, and this of milk that yields over twenty per cent of cream.

"Near by the milking house is the 'spring-house,' the institution of this region, about twenty-four feet long and eighteen feet wide, built of stone set deeply in the hill-side and its floor about four feet below the level of the ground at the down hill-side. The site is that of a plentiful spring, which is allowed to spread over the whole of the enclosed area to a depth of about three inches above the floor of oak laid on sand or gravel. At this height there is an over-flow by which the water passes to a tank in an open shed at the down hill end of the house. On the floor of the spring-house there are platforms or walks to be used in moving about the room, but probably three-quarters of the space is occupied by the slowly-flowing spring water. The walls are about ten feet high, and at the top; on each side, are long, low windows, closed only with wire cloth, which gives a circulation of air at the upper part of the room. The milk is strained into deep pans of small diameter, that are kept well painted on the outside, and are provided with bails by which they are handled. The depth of the milk in the pans is about three inches, and they are set directly upon the oak floor; the water, which maintains a temperature of fifty-eight degrees Fahrenheit, surrounding them to about the height of the milk.

"The cream is taken off after twenty-four hours, and is kept in vessels having a capacity of about twelve gallons. These vessels are not covered, and as the room is scarcely warmer than the water, the cream is kept at about fifty-eight degrees or fifty-nine degrees until it is put in the churn.

CHURNING.

"The next morning we rose at half-past four to see the churning and butter making. The churn is a barrel (bulging only enough to make the hoops drive well) with a journal or bearing in the centre of each head, so that it may be revolved by horse-power. This barrel has stationary short arms attached to the inside of the staves, so arranged as to cause the greatest disturbance of the milk as it passes through them in the churn. At one side is a large opening secured by a cover that is screwed firmly into its place—this is the cover or lid of the churn. Near it is a hole less than an inch in diameter, for testing the state of the churning and for drawing off the buttermilk. This is closed with a wooden plug.

"The churning lasted about an hour, at the end of which time it was necessary to add a little cold milk to cause the milk to gather. This being secured, and the buttermilk drawn off, cold water was twice added, a few turns being given each time to the churn, and when the last water was drawn off it came nearly free of milkiness. A crank was then put on to an arm of the churn, the horse-power thrown out of gear, and a gentle rocking motion caused the butter to be collected at the lower side, directly over the small hole, through which the remaining water escaped. It was left in this condition about two hours. After breakfast we returned to see the working of the butter.

BUTTER-WORKER.

"In one corner of the spring-house stands the butter-worker, a revolving table about three feet in diameter. The centre of this, for a diameter of twelve inches, is an iron wheel with a row of cogs on the upper side of its rim. From its rim to the raised outer edge the table (made of wood) slopes downward, so that as the buttermilk is worked out it passes into a shallow groove and is carried away through a pipe which discharges into a pail standing below. Over the sloping part of the table there works a corrugated wooden roller, revolving on a shaft that is supported over the centre of the table, and has a small cog-wheel that works in the cogged rim of the centre wheel, and causes the table to revolve under the roller, as this is turned by a crank at its outer end. Of course the roller is larger at one end than at the other, so as to conform to the slope of the table, and its corrugations are very deep, not less than two inches at the larger end. Supported at each end of the roller and on both sides are beveled blocks, which, as the table revolves, force the butter from each end toward the centre of the slope. About twenty pounds of butter is now put on the table, and the roller is turned, each corrugation carrying through a long narrow roll, which is immediately followed by another and another, until the whole table is covered. The roller does not quite touch the table, and there is thus no crushing of the particles. The beveled blocks slightly bend these rolls and crowd them toward the centre of the sloping part, so that when they reach the roller again they are broken in fresh places, and by a few revolutions are thoroughly worked in every part.

FINAL PROCESSES.

"Then follows a process that was new to all of us—the 'wiping' of the butter. The dairy maid (in this instance a lusty young man) turning the roller backward, with the left hand, so that the butter comes through all the right hand side, presses upon every part of it a cloth which has been wrung dry in cold spring water, and which he frequently washes and wrings out. This is continued until not a particle of water is to be seen in the butter as it comes from the roller, to which it begins now to adhere. If there is any secret in the making of Philadelphia butter, this is it; and it has much to do with its uniform waxiness of texture, whether hard or soft.

"After this, the butter is salted (an ounce of salt to three pounds of butter)—still by this machine, and any lurking atom of moisture is in this way prevented from becoming a cause of rancidity.

"When the salt is thoroughly worked through the whole mass, the butter is removed to a large table, where it is weighed out and put up into pound prints.

"The working, wiping and salting of over one hundred pounds of butter occupied about an hour, and before ten a.m., the entire churning, beautifully printed, as fragrant as the newest hay, and as yellow as pure gold, such butter as only Jersey cream will make, was deposited in large tin trays and set in the water to harden. The next morning it was wrapped in damp cloths, each pound by itself, put in a tin case, each layer having its own shelf, with two compartments of pounded ice to keep it cool, and surrounded by a well-coopered and securely-locked cedar tub, was sent to the Continental Hotel, where we found it on our return as delicious as when it left the farm."

Soiling Milch Cows.

A correspondent of the *Farmer* (Scottish), in an article on several subjects, thus incidentally alludes to his experience in soiling milch cows:—

"For thirteen or fourteen years I have had a dairy of about ten cows. I was confident that they could be kept with more economy, and in a better condition in the house, than by the common way of turning out to grass. I had a capital byre, built seventy years ago, and I think on a better plan than any new ones that I have seen. It could hold nineteen cows, but I only put in ten. It is lofty, though the hay loft is over, but I keep no hay there. The cows are all tied up by the neck; the chains being long enough for them to lick themselves, and there are no divisions, so that they can all lie down at their ease. I use no litter, but a little sawdust, and I find I can keep them far cleaner than with straw.

"I began, according to the custom of the country, to turn them out for an hour to get a drink and lick themselves. I found that they knew, as well as the byremen, the hour they were to get out, so they were fidgety and restless for half an hour before the time. They had not been out a quarter of an hour when they stood at the gate wanting to get in again, so I said, as they did not know their own minds, they should not get out again, and they never have since.

"I have four cows that I reared as calves that have never had their foot in a grass park—indeed, have never been out of the byre except to go about a mile to the bull. I have fed a great many rat—and the best beef I ever tasted—some *entirely* on grass *cut from a water meadow*, and some got cake; but I have not made up my mind which is cheapest; those that got cake *may be* somewhat fatter, but as to quality there is no difference."

Poultry Yard.

Standard of Excellence in Exhibition Poultry.

TURKEYS.

Head and Face—Very bright and rich in colour.
Eyes—Bright and clear.
Body—Long and deep.
Wings—Powerful and well carried.
Breast—Broad, very long, and perfectly straight.
Thighs—Muscular, straight and strong.
Legs—Very strong, and perfectly straight.
Plumage—Sound, hard, and glossy.
Colour—Rich, the birds matching in the pen.

POINTS.

Size	6
Symmetry	4
Richness of colour, and matching in the pen	3
Condition	2
	15

DISQUALIFICATIONS.

Crooked breasts, backs, or legs, or deformity in any part.

DUCKS.

AYLESBURY.

GENERAL SHAPE AND COLOUR.

Bill—Long and broad; when viewed sideways, nearly straight from the top of the head to the tip of the bill; of a delicate pale flesh colour, perfectly free from black or dark marks.
Head—Long and fine.
Neck—Long, slender, and gracefully carved.
Body—Long and deep.
Back—Long and broad.
Wings—Strong, carried well up and not drooping.
Tail—Feathers stiff and hard, with hard curled feathers in the drake.
Thighs—Short.
Legs—Short and strong; bright light orange colour.
Plumage—Pure white throughout.

POINTS IN AYLESBURY DUCKS.

Purity of colour and shape of bill	3
Size	4
Symmetry	3
Purity of colour in plumage	3
Condition	2
	15

DISQUALIFICATIONS.

Birds so fat as to be down behind, bills deep yellow, or marked with black, plumage of any colour except white.

ROUEN DUCKS.

GENERAL SHAPE AND COLOUR—THE DRAKE.

Bill—Long, broad, and rather wider at the tip than at the base; when viewed sideways, nearly straight from the crown of the head to the tip of the bill; the longer the better. Colour, greenish yellow, without any other colour except the black bean at the tip.
Head—Long and fine; rich lustrous green.
Eye—Dark hazel.
Neck—Long, slender, and neatly curved; colour, the same lustrous green as the head, with a distinct white ring on the lower part not quite meeting at the back.
Breast—Broad and deep; the front part very rich purplish brown, or claret colour; free from grey feathers, the claret colour extending as far as possible towards the legs.
Back—Long; higher part ashy grey mixed with green, becoming a rich lustrous green on the lower part and rump.
Shoulder Coverts—Grey, finely streaked with waving brown lines.
Wings—Greyish brown, mixed with green, with a broad ribbon mark of rich purple, with metallic reflections of blue and green, and edged with white; the two colours quite distinct.
" *Flight Feathers*—Dark, dusky brown, quite free from white.
Under part of Body and Sides—Beautiful grey, becoming lighter grey near the vent, and ending in solid black under the tail.
Tail—Feathers hard and stiff; dark ashy brown, the outer web in old birds edged with white.
Tail Coverts—Curled feathers hard and well curled; black, with very rich purple reflections.
Legs and Feet—Orange with a tinge of brown.

THE DUCK.

Bill—Broad, long and somewhat flat; brownish orange, with a dark blotch on the upper part.
Head—Long and fine; deep brown, with two light pale brown stripes on each side from the bill past the eye.
Neck—Long, slender, and neatly curved; light brown, pencilled with darker brown, and quite free from the least appearance of a white ring.
Breast, under part of Body and Sides—Greyish brown, each feather marked distinctly with a rich dark brown pencilling.
Back—Long; light brown, richly marked with green.
Wings—Greyish brown, mixed with green, with a broad riband mark of rich purple, edged with white, the two colours distinct.
" *Flight Feathers*—Brown, perfectly free from white.
Tail Coverts—Brown, beautifully pencilled with broad distinct pencilling of dark greenish brown.
Tail—Light brown, with distinct broad wavy pencilling of dark greenish brown.
Legs—Orange; or brown and orange.

POINTS IN ROUEN DUCKS.

Shape and colour of bill	3
Size	4
Colour of plumage	3
Symmetry	3
Condition	2
	15

DISQUALIFICATIONS.

Bills clear yellow, dark green, blue or lead colour; any white in the flight feathers of either sex; birds so fat as to be down behind.

GEESE.

TOULOUSE.

Carriage—Tall and erect; bodies nearly touching the ground.
Colour—Breast and body, light grey; back, dark grey; neck darker grey than back; wings and belly, shading off to white, though but little white visible.
Bill—Pale flesh coulour.
Legs and Feet—Deep orange, inclined to red.

EMBDEN.

Plumage—Uniformly pure white.
Bill—Flesh color.
Legs and Feet—Orange.

POINTS IN GEESE.

Size and weight	6
Symmetry	4
Colour	3
Condition	2
	15

WILD TURKEY—CANADA WEST. *

Head and Face—Clean and game-like, with less excrescence than in the tame bird,—Neck, where bare of feathers, of a darker blue.
Eyes—Dark, very bright, full of intelligence.
Body—Broad shouldered and deep-chested.
Breast—Deep; hair tuft long.
Wings—Bow of same colour as body, with broad bar of bronze feathers across. Secondaries, light brown grey, pencilled with white—the upper four or five feathers that meet over the back being darker, less pencilled, and shot with emerald green. Primaries black, pencilled with white.
Thighs—Dark greyish brown.
Legs—Long—bright red.
Tail—Long, rich deep brown pencilled with black; carried rather horizontally; no tendency to white or whity-brown admissible; bar at end black.
Plumage—Hard and close.
Carriage—Very elegant, majestic, and game-like.

* The Points of the Wild Turkey given above have been furnished by Col. Hassard.

Colour—General hints purple and rich deep brown, and shot with various shades of gold, violet, vermilion and green, very lustrous in sunshine. White in any part of body except pencilling of wings inadmissible.

POINTS.

Colour of Legs	4
Plumage	5
Size	4
Condition	2
	15

DISQUALIFICATIONS.

Deformity in any part. Legs any colour but red. White at end of tail feathers, or anywhere except in wings. A very light whity-brown at end of tail must be regarded with great suspicion.

HEN.

Similar in plumage to Gobblers; less brilliant, and smaller in size.

The Wild Turkey.

To the Editor of The Canada Farmer:

Sir,—Presuming that you would shortly conclude your extracts from the "Standard of Excellence," and that among the few remaining varieties of poultry the Turkey would shortly be noticed, I have endeavoured, in imitation of that valuable publication, to give the description and points of the wild bird, and send them to you, that you might append them to the corresponding account of the domesticated breed. I am afraid I have but imperfectly described the bird, but I may say that, having submitted the description to several parties who are perfectly acquainted with the bird, they all agree in its general correctness. I may further state, that I took the description from a splendid living specimen, now in my possession, which is exactly similar to those sent by me to Mr. Fowler, of Aylesbury, last December, and from which I am glad to hear he has most successfully raised a large brood. This specimen has been inspected by sportsmen and others, all of whom pronounce the bird to be the correct thing. I have also compared the points set down by me with dead specimens, seen plentifully in our markets in the winter, and also with stuffed and live specimens from the States. I therefore think that, until some abler pen portrays the bird, the description may be accepted as correct.

I have been thus particular in giving my authority, as I have reason to suppose that at the last Provincial Exhibition, at which I had the honour of being one of the judges in the Poultry Department, some dissatisfaction was manifested at the awards in this class (Wild Turkey). Some of the exhibitors assured me that their birds had to be trapped to enable them to show them. I do not donbt this for one moment, but it does not prove that these were not a cross between the domesticated and wild species, as their plumage evidently pointed them out to be. A considerable number of the Turkeys in Canada have a cross of the wild bird, and it is perfectly possible to shoot, in the localities where the wild birds are found, birds with the "bar sinister"—white, or whity-brown, at the end of the tail. The farmers allow their birds to roam in the woods, and crosses thus occur. Indeed, no later than yesterday, a distinguished fancier and exhibitor informed me that two splendid wild hen Turkeys had come into his yard a short time since, and joined their domesticated congeners, but on his trying to catch them they had immediately taken wing. Under these circumstances, I think it more essentially necessary that the true birds should be properly described, so that no mistake can occur in the award of premiums for the different classes.

I may perhaps add further, that I have seen practical proof in two instances of the cross of the so-called wild birds, bred from birds trapped, and bought from Indians, and about which I was assured there could be no possible mistake, and that they were the genuine wild Turkey. In both cases alluded to, white birds were hatched among others from the eggs of these birds—pretty conclusive evidence that mistakes do occur. There were no white birds near these birds in the breeding season; they have the white-ended tail and other feathers, but were splendid in plumage; and from the respectability of the parties no deception could have been intended; they firmly believed they had the correct thing. I have seen, continually, similar birds exhibited in the Wild Turkey classes at every exhibition which I have attended in Canada. It does not therefore follow, that because your pigs take a six months' roam in the woods they become wild boars—nor your tame turkeys wild, although in one sense wild enough, and difficult to catch.

F. C. HASSARD.

Toronto, Oct. 1, 1868.

The Apiary.

Will Bees Build Straight Combs in a Frame Hive?

This question is often asked by bee-keepers who have never used a frame hive. We would answer, they will build both straight and crooked combs; but as it is very desirable that they should always build straight, it is well to understand how we may secure such. First, it is absolutely necessary that we use a properly constructed hive—a hive in which especially the frames are properly adjusted. If the lower edges of the top-pieces of the frames upon which the bees are to build their combs are not at proper distances from each other, it will be almost impossible to get them to build straight. But when the frames are properly adjusted there is not much difficulty. A little attention will secure combs straight enough for all practical purposes. If a hive be examined four or five days after a swarm is put into it, any inclination to build crooked may then be remedied by simply pushing them back to their places with the hand. The combs are soft, and will not easily break. If very much inclined to be crooked, they may require another examination. Or if bee-keepers would take the trouble to rub a piece of bees-wax over the edges of the comb frames before the bees are put in, they would have but little trouble with crooked combs.

Securing Combs in Movable Frames.

It has long been a fixed rule with us that the less bees are meddled with the better. Hence whatever we do to them we would wish to do quickly, and in no case is this more urgent than in the transferring of comb and bees from the old-fashioned hive to the Langstroth hive. One of the operations that has always taken us some time is the securing of the comb in the frames until the bees have had time to fasten them. At first we used twine. Then it occured to us that annealed wire, which required no tying of knots with gloved hands, would be better, and we, in common with others, have used it freely. Having occasion the other day to transfer a stock from the old box hive to one with movable frames, we prepared a few little articles which we found to be of great convenience.

Out of well annealed iron wire (No. 12) we made a dozen oblong loops or links, 1½ inches wide, and long enough to go over the outside of the frames and leave half an inch to spare. As soon as a sheet of comb had been cut to fit a frame, it was slipped into its place, and then the loop was slipped on and made tight, by giving it a slightly diagonal direction across the frame. In one or two cases we fixed it more securely by means of a small wedge. The construction and operation of these loops are so simple that no further explanation can be necessary. With one on each frame we found that the comb was secured from all danger of falling out. Two or more might be used, however, in special cases. We applied ours horizontally—that is, *lengthwise* of the frame—but we have since made some of such a length that they fit over the frame *vertically*, and are secured at the bottom by means of a small wedge. On trying these with some loose comb and frames that we happened to have by us, we think that in some cases—especially where the comb is thick and irregular—the vertical loops fastened with a wedge are the best. Both forms can easily be removed, as the sides can be readily sprung apart so as to clear the comb, and even with gloves on it is but the work of a moment to apply or to remove them.—*Cor. Co. Gent.*

Correspondence.

Social Disadvantages of Farm Life.

To the Editor of The Canada Farmer:

Sir,—So much has been written and said about the beauties and pleasures of rural life, that some people hardly believe that it has any disadvantages: but like everything else, agriculture has two sides, a dark and a bright one; and although the advantages preponderate, still there are disadvantages which should not be overlooked. Farmers often reside a considerable distance from the school-house, and the children are frequently kept at home by distance, muddy roads or snow-drifts; thus in their early years losing the time when their parents can the better spare them from the farm-work. If a farmer wishes to give his children a liberal education he has to send them away from home—where they will be beyond the reach of home influences—to the village grammar school, or town academy. But the obstacles in the way of an early education might be overcome to some extent by the parents or older brothers and sisters taking an interest in teaching the children, when prevented from attending school. And although farmers' children may be older than those of mechanics and dwellers in cities before they get their education, yet when sent to higher schools, they generally make better proficiency during their attendance. Much also may be done in after life by self-education during the long winter evenings. But after all that can be said, the education, or rather want of education of farmers' children is to be lamented, and is one of the disadvantages attending their calling.

Farmers are also often distant from the church and sabbath school. For although people in the country may not have those peculiar temptations to vice and wickedness incident to towns and cities, yet they cannot live as they ought without worshipping the Almighty in His sanctuary, or having the sabbath school as a nursery for the church. But if farmers during inclement weather are deprived of these means they are not deprived of the sabbath, and should have proper books and papers for reading for themselves and household.

The distance which most farmers necessarily live apart gives each family a degree of seclusion, not only from each other, but from mankind generally. This often gives rise to a dread of going into society. The young folks feel very awkward and bashful when they appear before "company," and indeed often are awkward; they cannot carry on an intelligent conversation for any length of time with any degree of ease, even supposing they have a tolerable English education; their manners are neither polished nor easy; they may be guileless and affectionate, but from want of politeness they may appear very rude to the more polished part of society. If a person has ever been at an evening party in the country he will see that the time is occupied in frivolous plays, while no time is allowed for profitable conversation. Suppose some "city" cousins drive out with a few friends to visit some of their friends or relations, whenever they get in sight of the farmer's residence there is a general scamper among the children, the elder ones trying to get good places for viewing the visitors without any danger of being seen; the garret and dog-kennel have to be general hiding places for the time being; there is confusion in the house, the mother looks at her dress, then in the glass, then at the parlour, to see if everything is in order; the father looks up at the sky so as to have a few words ready about the weather. The visitors arrive, are received rather nervously by the mother, and are hurried off to the cold "north room" without much ceremony; the children come back one by one, when there is a general "cleaning up" from head to foot so as to be ready when the meal time comes; the mother buries herself cooking and baking for tea, leaving the company to entertain themselves as best they can; and it is not until after tea that there is a feeling of sociability, when it will be soon time for the company to return home. The above picture has many a counterpart in the families of the farmers through the country, and is often repeated. The children have to be well into their *teens* before they are able to keep their ground when their "city cousins" come. But there are families where the reverse is the case; the mother can receive company with ease and grace; the father can talk fluently on religion, politics, the topics more immediately and directly relating to our country, and probably also on different scientific subjects, evincing altogether no mean acquaintance with the literature of the day; and the children are intelligent and refined. Ignorance and boorishness are no necessary concomitants of farm life.

Again, there is often not that air of neatness about the dress of the farmer's family, or the furniture of the house, or the plan of their flower gardens that we find in or near cities. Farmers and their families have to work very hard, although not so hard as their forefathers have done. They are also said to be given to grumbling,—are never satisfied—the crops are either too light or too heavy—the weather too hot or too cold—the land too wet or too dry—the prices too low—he has bad fortune with his stock—or indeed anything is a fit subject for grumbling. Now there may be some truth in this accusation, and this discontented spirit should be avoided by the farmer. The foregoing are some of the disadvantages of the farmer's lot, and others might be mentioned—enough to convince those people of their error who believe there are no toils, nor hardships, nor inconveniences attending rural life.

All that has been said of the pleasures of farm life is true; and how inconsistent is the empty praise of those poets and sentimentalists who write so much about the beauties of farm life, and yet do not engage in it themselves, nor educate their children for agriculturists. What can we get in this world, or what pursuit can we follow that has no disadvantages? There are few callings, on the whole, more healthful, pleasant and noble than that of the farmer. As for the writer—

> "A farmer's life is the life for me,
> I own I love it dearly."

CULTIVATEUR.

York, Sept. 1st, 1868.

The Canada Farmer.

TORONTO, CANADA, OCTOBER 15, 1868.

The Western Fair.

The above fair, held under the auspices of the East Middlesex and City of London Associations, came off on the 29th and 30th ult., at London, and must be pronounced a decided success, although the weather, especially on the second day, was far from favourable. Owing to the Crystal Palace being occupied by the military, the Drill Shed was used for such articles as required to be placed inside a building, while the live stock was shown on the ground adjacent to the Palace. Of course a local fair must not be judged by the standard of a Provincial exhibition; yet it must be confessed that in some departments the London show was no way inferior to its great predecessor at Hamilton, while as a whole it was every way creditable to its projectors and promoters. In horticultural products, with the single exception of grapes; in ladies' work, in carriages, and in poultry, the display was fully equal to that to which the entire Province contributed. The attendance of visitors was large, and financially, as well as otherwise, the exhibition was a success.

In briefly mentioning the leading features of the show, it may be well to begin with

THE LIVE STOCK.

The horse classes were well filled, especially the heavy draught, general purpose, carriage and blood horses. Two heavy draught stallions are particularly worthy of mention: "Farmer's Glory," owned by A. McTavish, of Lobo, and the imported horse "Phenomenon," owned by A. Laurie, of London. Robt. Murray, of Westminster, Wm. Saddler, of Dorchester, J. W. Lurg, and T. McLean, of Lobo, showed some fine-looking horses and mares for general purposes. In carriage and buggy horses the competition was keen, there being over sixty entries. Beautiful blood horses were shown by Messrs. Monger, of Lobo, and McArthur, of Westminster. Some very nice farm teams were on the ground. Of cattle there were fine specimens in the Durham, Devon, and Galloway classes. Messrs. Peters and Pincombe were the chief exhibitors of Devons, but it would require a much longer list to enumerate the Durham exhibitors. At all our fairs, whether provincial or local, this choice breed of cattle takes the lead. Mr. George Robson got the largest share of the honours in this department. Some fine Durham and Devon Grades were shown, and gave proof of the improvement that may be effected in our native cattle by the infusion of a little better blood into them. A few yokes of working oxen were shown, Mr. Geo. Robson having the best pair. Some good specimens of fat cattle were also exhibited by Messrs. Simmons, Pincombe, and Walker. A large number of sheep were on the ground, the Leicesters greatly predominating, and comprising some as fine samples of the breed as can be found anywhere in Canada. We cannot say as much for the Cotswolds, though some fair animals were exhibited. The Southdowns were rather inferior in quality and limited in quantity. The porcine tribe was not largely represented, and consisted almost wholly of large and small Berkshires and Suffolks. Some of them were extremely well-bred, and showed that the farmers of the West understand the difference between land-pikes and hogs properly so called. London is noted for its first-class poultry, and in this department there was a truly magnificent display. Messrs. Peters, Boyne, and Routledge, were the chief exhibitors. For some reason or other, Mr. Lamb did not show any of his choice collection of fowls. A few pairs of pigeons were on the ground.

IMPLEMENTS.

The show of these was hardly so extensive as we expected to see, though it was considerably larger than any other local fair we have attended. Specimens of Ball's Ohio Combined Reaper and Mower, were shown by J. Elliott, of the Phœnix Foundry, London, and F. W. Glen, of the "Joseph Hall Works," Oshawa, those from the latter establishment having a raking attachment. The "Ayr Combined" was shown by Mr. J. Watson. Grain drills and cultivators of superior workmanship were shown by various parties. Among the cultivators was "Anderson's Patent Vibrating Cultivator," exhibited by Stewart, Bruce & Co. "Anderson's Combined Pea Harvester and Hay Rake" attracted much attention. This implement was not long since subjected to thorough trial on a farm in London Township. It will pull from eight to ten acres of peas per day, and is also a most effective hay rake. Its cheapness is no small recommendation to it. The price is only $20. Seed drills of different sizes were exhibited by Messrs. Wm. and Jas. Walker, of Westminster. Mr. George Murray, of Westminster, had a hand grass sower, and a one-horse combined grain and grass seed sower, which, though not highly finished, seems to do its work well. Messrs. Maxwell & Whitelaw, of Paris, exhibited a seed drill for sowing all kinds of seed; also, a powerful cider mill. Hon. E. Leonard had one of his noted wood-sawing machines, which is, we believe, second to none for efficiency and economy of power. Some beautifully made ploughs were on the ground, the chief competitors being Geo. Grey, of London, and J. McSherry, of Iona. Two ploughs, one wooden and the other of iron, made by R. Hornsley & Sons, of England, were exhibited. A ditching machine was shown by Robt. Robson, a horse hay fork by Eliot Grievo, harrows by Jacob Metzer, pumps by Nelson Reynolds and J. M. Cousins, lumber waggons by Plummer & Pacey, and Hull and Kennedy, a farm cart by

Robt. Murray, and straw cutters by J. M. Cousins. Cradles, rakes, scythe snaiths and tool handles, were shown by T. Bryan, an exhibitor who got no less than seven premiums at the Provincial Fair for these articles.

FIELD AND GARDEN PRODUCTS.

The show of grain was exceedingly good, including fine samples of wheat—fall, spring, and midge-proof; together with barley, peas, oats, and Indian corn, that looked as if the season had been anything but the unfavourable one it has. Good samples of clover, timothy, and flax seed were shown. A splendid display of turnips, carrots, mangolds and potatoes, was on the ground. The vegetables were much better than could have been expected after such a dry, hot summer as we have had. Two fine sheaves of flax were shown with the seed on. Several bales of hops, of excellent colour, were exhibited. Very fine cabbages were shown by several parties; tomatoes, of all sorts and sizes, were conspicuous among the garden products; particularly good cauliflowers made the mouth water; and specimens of the egg plant, looked like shiny bladders of purple snuff. A superior collection of fruit was exhibited, consisting mainly of apples, pears, peaches, plums and grapes. The array of flowers was varied and attractive, and a very fine collection of green-house plants attracted much attention. Foliage plants of rare beauty were especially conspicuous in this department. Some very tasteful floral designs were to be seen, one of which, representing a huge cornucopia, was particularly pretty. It is pleasing to see evidences of a love of the beautiful in nature, going hand in hand with regard to the necessary and useful.

MISCELLANEOUS.

Under this head we must dispose very summarily of a great variety of things on which it would be easy to dilate, and that are well worthy of especial mention. As already intimated, there was a fine show of carriages, among them a splendid cab, made by Mr. J. Campbell of London. Beside him, Abbot Brothers, Thompson & Moran, Smith & Gordon, McKeller & Stewart, Pavey & Sons, Messrs. Shetwell, & Hodgins, showed vehicles of various kinds and of superior workmanship. The fine arts, fancy work, and home manufactures, were well-filled departments, but we cannot attempt details respecting them. Beautiful specimens of hand, weaving in carpets, coverlets and shawls, were shown by Mr. Wm. Patrick, of London Township, and attracted much notice. A very fine collection of marble work was exhibited by Messrs. Teale & Wilkins; also, some very nice modellings, and a piece of sculpture representing a figure of "Grief," which was much admired. A beautiful assortment of furniture was shown by Mr. Moorhead, and a large assortment of stoves by the Messrs. McClary and M. Anderson. Washing machines and wringers, hubs, spokes, and bent stuff for carriages, were quite conspicuous articles. A patent horse-shoe, contrived to prevent balling with snow in the winter time, was shown by Mr. Cooper, of Strathroy, and a lever spring wheel by Mr. McLaren, of the same place. A superb collection of furs drew many observing and admiring eyes. Musical instruments; sewing machines; silver ware; crockery; fire-arms; plain and fancy bread and biscuit; cheese, both dairy and factory; leather goods; specimens of book-binding; samples of vinegar, currant wine, and perfumery; articles of brass foundry; collections of brushes; dressed skins; gloves and mitts; sugar-cured hams and bacon; starch from the Ontario starch works; selected grocery goods; live bees, hives, and honey, made up a miscellany deserving of close attention, and presenting many features of special interest.

The London people deserve much praise for the spirited manner in which they have sustained this fair, as do the farmers of the surrounding country for the efforts they have made to present a display of stock and farm products worthy the great fame of the Western peninsula. Though we have no idea that this Exhibition was got up in any improper spirit of rivalry, yet there seems to be an idea entertained by the people of London and the surrounding country, that they are not appreciated by the rest of the Dominion as they deserve to be, and certainly such demonstrations as the one we have been chronicling will do much to impress outsiders with the great resources and high pitch of agricultural improvement characteristic of this part of the province. We regretted to find a notion prevalent in some minds that the Canada Farmer is unduly jealous of the reputation of Toronto and the adjacent region, and disposed to slight the claims of the young sister city at the west, and its neighbourhood. We can most honestly declare that there is no such feeling entertained by us, but that, on the contrary, we are always glad to record whatever is of interest to the farming community, wherever it may transpire, so far as we have information and can spare space. As one evidence of this, we attended, at considerable inconvenience, the recent Western Fair, and have with great cheerfulness bestowed the meed of commendation on those concerned in its origination and management. We beg our London friends to drop all suspicion of local jealousy, and to believe that we are always ready to co-operate with them for the good of our whole country, and any part thereof.

New York State Fair.

The twenty-eighth annual fair of the New York State Agricultural Society, was held this year at Rochester, from Sept. 29th to Oct. 2nd. In no other city of the State are these exhibitions so successful as at Rochester. It is central, has convenient, spacious, pleasant grounds, and is, withal, easy of access. We journeyed to this favourite point with "great expectations," and they were not disappointed, for the show was all that could be desired. When the New-Yorkers get up a State exhibition, they mean business, and lay aside all thought of horse-racing, side shows and pleasure-taking. Their energies are honestly bent to the work in hand; hence it is not surprising that from year to year there is visible progress, while they far outshine their sister States, who have no faith in agricultural shows for agriculture's sake, but must bait their traps with tit-bits of jockeyism and gambling. Judging by the crowds who attend on these occasions, the people of New York State appreciate an agricultural exhibition, and do not require extra excitements of a foreign nature to allure their presence and patronage. Even the horses do not seem to require the impetus of a race to urge their attendance. The equine display at Rochester was quite as varied and meritorious as that brought together at New Haven a short time previously, where the race-course vied with the showring. Indeed at any American fair, whether State or County, you may count on a fine array of horses. The American citizen who is not fond of a fine horse may be set down as a *rara avis*. One of the earliest and strongest aspirations of boyhood, in the United States, is to be able to handle the ribbons; and "Young America" is in his glory with a fast horse in the thills, a cigar in his mouth, and beauty beside him on the other half of the buggy cushion.

The heavy draught and general-purpose classes were better filled on this occasion than we ever remember to have seen them at an American fair. In our view, it is one fault of the agriculture of the United States that the plough teams are too light. It is difficult to breed horses that are adapted both to the furrow and the road, because a dead pull is wanted in the one place, and at least a fair degree of speed in the other. In carriage horses the turn-out was, as usual on such occasions, very fine, and if the judges were not puzzled where to award the honours, the spectators were embarrassed where to bestow their highest commendation and preference. The entire "get up" of the "rigs," as Americans call horses, harness and vehicles, is such as to impress a stranger with the great attention bestowed on equipages across the lines. There is a style about these turn-outs which evinces the prevailing taste of the people.

For obvious reasons, the cattle and implement departments attracted our chief attention; we shall therefore devote the greater part of the space we have at command to some notice of them.

The show of cattle of all breeds was in excess of any former exhibition that we have attended in the State of New York. Short Horns as a class were very good indeed. C. K. Ward, of Leroy, N. Y., had on exhibition a lot mainly of his "Hopes," coming from "Hopeless," by "Horatio,"—imported by the Livingstone County Company, which in Mr. Ward's hands fully sustain their high reputation. Wm. W. showed the bull "Monarch," by "Oxford Lad," an animal much like his sire in color and points—also, a young bull by "2nd Duke of Geneva," out of the fine cow "Constance 2nd," and as might be expected from the union of such parents, the calf is a choice one.

Hon. A. B. Conger showed a herd of cows and heifers of rich breeding, but too low in condition to do justice to their blood or breeder; also, a large, grand aged bull, bred by Mr. Thorne. Craig Wadsworth had a lot of good, useful-looking animals, evidently direct from their pastures without special preparation for a show. Messrs. Wolcott & Campbell showed some good young things, and a fine cow, "Grace Darling," much resembling the well-known show cow "Miss Belleville," from which cow "Grace Darling" remotely descends.

Hon. Ezra Cornell came out this year in great force, but for lack of a show bull did not enter for the herd prize. A light roan, "Princess," is the best of her family we have seen, an even, level beast. A red yearling of the "Lucy Ann's," a strain, Mr. C. is very partial to, descending from the cow "Caroline," by "Dashwood," imported by Walter Dun, of Kentucky, in 1836, shows the capacity of Short Horns for early maturity. She is full in all her points, and particularly good in her crops and heart. A roan "Lucy Ann," two years old, is much like the above in her general characteristics. "Kirkleavington," a rich roan, three year old heifer, by "3rd Lord of Oxford" (exported to England), is a capital specimen of the Bates' blood, with a strongly marked head, rough, but waxy horn, short fine neck, brisket wide, deep and projecting, well filled crops, with extraordinary wide loin, hips and rump, filled with flesh of first quality—as a whole one of the very best tops we recollect on a young cow. Her defects are those of her blood; she is too thick and heavy in her shoulders, and this makes a slight flatness in the fore ribs look worse than it is. All Mr. C.'s stock show evidence of careful training.

Mr. M. A. Cochrane, of Montreal, added largely to the attraction of the Short Horn show, taking, as he did, the gold medal for the best herd, with the young bull "Baron Booth," a very evenly good, red eighteen months' beast, strongly dashed, as his name indicates, with Booth blood. The cows were, "Sanspareil," a great, strong beast, bred by Mr. F. W. Stone, of Guelph, with grand hind quarters; the beautiful, white three-year old heifer "Snowdrop;" "Maid of Athol," a red and white three-year old, very even, stylish and attractive, with promise of a distinguished career in the show-yard, if she is gone on with; "Maggie," a red two-year old, very neat and stylish, but stripped of some of her points by her calf;—but all the cows and heifers just named pale before the world-renowned cow "Rosedale," so well known on two continents as to need no description. We were glad to see that "Rosedale" gives promise of adding a calf to the Compton herd within a few weeks, by the "11th Duke of Thorndale." Mr. Cochrane also showed a yearling heifer, a good specimen of Major Duncan's breeding, and the heifer calf "Wharfdale Rose," recently imported from England.

In Ayrshires, Messrs. Wolcott & Campbell showed a herd all descending from a beautiful little short-

legged cow, "Handsome Nell;" only one, beside the old cow—"Nannie"—is in milk, and these two show the milk-veins and udders for which the breed is celebrated; altogether a neat lot of cattle. Messrs. W. & C. also showed several good Jersey cows, as did Messrs. Dinsmore & King. Each of these breeders showed very fine aged bulls of the Jersey breed.

In Devons, Joseph Hilton exhibited a lot of ten, and Walter Cole, of Batavia, twenty cows, all good, and some extra. Among the latter sort we place ten "Helenas," descending from the "Helena" importation by Gen. Wainwright. This sort of Devons are usually quite light-coloured, but are quick feeders and often good milkers.

The only Herefords were those forming the herd from Compton, and these were so good that the gold medal was awarded to Mr. Cochrane, although they had no competitors.

In Grades we saw nothing of note. A few Galloways were exhibited—our notes do not give the names of owners. In fat cattle there were no monsters, so attractive to the crowd, and we noticed but some half a dozen good, fairly fed oxen.

As a whole, the cattle show was a good one, and many useful lessons could have been learned from it. Many breeders of Short Horns, for the first time, saw in "Rosedale" a grand specimen of the Booth cow, with her immense carcase and remarkably fine bones. The Short Horns, for the first time in some years, were judged by the scale of points, which in some instances gave decisions at variance with the popular voice. We fancy the show cow that can fill the 100 points of the scale has yet to be bred. Perhaps this pitch will be reached when breeders can unite the excellencies of the two representative cows in the Rochester show ring; the grand, fine ribs, fore flank, heart and shoulders of "Rosedale," with the long, level, wide hind-quarters and flank of "Kirkleavington."

We must not omit mention of the sheep. In this department the Merino usurpation is fast coming to an end on the other side, and the long-wooled classes are asserting their just claims to a division of honour and attention. While the Merinos were present in considerable force, there were also numerous and fine specimens of Leicesters, Lincolns, Cotswolds, and Southdowns. Mr. Cochrane, of Montreal, took first and second prizes for Leicesters and Lincolns, and made a clean sweep of the Cotswold premiums. Some very decent grade sheep were shown. The pig department was well filled, chiefly, however, by the larger breeds, Chester Whites predominating. A really good display of poultry was on the ground, Brahmas, Black Spanish, and Leghorns being especially prominent.

In the Implement Department there was of course considerable similarity between the New York and New England fairs, inventors and manufacturers very naturally making the tour of the fall exhibitions to bring their wares into public notice. We must refer our readers to the very full report of the New England fair which appeared in our issue of Sept. 16th, for an account of such implements as were exhibited on both occasions. At present we shall briefly advert to those which came under our eye at Rochester only. A number of machines were exhibited from the Rochester Agricultural Works, among which were Hubbard's double-speed mowers and self-raking reapers. The advantages claimed by the exhibitors of these machines over others of the same class on the grounds are important. For instance, both driving wheels are going continuously. Furthermore, by changing the gear shifter you increase or lessen the speed or motion of the cutter, so that in a field where the grass is thin there is no necessity for running the cutter so rapidly as to shake the machine almost to pieces. Again, it has no ratchet wheels nor extra gearing to accumulate earth and clog the working of the machinery. "Farmers' Favourite," a continuous feed, double distributor grain drill, from Bickford & Huffman's Agricultural Works, Macedon, N. Y., attracted a good deal of notice, and we will briefly state its merits. It embraces a simple arrangement for putting the drill in gear with the tubes down for work; a double distributor; sowing coarse and fine grain alike, with accurately double and reversible points or tubes, in single row or zig zag as desired. The exhibition given of the distribution of grains by Mr. S. W. Gallup, their general agent, satisfied us that it will distribute all grains with certainty and continuously. The tube lifter accomplishes its work with ease and very little labor. The grass seed and fertilizing attachments are very simple and practical. In this department may also be mentioned McConnel & Jones' street sweeping machine. A. H. Wood had on exhibition a portable engine, which can be employed in threshing, sawing wood, cider making, &c. This engine is mounted on cast iron wheels, hubs and rims four inches wide, with a double set of wrought iron spokes. The wheels raise the boiler high enough to clear any part of the road, so that it can be moved from place to place without detaching any part of the engine. The Pioneer Stump-puller, entered by O. A. Church, of New Berlin, Chenango County, N.Y., is one of the simplest and yet the most powerful machines of the kind. Two men can raise a weight of 25,000 pounds and pull 100 stumps a day with it. The action is quick, it is portable and durable, and the price, sixty dollars, is small to any farmer who has stumps to pull or rocks to dig. Patrick's Improved pump, for watering stock, attracts a good deal of attention. Silas R. Kenyon had a patent Corn Husker, and E. B. Roberts a neat machine for cutting weeds, cultivating and hoeing. There was a good display of the Gordon Empire Feed Cutters, Grain Separators, and Smut Machines of all sizes. The hardware firm of Pollock & Weaver, had on exhibition a large number of Agricultural Implements, comprising Feed Cutters, Shovels, Rakes, Forks, &c., from their establishment in Rochester. There was a great number of Potato Diggers with their various improvements.

"The Iron Clad" is the name of a brick machine in operation on the Fair Grounds. It was exhibited by the inventor, Mr. J. A. Lafler, of Albion, and has several points of excellence. It makes three different kinds of brick; common, pressed and stock brick. Pressed brick can be made with it in rainy weather as well as in fair, and the inventor claims that the work of brickmaking can be commenced three weeks earlier with this than with any other machine. Daniels' Patent Adjustable Wheel Tire Tightener is a very simple and convenient attachment to a wheel, so concealed as never to be noticed, by which the tire can at any time be made perfectly tight by turning a nut. The tire of any waggon on which this tightener is used can be *set* in two or three minutes better than any blacksmith can do it in the usual way, thus saving much time and money. It can be secured by addressing—James Ort, Mechanicsville, Pa.

One of the most useful and durable things to any farmer who works or ever expects to work a mower or reaper, is the Emery Knife Grinder, manufactured by the Emery Grinder Company, Auburn, N. Y. It will grind four times as fast, and last ten times as long as a grindstone—is not affected by sun or rain; grinds out all the nicks and never draws the temper of the steel. For circulars giving full description, address E. G. Starke, Secretary of the Company, Auburn, N. Y.

Two very efficient Ditching Machines were shown, and put to actual trial. The Heth Ditching Machine is strongly-made, simple, and does good work, making a complete ditch by once going over the ground, and leaves it ready for the tiles. It dug a ditch, thirty-five feet in length, in nine minutes. The Chicago Ditching Machine is a still more efficient one. It dug a ditch, forty rods in length, in fifty-two minutes. This machine is considered the best yet known in the United States. It was exhibited by C. H. Beardsley, Secretary of the Chicago Ditching and Spading Company. "Buell's Improved Seed Washer," for washing out apple and other seeds, is worthy the attention of nurserymen and others. It is made by Messrs. Buell, Maulins, N. Y. The "Farmer's Boiler," on a new plan, cooks, heats and steams food for stock at a wholesale rate, and is especially convenient for those who keep a large number of animals. E. E. Sill, Rochester, N. Y., is the agent and manufacturer of it. Several dairy articles may be mentioned. "Westcott's Return Butter Pail" is a contrivance for sending butter to market in the best possible trim. They are eighteen dollars per dozen, hold fifty pounds each, and are made by Cady Silsby, of Seneca Falls, N. Y. Skinner's Patent Butter Worker and Churn Power, lessens and lightens dairy labour. Price, including churn and bowl, $15, E. H. Bancroft & Co. manufacturers, Syracuse, N. Y. "The Combined Paper Box and Bandage" is an invention worthy the attention of factorymen. It saves the expense of bandage, is lighter than the ordinary box, lessens trouble in cheese-making, diminishes the shrinkage, prevents the formation of thick rind on cheese, and retains the aroma in it, thereby making a richer and better article; at least so say the patentees, Utley, Kimball, and Reynolds, of Watertown, Jefferson County, N.Y. Messrs. Ralph and Co., and O'Neill & Co., of Utica, exhibited a number of Dairy requisites with various improvements in them. A Grape Trellis that can be readily tightened or loosened was exhibited by T. G. Yeomans of Walworth, Wayne Co., N.Y. A Hoisting Machine for the use of merchants, having great lifting power and yet very portable, was shown by G. F. Senter, Albany, N. Y., also a modification of it for the use of farmers as a hoisting machine and a binder of loads of hay and grain, to prevent their shifting and tilting on an uneven road. Joseph H. Chadwick's Carriage Spring Brace, a contrivance to prevent buggy springs from losing the perpendicular, was shown by G. S. Farwell, North Chill, Monroe Co., N.Y. Some articles of domestic convenience were on the ground, among them "Galvanized Portable Ovens," (to surpass the old-fashioned brick oven,) made by G. S. Blodgett & Co., Burlington, Vt.; a "Vegetable Grater," for grating carrots, potatoes, apples, horse-radish, &c., *warranted to grate a carrot in a quarter of a minute*, made by H. Arthur, Lowville, Lewis Co., N. Y., and the "Automatic Clothes Washer and Boiler," which dispenses with friction and chemicals, drives the hot suds and steam among and through the clothes, leaving nothing to do but rinse them: patentee, W. B. Watkins, 19 Cortland St., New York.

In the mechanical department, a great variety of machinery was exhibited, and was seen to special advantage, the Society having provided ample steam power, band-wheels, &c., to enable machinists to set their machines at work. Shingle-making, planing, boring, mortising, Venetian-blind slat-splitting, stave fitting, &c., &c., rendered "Mechanical Hall" a lively and attractive place. We would suggest this as a feature that might be introduced to advantage in our own Provincial shows. It would attract both exhibitors and spectators. "Floral Hall" was gay with flowers and tempting with fruit, especially grapes, of which there was a superb collection. "Domestic Hall" was filled to repletion with a bewildering multitude and variety of articles. The display of farm waggons and carriages was very fine. Cooking, parlour, and hall stoves were shown in great diversity of size and pattern, also kitchen ranges, and furnaces for heating first-class dwellings and public buildings.

For the first time at one of these exhibitions, we encountered an official dignified with the title of "Superintendent of the Press" in the person of W. H. Bogart, Esq., a veteran editor, we forget of what paper. His business was to do the polite to visiting Editors, and we gratefully acknowledge that his treatment of us was entirely in keeping with the motto that embellished the front of his office—"*None come too early, none depart too late.*"

Toronto Veterinary School.

This valuable Institution will re-open, as will be seen by advertisement, on Wednesday, Nov. 11th, for second and third year students, and for first year students on the 6th of January, 1869. We are happy to hear of the continued prosperity of this School of Veterinary Science, the existence of which, in the Province of Ontario, is of great importance to the agricultural community. Already a large number of well-qualified practitioners have been trained by its means, who are now distributed over various parts of the country, and whose services are available to the farmer in place of the often mischievous interference of ignorant farriers. Such schools of instruction are valuable, moreover, in disseminating generally a better knowledge of the animal economy, both in health and disease. Indirectly, they educate the people as well as the profession.

The School is under the able direction of Andrew Smith, Esq., assisted by Professor Buckland, and Drs. Bovell and Thorburn.

Fall Shows.

We have devoted considerable space in the present issue to accounts of the Middlesex and London Show, and the New York State Fair, and nearly the whole of our last number was occupied with reports of the agricultural and horticultural departments of the Provincial Exhibition. It would require, in like manner, the greater portion of the present number to notice, however briefly, the numerous County and Township Shows that have been held during the past fortnight in various parts of the Province. We read of one or more in every exchange that we open, but unless some special account has been officially sent us, it has not seemed desirable to notice any one particularly. Indeed, to have done so would have involved us in a vast amount of almost unavoidable repetition, which would have been tedious to our readers. So far as we can learn, the Exhibitions have been creditable to all concerned, and give evidence of material progress. At St. Catharines, the County and Township Shows were amalgamated, and an unusually good Exhibition was the result, which will no doubt lead to a repetition of the union in that county, and perhaps to the example being followed with good effect in other sections of the Province. The Toronto Electoral Division Agricultural Society's Show, held on the 1st of the month, and which of course we visited in person, was a successful though hastily-arranged affair, and for want of suitable accommodation, destitute of any show in live stock. Throughout the country, grain and root crops have been well represented, and the quality has in general been above the average. "Superior to any previous Exhibition" has been the verdict in a large majority of the reports that have come to hand. Surely, with so much cause for congratulation, we should, after the worthy example of our neighbours in the United States, institute a day of National thanksgiving for the bountiful harvest, and other blessings of Providence, that have fallen to our lot.

☞ The Nova Scotia Agricultural Exhibition, of, which we hope shortly to receive full accounts, is said to have been very successful.

Stock Sale.—The attention of farmers generally and of stock-breeders is directed to the advertisement in our present issue of the important sale of stock to take place on Mr. Snell's farm, at Edmonton, on Wednesday, Oct. 28th. Mr. Snell's stock have attained a continental reputation, and we doubt not the mere announcement of the sale will secure a large attendance of buyers. The sale comprises Short-horn cattle, Leicester, Cotswold and Southdown sheep, and improved Berkshire pigs.

Russell County Agricultural Exhibition.—We have received an interesting account of the Exhibition of the Russell Agricultural Society, which took place at the Village of Metcalfe on Friday, Sept. 25th, and was a very successful affair. There was a good show in all the departments, a large assemblage of visitors, and some capital addresses by Hon. S. L. Tilley, Hon. James Skead, Hon. Col. Gray, of New Brunswick, and Dr. Grant, M.P., for the County of Russell. A lacrosse match was added to the attractions of the day, and the annual dinner of the Society closed the proceedings, which seem to have been altogether very satisfactory.

The American Entomologist.—We would especially direct the attention of our readers to the advertisement of this new entomological journal, which we noticed in the Canada Farmer for Sept. 15th. We would again most cordially recommend this important and useful periodical, not only to students in Natural History, but to all engaged in practical agriculture or horticulture. Persons residing in Canada can be supplied with the *American Entomologist*, postage free, by remitting one dollar to the Rev. C. J. S. Bethune (Credit P.O.), Secretary of the Entomological Society of Canada.

Agricultural Intelligence.

Meeting at Rochester—Cattle Disease.

On Wednesday evening, Sept. 30th, a meeting was held in the Osborn House, Rochester, for the purpose of considering the propriety of holding a convention with reference to the cattle plague. The following gentlemen were present:—Hon. I. S. Gould, Hon. L. F. Allen, General Patrick, Commissioners of the State of New York; Hon. C. Christie, President Board of Agriculture, Ontario; Thos. Stock, Esq., President Agricultural Association, Ontario; Hon. A. A. Burnham and Col. Denison, members of the Board of Agriculture, Ontario; and other gentlemen connected with the N. Y. State Agricultural Society.

The gentlemen from Canada attended in compliance with an invitation extended to them by Mr. Allen on the part of the Commissioners of the State of New York. The meeting was agreeable and important. There was entire unanimity of opinion as to the necessity for a Convention. It was deemed the only way to bring about uniformity of legislation with reference to this important matter. We give the following summary of the business done at the meeting.

It was resolved to recommend to the Governments of the several States and Provinces interested, that three Commissioners from each of the States and Provinces in question be appointed by them to attend a Convention to be held at Springfield Illinois, on Tuesday, the 1st December, next.

The object of the Convention is to consider the pathology, symptomatology and history of the Spanish cattle plague, and other infectious and contagious diseases to which cattle and other stock are liable, and the methods of preventing the spread of such diseases in the best possible manner, with reference to the interests of the producer and consumer, and also to consider the sanitary requirements of the community with reference to the feeding and rest of animals "in transitu," and the best methods of inspection, slaughtering and preparing for market.

The Convention will prepare the draft of a law which shall provide for the accomplishment of all these objects, to be submitted for enactment to the Legislatures of the States, Territories and Provinces represented in the Convention.

Immigration Returns.

The following figures give some interesting information relative to the number of immigrants who have arrived at Toronto since the 1st of January last. The statement is obtained from the records of the emigration office in this city, an employé of which watches the arrival of the trains and boats. The large number of Germans and Scandinavians who pass here have, of course, only selected the Quebec route to reach their destination, which is arranged before starting on their journey from the old world. A large proportion of the last named were Mormons, on their way to Utah. The nationality of the immigrants was as follows:—English 1,692; Irish 964; Scotch 1,231; Germans 7,845; Norwegians 10,390; Danes 1,635; Scandinavians 457.

In this connection it is well to state that the immigrants lately sent out by the East End Society of London all found employment on their arrival. Nearly all were employed before reaching here by one or two gentlemen on the line of the Northern Railway.

The arrivals in each month and the proportions going to Canada and the United States are shown in the following table:—

	Canadians.	U. S.	Total.
January	50	52	102
February	67	26	93
March	100	48	148
April	165	340	505
May	465	4,408	4,873
June	768	6,987	7,755
July	765	5,625	6,390
August	721	2,689	3,410
	3,101	20,175	23,276

Showing a total passing this point of 23,276 in eight months.

The following show the destination of the different races:—

	Canada.	U. S.	Total.
English	1,588	304	1,692
Irish	602	364	966
Scotch	1,047	184	1,231
Germans	60	7,785	7,845
Scandinavians	4	11,051	11,055
Danes	0	457	457
Other countries	0	30	30
	3,101	20,175	23,276

☞ More than 10,000 people, says the *Times*, were present at the County of Peel Fall Fair, held last week at Brampton.

☞ The sinking of the salt test well at Port Elgin proceeds satisfactorily. It is now nearly six hundred feet deep.

☞ Mr. Joseph Parkinson sold a Durham cow and calf recently to Mr. Aitcheson, Guelph Township for the sum of $230; also two ram lambs for $50.

☞ Bears are numerous and audacious around Ottawa city. Last week a fine prize cow belonging to Mr. James Armstrong, was selected out of a herd at pasture, and mangled by them.

Peppermint Culture.—Lyons, Michigan, has a hundred acres of peppermint under cultivation, and has made this year a thousand pounds of pure oil, and is still at it. The oil is worth $8 a pound.

Wintering Cattle in Quebec.—The Montreal *Witness* says that the scarcity of fodder in Ontario, as compared with the greater part of Quebec, has induced speculators to buy up droves of young cattle in the western province and take them there to winter.

Crops in Great Britain.—The British Board of Trade has made known the chief results of the official Agricultural returns of Great Britain for 1868. The number of acres in wheat for the current year was 278,384 more than in 1867; an increase of 8.2 per cent. The decrease in the breadth of barley sown was 109,963 acres, or 4.9 per cent. In live stock—Cattle show an increase of 8.5 per cent; sheep of 6.1 per cent; pigs 2.2 per cent. The land under potatoes in Great Britain this year is 539,554 acres against 492,217 in 1867. The acreage under hops is slightly increased.

United States Hay in Great Britain.—In consequence of the existence of the cattle disease in the States, extra precautions have been taken in Great Britain with regard to the introduction of American hay. Early in September the official *Gazette* contained an Order in Council made on the 15th of that month, under which hay brought from any port of the United States to any port or place in the United Kingdom is not to be landed without a license duly obtained from the Privy Council, and its use, even under these conditions, is restricted to horses.

Large Farms.—Twoe nterprising gentlemen, of Harrison county, Ohio, have purchased a township six miles square in Nebraska, of Government land, and propose to convert the whole into one grand farm of 23,040 acres. They intend to inclose it with a hedge of osage orange 24 miles in extent, and will put up cross hedges 12 miles in length. They will hire all their labour, and use the most improved agricultural machinery, intending to put the whole farm into wheat as fast as possible. It will require 20,000 bushels for the seed of such a farm. A colony is also being formed in Chicago, under Mr. Amos Duffield, for the purchase of another township in Nebraska for the same purpose.

Short Horn Sales.—Mr. John Snell, of Edmonton, sends us the following list of his recent sales of Short Horns:—To Jas. S. Thompson, Whitby—"Fairy Duke," by "Duke of Bourbon," 184; dam "Fairy," by "Prince of the West," 588; and "Rose of Allandale," by Duke of Bourbon," dam "Emma," by "Cheltenham," 655.

To Mr. Jonathan Knaggs, of Bothwell—"Bell Duke of Solway," by "Duke of Bourbon," dam "Mary Grey," by "Baron Solway," 45; and "Annie Laurie," by "Duke of Bourbon," dam "Kitty Clover," by "Baron Solway," 45.

To Mr. Wm. Smith, Whitby—"Diamond Duke," the second prize bull calf at Hamilton, by "Duke of Bourbon," dam "Regina," by "Prince of the West," 588.

To Mr. R. B. Ireland, Nelson—"Kentucky Baron," by "Baron Solway," dam "Queen Mary 5th," by "Grand Duke," 2933 A. H. B.

Entomology.

A Man-slaying Caterpillar!

"Death in the Tomato Patch.—Most persons who are familiar with the tomato plant know that it is infested—more in some localities than in others—by a huge green worm, two or three inches long, and as large as a man's little finger, its forehead armed with a stiff horn or spike. Various reports have of late been afloat in the papers with reference to the poisonous character of the 'bite' of these worms; but we suppose the danger, if there is any, lies in the sting or puncture from its horn, and not in the bite. A few days since we heard an account of a case which occurred in Red Creek, Wayne County. The family sent the hired girl to pick some tomatoes, and while so engaged she felt a sting like the sting of a bee in her hand. In a short time the poison seemed to have penetrated to every part of her system, and she was thrown into spasms, her movements representing those of the worm. In her most violent periods it required the efforts of two or three persons to hold her. She was alive at last accounts, though it was not thought possible for her to recover. So says the Auburn *Advertiser*."

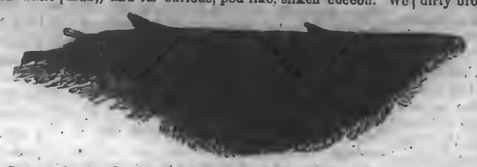
Every autumn a similar wonderful story to the above goes the rounds of the newspapers, and strikes terror into the hearts of the tomato-gatherers. Upon what foundation of truth, if any, these statements rest, we have never been able to discover, and yet, from their constant recurrence, one would think that there must be something at the bottom of them. The caterpillar in question is, we believe, perfectly harmless; we have frequently handled them, and other similar larvæ, with perfect impunity. It is absolutely impossible for the insect to hurt any one with its so-called "sting," which is simply a thorn-like horn incapable of penetrating the flesh, and situated not on the *forehead* of the caterpillar, but quite at the other end! We have often tried to force this horn into the skin of our hands, but never found it stiff enough to make a puncture; even, however, if it were to pierce the flesh, it could do no more harm than the prick of a coarse pin, as it is furnished with no poison or "noxious distilment" of any kind. The insect referred to is the caterpillar of either *Sphinx Carolina*, which is not found in this country, or *S. quinque maculata*, common here on the potato and tomato.

It is not at all unlikely that, in the case referred to above, the girl was stung by a ground-wasp or hornet, whose sting produces sometimes very serious effects, and that the innocent tomato-worm, on account of his large size, ugly looks, and threatening horn, was pronounced the culprit instead. Before believing the latter's guilt, we should wish to hear of one single well-authenticated case that occured in the presence of an entomologist, or one accustomed to notice the differences between small objects in nature, and who could distinguish, at any rate, between the head and tail of a caterpillar.

The Cecropia Emperor Moth.

Non-collectors of insects, who see for the first time specimens of this and other large native insects, are usually filled with amazement at their size and beauty, and scarcely credit the statement that they are veritably indigenous to Canada. Being nocturnal in their habits, the Emperor Moths—of which we have five species in Canada—are but seldom seen except by collectors and others who take the trouble to rear them; their cocoons and caterpillars, however, are much more frequently met with; the former, in the case of the moth before us, being especially conspicuous on the leafless boughs of apple and other trees.

According to promise, we now give a life-size illustration of the Cecropia Emperor Moth, (*Samia Cecropia*, Hüb,) and its curious, pod-like, silken cocoon. We



lately (C. F., Sep. 15, p. 278) gave a brief description of the egg, caterpillar and cocoon of this magnificent insect; the illustrations now presented will enable any of our readers to recognize the moth itself, and will perhaps encourage them, when they find one of the cocoons, to endeavour to rear the insect, and obtain a live specimen for themselves. All that is

necessary is to keep the cocoon in a cool room during winter, shade it from any direct rays of the sun, and take care when it does come out, (about the end of May or beginning of June,) that it does not fly out of the window. The best plan is, perhaps, to place the cocoons in a gauze-covered box, and keep them in a room where there is no fire; when warm weather comes on in the spring, the box should be examined daily, and the specimens removed as soon as their wings are fully expanded; they can easily be killed with chloroform or ether.

The upper figure represents the cocoon, which is composed of strong tough silken fibres, closely agglutinated together; after being boiled for some time in an alkaline solution, the silk fibre can be unwound and made use of, producing a very durable fabric. Another moth, however, of the same family (*Telea polyphemus*, the Eyed Emperor,) is the best for this purpose, and is now being largely raised by an enterprising gentleman in the United States.

Beech Aphides.

To the Editor of The Canada Farmer:

Sir,—Enclosed herewith I send you a box of specimens of insects infesting the beech trees in the neighbourhood of Kempenfeidt Bay, Lake Simcoe. They fairly cover the leaves and branches, and some of the trunks of the trees, so as to become a serious annoyance to those parties working in the woods. Will you please name them in the next number of the Canada Farmer, and give any items of their history which may be known to you.

ALLANDALE.

Innisfil, October 8, 1868.

Note by Ed. C. F.—The specimens referred to above are a species of Hemipterous insects belonging to the *Aphididæ*, or Plant-lice family. They are of a dirty brownish colour, varied with dark olive above, about a tenth of an inch long, of a somewhat oval shape. Like all the "bug" tribe, they are furnished with a long proboscis, through which they suck up the sap and juices of plants; their enormous numbers render them very injurious to vegetation. They are probably the most prolific of all insects; of one species it has been computed that a single female produces ninety young ones, all females; these ninety produce 8,100; and so on till the eighth generation reaches the almost incredible number of 441,461,010,000,000; there are eleven generations in the year. Were it not for the many carnivorous insects and other creatures that prey upon them and keep them in check, they would destroy the whole vegetation of the world in a short time. We have frequently referred to the carnivorous insects that feed upon the various species of plant-lice, but we cannot too often direct attention to them and plead with our readers for the preservation of their lives. The different species of lady-birds (*Coccinella*) both in their larval and pupa states, are the most useful of all; fortunately, they are well known to all, even children, and are usually spared the fate that awaits almost all insects that come in people's way. We know of a field of hops saved from destruction by their means.

Notes on a New Grape Insect.

To the Directors of the Fruit Growers' Association of Ontario.

Up to the present season we have not been aware of the presence in Canada of any insect injurious to the fruit of the grape. In the United States—at least in parts of Illinois and Ohio—they have been troubled with a grape curculio (*Coliodes inæqualis*), a small oval snout beetle, about one-tenth of an inch long, and of a dull black color, with grey markings. These have punctured the fruit and deposited an egg in the puncture; this egg has in a short time produced a larva, which has burrowed into the flesh of the fruit and destroyed it, causing it usually to drop from the vine before maturity.

It now becomes my duty to chronicle the advent of an insect which I believe to belong to the same family, although much smaller; and while it has never been seen, as far as I know, by any previous observer, it must have been carrying on its destructive mission for years past.

In August of the present season I observed many of the berries on a Clinton vine in my garden shrivelling. Thinking at first it was due to the excessive heat of the summer, I paid little attention to it; but finally this abnormal condition prevailed to such an extent as to excite me to a close investigation as to the cause. On opening the berries, I found in the smaller ones usually one seed very much swollen, and one or more dwarfed and imperfect. In some larger berries I found two large seeds, both much swollen and rather soft. In most instances a dark spot was observed on some part of their surface. When these seeds were cut open, the kernel was found to be almost entirely consumed, and the cavity occupied by a little white grub, from one-fifteenth to one-twelfth of an inch long, without legs, and with a pair of brownish hooked mandibles or jaws.

From its appearance, I am of opinion that it is the grub of a small species of curculio, or snout beetle, which will probably enter the pupa or chrysalis state within the seed, and when perfected, gnaw its way through its hard enclosure, and escape to renew the work of destruction. The parent insect probably punctures the grape and deposits the egg under the skin. Many of the grapes have a small scar, as if resulting from an operation of this sort. The young larva, as soon as hatched, must work its way directly to the middle of the fruit, and there enter the seed while young and soft. There is no appearance in the pulp of the fruit of its being channelled or eaten.

Fully ten per cent. of the fruit on the Clinton vine was destroyed by this pest; and I had concluded that here the damage ended, and that by destroying the injured berries I should be tolerably safe against future attacks; but on a closer examination, I found that some of the seeds in the ripe fruit were also occupied by this unwelcome tenant. To ascertain the extent of the insect's work in this department, I examined the seeds from one hundred berries picked at random from different branches on the vine, and found about ten or eleven per cent. of the berries affected. In every case where the berry ripened, there was at least one good healthy seed in it, sometimes two, associated with the diseased one, and this healthy seed had enabled the berry to mature.

Around this Clinton vine, and all within a few feet of it, I had fruiting the Isabella, Hartford Prolific, and Concord. No shrivelled berries could be found on either of these vines, nor any diseased seed in the ripened fruit of either Hartford or Concord; but in the Isabella about three per cent. of the berries contained an injured seed. From these facts, I infer that grapes of the Clinton class, with thin skins, are more liable to injury from this insect than thick-skinned varieties, such as Concord and Hartford.

While on a visit to Mr. Chas. Arnold, of Paris, in the middle of September, I found his vines affected even worse than my own; Clinton, Delaware, and Mr. Arnold's new seedlings, were all suffering. I also found the insect in Hamilton.

In the present state of our knowledge, it is premature to talk of remedies, further than that of destroying such berries as are manifestly injured. We must learn a little more about our enemy before we can expect to combat him successfully. Time will disclose its history and identity; in the interval it will be interesting to know how far its operations extend. Should this meet the eye of any who have observed effects which might be attributed to its agency, they would confer a favor by sending me specimens for identification. Those desiring a more scientific and accurate description of this larva, will find it in the third number of the *Canadian Entomologist*, edited by the Rev. C. J. S. Bethune, Credit, Ontario.

W. SAUNDERS.

London, October 6th, 1868.

Address of the President of the Fruit Growers' Association.

Delivered at the annual meeting at Hamilton, Sept. 22, 1868.

Gentlemen of the Fruit Growers' Association of Ontario:

Owing to the changes which have taken place since our last annual meeting, brought about by the introduction of sections 32 and 33 of the Act 31st Vic., chap. 29, altering the status of this Association, it occurred to me that a short review of its past history, with a few remarks touching its present position, might not be considered an inappropriate subject for an address. Such a review would also afford me an opportunity to bring fresh to our memories the names and some of the acts of those men who first organized and sustained it. Unmistakably, it seems to me, they were animated with a desire to develop Canadian fruits, to advance the morals of the people, secure their happiness and health, promote industry, and establish a love for home; and may I add among the many advantages of this pursuit, it opens the heart to the study of nature, and thus reveals some of these Divine truths which master the fear of death. Thus, while while we justly rejoice in the prosperity of this society, we shall be reminded of those who started with us, but have since "gone home to their Father's house, and now roam on the banks of the river of peace."

As public benefactors, they deserve a tribute of respect. Among these we must honour the name of the late Judge Campbell, of Niagara, who was elected first President, and entered upon his duties with that true patriotic zeal which stamped the society's future success; and with him let me mention the name of our highly esteemed citizen, the late Dr. Craigie. These gentlemen by their united and personal efforts gave this society birth, and sustained it in its infancy. Long may we remember, with heartfelt gratitude, these departed friends. I can fancy they are able to see, from their rest in the bosom of God, that the good deeds of just men live after them.

One of the first steps taken by the founders of the Association was to procure the assistance of certain zealous fruit growers possessing similar tastes, many of whom I am pleased to see assembled here to-night—men who started at the commencement of the work, and still continue to labour for the advancement of the art and science of fruit culture, and thereby for the good of the public. I feel honoured in having my name recorded side by side with these men in the society's journal, as a co-worker. They held their first meeting on the 19th day of January, 1859, in the Board Room of the Mechanics' Hall, in the city of Hamilton, not quite ten years ago. This certainly is not a long time for a society to be placed upon its trial in establishing public taste, particularly when we consider that the formation and working of any new undertaking is most frequently attended with incidental delays. Our society cannot claim exemption from this disadvantage. It is only a matter of surprise that it should have overcome so many difficulties; these were presented in the death of the first President, the distances separating its members, and the necessary expenses entailed upon each in travelling to and from their places of meeting, and in having no recognized means to publish its proceedings excepting that supplied by private liberality. There were eighteen gentlemen present at this first meeting. After the chairman and secretary were appointed, it was unanimously resolved to form a Fruit Growers' Association for Upper Canada. A constitution was agreed upon, and by-laws carefully drawn and passed. After having done this they proceeded to appoint their officers, when, by common consent, Judge Campbell was received as first President; Dr. Hurlburt, 1st Vice; Mr. George Leslie, 2nd Vice; Arthur Harvey, Recording Secretary; J. D. Humphries Corresponding Secretary; and Edmund Kelly, Treasurer. These, then, were the first gentlemen who took upon themselves the responsible duty of conducting the affairs of the Association. But we do not see by any record in the minute book that Judge Campbell ever had the pleasure of presiding at any subsequent meeting. The society sustained in his death so great a loss that there was no further meeting, or effort taken to secure one, for nearly two years thereafter. But at length, through the efforts of Dr. Craigie, the members from their different points of residence were once more called together on the 21st day of September, 1860, during the time of the Provincial Exhibition. At this meeting the first Vice-President, Dr. Hurlburt, took the chair, and Dr. Craigie acted as Secretary, in the absence of Mr. Harvey. Only nine members presented themselves; there was no business transacted of any public importance. They resolved to adjourn and meet again on the 24th of the following month of October; each member was then requested to bring some specimens of fruits along with him, for the purpose of opening discussion. At this meeting in October, they seem to have made again a very fair start. There were seventeen present; quite a respectable show of specimen fruits were laid on the table, upon the merits of which an animated and profitable discussion took place. At the close of this session an adjournment was moved, to meet again on the 16th day of January, 1861, this being the time of the regular annual meeting for the appointment of its officers. After reading the minutes of the last two meetings, the Vice-President, Dr. Hurlburt, delivered an address on the culture of the grape in Canada. Three fruit reports were read and referred to committee; one of these came from their late lamented President. The Association then proceeded to elect its officers, when Judge Logie, of Hamilton, the second President, was duly installed, and your present able and most efficient Secretary then received his appointment to that office, which he still continues to hold, with most satisfactory attention and ability. The old constitution and by-laws were at this meeting remodeled, and made to suit the requirements of the re-organization. This highly esteemed and popular President was annually elected, and continued to hold the position with much benefit to the society, for six years. It was during his Presidency decided to hold three meetings each year for the discussion of questions relating to fruit culture, and for the diffusion of useful information. These meetings were held at St. Catharines, Paris, Toronto, Grimsby, and Hamilton. They were, at times, poorly attended, requiring push and solicitation to keep life in them, simply because the farming community, and public generally were, and are still to a great extent, unable to appreciate the benefits of such an institution in their midst. Slowly, however, these fruit-growers have gone on from year to year, gathering valuable information, which from time to time they have published, and thus people have become more interested in the better sorts of fruits, and, I am happy to say, are now rapidly acquiring an appreciative taste which does not fail to exhibit itself in a display, at some of our shows, of the very finest specimens of their kind, which may fairly challenge the competition of the world.

In the year 1863 the Association adopted a report embracing returns made by gentlemen and fruit committees, from thirty counties of Ontario, describing the several varieties of fruits most successfully grown in these localities. A new report is now under consideration by the directors, and when completed, which will scarcely be accomplished in twelve months will be a valuable directory.

Reference to the old report will enable any member to see that a large amount of labour attended the undertaking. The cost of printing alone was one hundred and eighteen dollars; this was cheerfully borne, in addition to other expenses. Thus the society has continued to utilize the fruits of Canada. Its reports, discussions and essays, have, from time to time, been printed and circulated through the columns of the Canada Farmer. But hereafter its proceedings, in addition to publication in that journal, will be printed in pamphlet form, and a copy of these proceedings presented, without charge, to every member of this Association. It will present an annual valuable record and guide in fruit culture, easily accessible for reference, and for real usefulness worth five times the amount of the annual subscription each member is required to pay.

During the Presidency of Judge Logie, the society continued to increase its membership. On the 16th day of January, 1867, the list numbered about eighty; this being the time for the general annual election of officers, upon the retirement of Judge Logie, the present incumbent received the appointment, and a re-election in January, 1868. Shortly after this date, the Government, in the Act for the encouragement of agriculture and horticulture, introduced certain clauses which enabled this society to become incorporated, under

the name and style of "The Fruit Growers' Association of Ontario," with important privileges therein set forth, one of which is the grant of three hundred and fifty dollars per annum, a very small sum compared with the amount of services and good rendered to the whole country by the encouragement of fruit production. Besides, it bears no just proportion to the grant made to each county division. I am satisfied, could the members of the House, who were in committee on the Bill, have had the subject properly explained, the grant would never have been less than seven hundred dollars per annum. This opinion is based on various reasons, some of which I propose here to mention. The Fruit Growers' Association would be able to procure and publish annually, by means of their discussions and reports, useful information, (such as would not be acquired by any single agricultural division), touching subjects of general and public interest. They would point out, for instance, the most suitable fruit trees and fruits for any given section, from which the immigrant and farmer could learn what to purchase for his particular soil and position, enabling him to secure a knowledge of these matters without the loss of years of experiment; and they would set forth the best methods of cultivation, and the proper classification of fruits, and those best suited for market purposes—matters constantly brought before the public by the debates of practical men, always the very best scource of information that can be obtained. This is of extreme importance to all classes. It is evident that the whole of the twelve agricultural divisions would participate in the knowledge accumulated by the society, and should therefore be tributary to its support. There is also connected with this Association a practical entomologist, whose reports upon injurious insects would most materially aid the whole agricultural community in their destruction. The American *Entomologist* for September, 1868, says:—"Few persons are aware of the enormous amount of wealth annually abstracted from the pockets of the cultivators of the soil by these insignificant little creatures, which in popular parlance are called 'bugs.' Scarcely a year elapses in which the wheat crop, both in Canada and the United States, is not more or less ruined by the chinch-bug, the hessian-fly, the wheat-midge or the joint-worm. It is notorious among fruit growers that the curculio has now almost entirely vetoed the cultivation of the plum, and of late this pernicious little snout-beetle has extended its ravages to the peach, and even to the apple and pear, to say nothing of these rarer and choicer fruits the nectarine and the apricot. What with the bark-louse in the north, and the apple-worm everywhere, the apple crop in North America is gradually becoming uncertain." Very much of our success in fruit culture, as also in agriculture, depends upon a knowledge of the habits and the best means of destroying insects. Already we feel that these enemies are making rapid encroachments on our labour in field, orchard and garden, and if they do not receive checks will continue to do so. As the country becomes more settled and cultivated it will require our united efforts to keep them under subjection, and were there no other reasons offered than those advanced for increased aid, they alone should be sufficient. I do most earnestly suggest that action be taken at the next session of our Legislature, to accure an increase of aid to the fruit growers to carry out these desirable objects. A moment's reflection ought to show the Legislature that in point of usefulness this Association far surpasses any one agricultural division, and therefore justly claims a support at least equal to one of these county divisions. I trust that the importance of this subject will justify this slight digression.

The Act above referred to sets forth the course to secure incorporation, and provides that hereafter the Association should be under the control of nine directors, in addition to the other officers; therefore, immediately after the passing of this Act, your Secretary set to work and procured a declaration, to be properly engrossed on parchment, and presented the same for signatures. After obtaining more than double the number required, it was sent to the Minister of Agriculture, who duly recorded it in the Official *Gazette* of the 26th of March, 1868, thus securing to the Association the stamp of legality in its future transactions, enabling it to hold property, sue for its claims, and be sued for its delinquencies—which I trust may always be few and far between.

And for the further carrying out of this Act, a re-organization was required. A constitution and by-laws were accordingly drafted and submitted to the members of this Association, at a special meeting called for the purpose of having them adopted, with such amendments as the meeting considered advisable. This took place on the 15th day of May last, in this building. After some slight amendments they were adopted. The meeting then proceeded to appoint its officers and directors. A full statement of these proceedings was recorded in the CANADA FARMER, issued 1st June, 1868. Since then the directors have assumed the control of its affairs. They have met several times in the meanwhile, for the transaction of business, which has also been duly recorded in the CANADA FARMER. There is no doubt that these gentlemen, in their printed report, required by the Commissioner of Agriculture, will be able to show they have not been idle in furthering the interests of this Association.

They are charged with the important duty of enlarging its boundaries, zealously guarding its interest, making it at all times worthy of the confidence of the public, and a medium of correct and reliable information on all matters touching fruits, and in building up for the Province of Ontario a taste for the noble art of horticulture. They have the right, if so disposed, to establish in connection with this Association a horticultural library and museum of insects. This, in many respects, would be most desirable; it would inculcate a taste for horticultural reading, and eventually enable the public, under the patronage of this society, to receive monthly a practical horticultural magazine. As it stands, there is not one now issued in the Province, and the public are dependent on American enterprise for this most useful literature. The services of a gentleman well skilled in entomology have already been secured. All agricultural and horticulturalmen throughout the Province will look to this Association for information on all matters touching fruit culture, and it will rest with the directors to a great extent to meet this want. But there is also a duty resting upon the general public, without the performance of which this society will be much crippled in its efforts to do good. I refer to the facilities which may be offered by the people of any place in securing proper accommodation for its meetings, hereafter to take place three times a year by appointment of the directors. If they should lack in offering these facilities, or in attending these meetings, or in sending invitations to the society to meet in their respective places, I say that a lack of reciprocal appreciation will to a great extent hamper the usefulness of the Association. The benefit is universal, and therefore all should feel a mutual and personal interest in its success.

Our Railways are justly considered as incorporations which advance the interests and wealth of a country, and in affording facilities to the members of this Association to get to and from their places of meeting, at reduced fares, are most nobly confirming the consideration, besides advancing their private interests; for in proportion as the public become engaged in the production of fruits, it will have a clear tendency to increase both travel and freight, and offer great inducements to those who have a strong desire to become members, but can ill afford to pay full fare, to be present at these annual meetings. I have therefore great pleasure in stating that the Manager of the Great Western Railway, with his usual liberality, has extended to the members of this Association the privilege of travelling to and from our next meeting, to be holden in St. Catharines, in October, at reduced fares.

Probably one of the most important objects this society could pursue and seek to accomplish would be the establishment of a test garden, wherein might be proved the qualities, productiveness, and hardiness of fruits. It would afford to the hybridizer and producer of new varieties a safe and true test of merit. Such a garden, after the first cost of purchase, underdraining and fencing, could and should be made self-sustaining; but with the society's present limited aid, its members can only look forward with hope to the time when, with an increased grant, they will be able to carry this object into effect.

I may say, in conclusion, that this Association can only be considered in its youth; for until the passing of the new Agricultural Bill, it had no recognized aid to enable it to disseminate its deliberations. It has since its reorganization doubled its membership, offered premiums in the shape of diplomas, and money rewards for essays, that will tell their own story at the next annual meeting. Already several committees have been solicited to inspect and report on new fruits originated in Canada—some of them true hybrids, produced by the commendable efforts of some of its members. I feel that this address has already been sufficiently extended, and will close by expressing an earnest hope that at our next annual meeting we shall be able to show many steps in advance of our present position.

RUSSIAN HORTICULTURE.—Russia, the country of implacable winters, contains in its hot-houses the finest flowers in the world. The Muscovites possess in a high degree the love of the Goddess Flora. This is the only superiority St. Petersburg possesses over the other capitals of Europe. Thus the public will learn without astonishment that the Czar has decreed for 1869 an International Exposition of Horticulture, to take place the last of May

The Household.

The Ladies and the Canada Farmer.

To the Editor of THE CANADA FARMER:

SIR,—I have been a constant reader of your journal since its first publication, now nearly five years, and I am better pleased with it every year; in fact I could hardly get along without it, as every number has something interesting to practical farmers; but like many other periodicals, it has not attained perfection. Every close reader will notice that it lacks something, viz: contributions by the ladies. I do not remember seeing six articles specially contributed for the CANADA FARMER, by the ladies, since its commencement. It may be suggestive and profitable to inquire into the reasons for this lack of co operation—if not of interest—on the part of our fair friends. It cannot be for want of a sufficiently cordial invitation on the part of the editor, or because their contributions have been declined, for they have been repeatedly solicited to lend their aid to its pages, and anything that has come from them has been most emphatically welcomed. Neither can it be because they lack the ability of writing articles suitable for publication. The charming productions of female pens sufficiently attest the literary aptitude of the educated portion of the fair sex; and there are doubtless many such to be met with amongst our farming community, who are every way qualified to instruct and please, if they would only put forth the effort. Perhaps they are deterred by their natural timidity from the formidable publicity of appearing in print. Or it may be that, with an amiable diffidence, they presume that they could communicate nothing worthy of publication, that what they know is already known to all the readers of the paper. Some may be waiting for others to set the example; and it is just possible that some may be unwilling to impart their household information, lest by making it common property they deprive themselves of their fancied superiority.

Be the reason what it may, this reticence on the part of the rustic fair is much to be regretted; and it would be well if they could be stirred up to contribute their quota to enhance the interest and value of the CANADA FARMER. Perhaps if they knew that a fair proportion of the matter in the American agricultural papers was contributed by female writers, they might be incited to a little honest rivalry. I am satisfied there are hundreds of farmers' wives and daughters who could give interesting information, practical instruction, and sound advice on household affairs, and even on subjects of higher importance. If such would only write, and give others the benefit of their experience and knowledge, they would confer immense obligations on thousands of readers of the CANADA FARMER.

CULTIVATEUP

Ontario, Sept., 1868.

☞ Among recent useful inventions is an ironing glove to protect the hand from heat when ironing. The under part is composed of several thicknesses of flannel. Any old glove could easily be converted into such a simple yet obviously convenient and effective guard.

ADVICE TO LADIES.—Josh. Billings, in his advice to a young lady as to how she should receive a proposal, says: "You ought tew take it kind, looking down hill with an expreshun about half tickled and half scart. After the pop is over, if your luvyer wants tew kiss you I don't think I would say yes or no, but let the thing kind of take its own course."

RATS—HOW TO FIX THEM.—Chloride of lime has frequently proved a sure thing to drive rats away from any place infested by them. An ounce of it, scattered in the place where they come to feed, or wrapped in a bit of muslin, and put in their holes, where it acquires dampness, produces a gas that is not offensive to man but is to the rats. If chloride of lime is moistened with muriatic acid, and placed in a drain, vault or cellar, and closed from the air a little while, the rats will depart, because it will be death to remain. This is also a good disinfectant, and will, for a time, cure the effluvia of a dead rat. One application of chloride of lime to rat holes has driven them away for a year, and on their return, a renewal of it started them again.

Miscellaneous.

The Use and Care of Edge Tools.

As the pocket knife comes from the manufactory or store its edge is unfit for use; it may cut butter or cheese, possibly soft wood, but it will not pare finger nails nor sharpen lead pencils. It needs the hone and strop to produce an effective edge. And in the proper use of the hone or oil-stone many are quite ignorant. First, nothing but a good oil-stone is fit for sharpening a knife blade. Ordinary "whet stones," mere sand stones to be used with water; or dry, are too coarse; they are but fixed grindstones, and rapidly abrade the substance of the blade without giving it an edge. The Turkish oil-stone is greatly affected by some, but it is quite hard, and fit only for giving the finishing touch to very delicate tools. The Washita, or Ouachita stone, we prefer for pocket knives and for ordinary tools. The philosophy of whetting or honing is a gradual and mutual abrasion of the particles of the stone with those of the steel. The oil, with its glutinous quality, holds these commingled particles so that by the movement of the blade they act on the steel and abrade it very gradually. If the stone is too hard it quickly glazes, and the blade slips over a perfectly smooth surface, producing no action on the hardened steel; if too soft, the stone allows the edge of the blade to disintegrate its surface and heap up a ridge of quartz-like or flinty particles, which produce a round or "stunt" edge, that in time must be removed by the action of the grindstone. One accustomed to sharpening knife blades can easily tell when the operation of honing is going on properly, and only experience can fully teach the process. There should be a certain feeling of resistance in the operation. The motion for whetting or honing should be circular; not as in stropping a razor, merely back and forth. The educated fingers will readily feel when the blade bears properly on the surface of the stone, and will guard against the mere abrasion of the back and the cutting in of the edge. This art can be only acquired by practice.

Few can hone a razor. Some barbers have the happy faculty, but generally it is an art little understood. The stone should be a fine Turkish stone, perfectly clean, and the oil used should be purified porpoise or nice sperm oil; pure olive oil is good. The blade of a razor is concave. The wedge-like edge extends in its bevel but a little way back. In honing a razor the fingers should feel the back as well as the edge of the blade bearing; the back protects the edge. The motion should be the same as in honing a knife blade, circular. Few can hone a razor properly on the first trial.

In stropping razors most people fail. They will use a too yielding medium, which rises suddenly as the edge passes over it, and undoes what has just been done. Many turn the razor or knife blade on its edge. Unless the blade is lifted clear from the strop, just before turning, the tendency is to strop off the edge already on. A blade should be drawn from heel to point, starting at the heel and drawing it diagonally to the point, and should be always turned on its back.

Oil-stones, as seen in the shops, are frequently worn concave. It is unnecessary to say that stones in this form will not produce a true edge. If the workman has not acquired skill enough to wear the stone evenly, as much at the ends as in the middle, he should occasionally grind the oil stone and reduce its surface to a level.

In the machine shop and the carpenter's shop, wherever edge tools are used—the oil-stone is invaluable. It should, however, be used with discretion. If the tool is soft a short bevel should be given to the edge; if hard, it will stand a very thin edge, but the practice of producing a temporary edge by honing or whetting will not give even the best present result, and will necessitate a frequent resort to the grindstone, the office of which is only preparatory to the production of a good cutting edge.

The use of rapidly abraiding substances, as fine quartz, emery, etc., is ruinous to good tools; and the continual employment of the grindstone not less so; while a judicious use of a good oil-stone will keep tools in order until they are almost worn out.—*Scientific American.*

The Old Negro's Logic.

A CLERGYMAN asked an old servant his reasons for believing in the existence of a God.

"Sir," says he, "I see one man get sick. The doctor comes to him, gives him medicine; the next day he is better; he gives him another dose; it does him good; he keeps on till he gets about his business. Another man gets sick like the first one; the doctor comes to see him; he gives him the same sort of medicine; it does him no good, he grows worse; gives him more, but he gets worse all the time till he dies. Now that man's time to die had come, and all the doctors in the world can't cure him.

"One year I work in the corn-field, plough deep, dig up grass, and make nothing but nubbins. Next year I work the same way; the rain and dew comes, and I make a good crop.

"I have been here going hard upon fifty years. Every day since I have been in this world I see the sun rise in the east and set in the west. The north star stands where it did the first time I ever saw it; the seven stars and Job's coffin keep on the same path in the sky, and never turn out. It ain't so with man's works. He makes clocks and watches; they may run well for a while, but they get out of fix, and stand stock still. But the sun and moon and stars keep on the same way all the while. There is a power which makes one man die, and another get well; that sends the rain, and keeps everything in motion."

What a beautiful comment is here furnished by an unlettered African on the language of the psalmist: "The heavens declare the glory of God, and the firmament showeth his handiwork. Day unto day uttereth speech, and night unto night showeth knowledge."

A CURIOUS EXPERIMENT.—Take a piece of pasteboard, about five inches square, roll it into a tube with one end just large enough to fit round the eye, and the other end rather smaller. Hold the tube between the thumb and finger of the right hand (*do* not grasp it with the whole hand); put the large end close against the right eye, and with the left hand hold a book against the side of the tube. Be sure and keep both eyes open, and there will appear to be a hole through the book, and objects seem as if through the hole instead of through the tube. The right eye sees through the tube, and the left eye sees the book, and the two appearances are so confounded together that they cannot be separated. The left hand can be held against the tube instead of a book, and the hole will seem to be seen through the hand. *Mark Lane Express.*

Markets.

Toronto Markets.

Canada "Farmer" Office, Oct. 13th, 1868.

FLOUR AND MEAL.

Flour.—The market is unchanged. No. 1 super. has been offering at $5 15, and a sale of 100 bbls. was made on Change at that figure. The demand was limited, and there was not much desire to buy. 100 bbls. "Golden Drop" sold at $5 50. In extra and superior there is nothing whatever doing. Extra would not bring over $6. Business is entirely confined to retail lots.

GRAIN.

Wheat—The market for spring continues very dull. A car lot sold to-day at $1 14 f. o. b. There is, however, only a very limited demand at that price, and to effect sales of lots a reduction in price would have to be made. On the street market Midge-proof and Spring sold at $1 13 to $1 18. Fall wheat was offering freely, and as holders reduced their views, some sales were made. A car lot sold at $1 30; 1 car at $1 29 f. o. b.; 1 car inferior at $1 25, delivered; and 1 car very choice at $1 36, delivered. On the street market white Scules' is selling at from $1 30 to $1 35, and Red Winter at from $1 13 to $1 16.

Oats—There has been nothing doing to-day in car lots. Prices remain nominally unchanged at 46c. to 48c. On the street market a few loads sold at from 48c. to 50c.

Barley—The market was excited and higher; a considerable quantity in cargo lots changed hands during the past few days at advanced prices. The market has been completely "cornered;" almost all the lots in the market are now held by one firm. Large lots are now held firmly at $1 50, and several sales have been made at that price. The receipts on the street market continue very light; street prices have advanced; $1 44 was paid in the afternoon for the few loads coming in.

Peas.—There is no change in the market. We heard of no sales of car lots. There are buyers at 90c f. o. b. On the street market 92 cents were paid.

HAY AND STRAW.

The market has been fairly supplied. Hay has been selling at from $12 to $15, and straw at from $7 to $10.

PROVISIONS.

Pork—Unchanged; only a few lots on the market, which are held at from $25 50 to $26.

Butter—As is usual on Mondays, there was not much doing to-day in this article. Prices remain unchanged. Ordinary store packed is selling at from 17c. to 20c.; fair to good lots would bring 21c; and straight dairy 21½c. to 22c.
